NOTES: Dates are given in days and decimals of a day U.T. 1 nautical mile = 6,080 ft. = 1·853 km. Perigee and apogee heights for *Sputniks* are over an earth of radius 3,435 n.m. and for U.S. satellites over an earth of 3,442 n.m. Argument of perigee is the angle from northward crossing of the equator to perigee, measured along the orbit. The orbital values for the *Sputniks* are from British observations and theory. Those for the U.S. satellites have been compiled from a variety of sources. It is not known whether *Discoverer* 1, launched February 28, 1959, achieved orbit; it was, nevertheless, designated 1959β. * Indicates satellites no longer in orbit.

NEWS and VIEWS

International Meteorological Organization Prize, 1959: Prof. J. Bjerknes

THE Executive Committee of the World Meteorological Organization has this year awarded the annual prize, provided by funds left by the International Meteorological Organization on the formation of the World Meteorological Organization, to the eminent Norwegian meteorologist, Prof. J. Bjerknes, who is now professor of meteorology at the University of California, Los Angeles. Prof. Bjerknes is known to meteorologists everywhere for his work, in conjunction with his father, the late V. F. K. Bjerknes, T. Bergeron and H. Solberg, in the initiation forty years ago at Bergen of the technique of frontal and air-mass analysis in weather forecasting. With the same meteorologists as those noted above, he collaborated in the writing of a major text-book on dynamical meteorology, "Physikalische Hydrodynamik", published in 1933. Before the War he carried out much research into the structure of depressions, as revealed by the release of a large number of sounding balloons at frequent intervals from one place for a number of hours, and with the dynamics of convection in the atmosphere. Since the War he has been particularly concerned with research into the general circulation of the atmosphere. He was professor of meteorology at the Geophysical Institute in Bergen from 1919 until 1931 and went to Los Angeles in 1940. In international scientific work he has been both secretary and president of the Association of Meteorology of the International Union of Geodesy and Geophysics. British meteorologists, to whom he is well known as an honorary Fellow (1932) and Symons Gold Medallist (1940) of the Royal Meteorological Society, welcome this award to one of their most distinguished, genial and unassuming colleagues.

Chemistry in Relation to Medicine at Edinburgh: Prof. G. F. Marrian, F.R.S.

PROF. G. F. MARRIAN, who is to retire from the chair of chemistry in relation to medicine in the University of Edinburgh, moved from Toronto to Edinburgh in 1938 to succeed Prof. George Barger. He had already established his reputation by the isolation of pregnanediol in 1929, œstriol in 1930 and œstriol glucuronide in 1936. He gathered a group of workers and proceeded to isolate a considerable number of new products of steroid metabolism, notably 16α-hydroxyœstrone, and more recently he has also worked on the metabolism of adrenal cortical hormones. He developed new methods of estimation of steroids of clinical importance for diagnostic purposes. On his advice, the Medical Research Council set up a Clinical Endocrinological Research Unit at Edinburgh and he took a considerable part in its management and direction. Latterly he served on the Agricultural Research Council, the Medical Research Council and the Advisory Committee for Medical Research in Scotland.

With the institution of a six-year curriculum at Edinburgh in 1949, Marrian took over the teaching of biochemistry to medical students. For them his lectures provided an exceptionally clear and illuminating introduction to the subject. After a few years, the teaching of chemistry to medical students, which was previously the Department's main teaching duty, was handed over to the Department of Chemistry, so enabling the Department of Biochemistry to undertake the teaching of biochemistry to dental and to veterinary students and to strengthen the science courses in biochemistry, which now include a flourishing honours year.

Prof. R. B. Fisher

DR. R. B. FISHER, who is to succeed Prof. Marrian at Edinburgh, took the Final Honour School of Animal Physiology in the University of Oxford in 1929, became a departmental demonstrator immediately and a University demonstrator in due course. For more than twenty-five years he was one of the most sought-after teachers of biochemistry in Oxford. Undergraduates reading medicine learned from him a critical approach to the literature and an eye for nonsense which left a permanent stamp upon them. Colleagues in many biological departments made a habit of asking for his criticism and advice on their papers, on their design and statistics. He did the same useful service officially as an editor both on the *Journal of Physiology* and the *Biochemical Journal*. He was away from Oxford for some years during the Second World War, directing an Air Ministry Group concerned with the design and analysis of strategic bombing. He belongs to the select race of chemical physiologists, and prefers to work on unquestionably living cells. He has demonstrated creatine synthesis in the surviving heart, and is using the perfused heart for work on the effects of insulin on permeability. He devised a method of studying absorption in surviving small intestine and has written a book on "Protein Metabolism", which is widely known as a critical appraisal of accepted views.

Fisheries Research: Dr. H. A. Cole

DR. H. A. COLE, who took up his duties as director of fisheries research on May 1, in succession to Mr. R. S. Wimpenny (see *Nature*, 181, 159; 1958), joined the Ministry of Agriculture, Fisheries and Food as an assistant naturalist in 1933 when he was appointed to the Laboratory at Conway. During the period up to the war he was largely concerned with an examination of the development and setting behaviour of oysters in tanks and of the incidence of parasites. In the war he was seconded to the Yorkshire (West Riding) War Agricultural Executive Committee, serving as a deputy chief executive officer. When he returned to the Conway laboratory in 1946 he resumed and extended his interests in oyster culture in a manner which rapidly made him an outstanding authority in his field. Plans for the rehabilitation of oyster beds which arose from this work resulted in the establishment in 1953 of a new fishery laboratory at Burnham-on-Crouch largely devoted to this purpose. Dr. Cole succeeded the late Mr. R. E. Savage at this juncture as head of the Shellfish Section, with his headquarters at the new laboratory. From here he and his staff produced much valuable advice on the cleansing and rearing of shellfish and initiated a considerable amount of development work on culture and pest control. In addition to this Dr. Cole found it possible to foster a substantial amount of new research work. This included, besides the nanoplankton food of the larval oyster, investigations into the natural history and exploitability of cockles, clams, whelks, scallops, shrimps, crabs and lobsters. When the International Council for the Exploration of the Sea founded its Shellfish Committee Dr. Cole was appointed the English representative. For the past three years he has served as the chairman of this body, effecting a useful integration of the several national programmes and working successfully towards standardization of methods. In 1954 he was offered the Buckland Professorship, choosing for his series of lectures the title "Inshore Fisheries", and in February 1958 he was appointed deputy director of fisheries research.

Mr. R. J. H. Beverton

Mr. R. J. H. Beverton, who succeeds Dr. H. A. Cole as deputy director of fisheries research in the Ministry of Agriculture, Fisheries and Food, joined the Fisheries Laboratory, Lowestoft, as a scientific officer in 1945. Having taken a first in zoology in Part 2 of the Natural Sciences Tripos at Cambridge and the Frank Smart Prize as best student of the year, he devoted a good knowledge of mathematics and his sympathy for this subject to considering a mathematical formulation of fish stocks under the influence of fishing. Working in the Population Section under Mr. Michael Graham he quickly developed the subject, and in conjunction with Mr. S. J. Holt, now of the Food and Agriculture Organization, has produced a manual on the subject of population dynamics of fish species which is a classic and which has made him a world authority in this field. During the past ten years he has produced numerous papers and memoranda and his advice, offered directly or indirectly to international bodies such as the Permanent Commission of the 1946 Fisheries Convention, the International Council for the Exploration of the Sea, and the International Commission for the Northwest Atlantic Fisheries, has made his position as an adviser on fisheries conservation quite outstanding. In addition to this he has twice been called on to visit and report on the fisheries of the Colonial dependencies; in the first instance Lake Victoria Nyanza and in the second the sea fisheries of the Kenya and Tanganyika coasts. He has also been twice invited abroad to give a course of lectures on his subject, once in the United States and once in Canada. Mr. Beverton succeeded Mr. Michael Graham as head of the Population Section at Lowestoft when the latter retired in February last year. In addition to the very considerable volume of direct research work on which he is engaged, Mr. Beverton has been responsible for developing the collection of research statistics and fish measurements at the ports on a scale that has not been equalled elsewhere.

Kalinga Prize : Prof. Karl von Frisch

Prof. Karl von Frisch, of Munich, the eminent zoologist, well known for his research on the sensorial physiology of insects and fish, has been awarded the Kalinga Prize for popularization of science. The prize of £1,000 is offered annually by the Kalinga Foundation, which has been set up to contribute to the economic, social and cultural progress of the Indian State of Orissa. The purpose of the award, as stated by Mr. B. Patnaik, its donor, is to offer recognition to leading interpreters of science and also to strengthen links between India and scientists of all nations.

Space Research in Britain

Following the Prime Minister's statement on the British space research programme, in the House of Commons on May 12, the Lord President of the Council has appointed a Steering Group on Space Research, under the chairmanship of Sir Edward Bullard, with the following terms of reference: "Subject to the responsibility of the Lord President of the Council, in consultation with the other Ministers concerned, for the supervision of the Government's Space Research Programme, to advise on the formulation of that programme, and to co-ordinate the arrangements for its execution".

The membership of the Group is as follows: Sir Edward Bullard (*chairman*); Prof. W. V. D. Hodge, secretary of the Royal Society; Prof. H. S. W. Massey, University College, London; Sir Harry Melville, secretary, the Department of Scientific and Industrial Research; Sir Graham Sutton, director-general of the Meteorological Office; Dr. R. van der R. Woolley, Astronomer Royal; and senior officials representing other interested government departments. The Steering Group had its first meeting on May 27.

Space Monkeys

On May 28 two monkeys were recovered unhurt from the nose cone of an American Jupiter missile after a space-flight of 1,500 miles. The flight lasted about 15 min.; the missile reached an altitude of about 300 miles and attained speeds of up to 10,000 m.p.h. During the flight reports of the monkeys' heartbeats, muscular reactions, pulse, temperature and respiration were, among other things, relayed back to Earth. The animals seem to have been little affected by the violent acceleration and the 9-min. period of weightlessness which they experienced. They will probably appear on television. The nose cone also carried samples of yeast, corn, mustard seed and fruit-fly larvæ, and, in order to study the effect of weightlessness on the processes of fertilization, phials of the eggs and sperm of sea-urchins which were mixed when the missile attained its maximum velocity.

Department of Scientific and Industrial Research Committee on Metal Fatigue

A committee to review current research needs on the fatigue of engineering structures and to survey existing research facilities has been set up by the Council for Scientific and Industrial Research following an approach from the Institution of Civil Engineers. The committee will not include aircraft structures, reinforced concrete structures, or metal physics in the scope of its review, though information gained in these fields will be used. Sir Alfred Pugsley (University of Bristol) has been appointed chairman. The other members of the committee are: Sir Donald G. Bailey, Mr. T. Baldwin, Mr. H. L. Cox, Mr. O. A. Kerensky, Mr. H. M. Pemberton, Mr. C. E. Phillips, Prof. S. C. Redshaw, Dr. P. B. Walker and Dr. R. Weck. The committee's terms of reference are: "to review current research needs on fatigue of engineering structures (metal), to survey existing research facilities and to make recommendations to the Department of Scientific and Industrial Research". The committee is interested in examining records of failures or accidents which might have been due to structural fatigue, even if fatigue was not recognized as the initial cause. Such information may be helpful in revealing areas in which further research work is needed.

Regional Technical Information Services

In reply to a question in the House of Commons on May 12, Mr. H. Nicholls, Parliamentary Secretary to the Ministry of Works, as representing the Lord President of the Council, said that the Department of Scientific and Industrial Research was helping active local organizations to build up regional technical information services based on Birmingham, Bristol, Cardiff, Manchester and Newcastle-upon-Tyne, and the staffs of these centres put firms in touch with sources of information. The contact was made by actual visits from the research centres and by the normal Press reports and brochures. In answer to another question, Mr. Nicholls said that from the research reports on social and psychological research in industry, the Department, with the agreement of the Medical Research Council, had selected twelve projects as suitable for presentation in a short and popular form, and three of these had already been published by H.M. Stationery Office.

International Cultural Affairs

In a debate on the international situation in the House of Lords on May 4, Lord Aberdare stressed the value of university scholarships and exchanges in furthering international understanding, and urged the Government to consider increasing its present grant of £6,000 a year to the European Cultural Fund which at present has an income of only £32,000 a year. Lord Lansdowne, in replying for the Government on the debate, made no comment on this proposal, which was also advanced in an adjournment debate in the House of Commons on May 1. In the House of Commons, Mr. R. Allan, the joint Under-Secretary of State for Foreign Affairs, said that the Government was playing its part in the cultural work of the Council of Europe and was anxious to take it further. It did not exclude the possibility of a further voluntary government contribution, but wished to see first what could be done from private sources, as had been suggested by Mr. H. Delargy and Mr. R. Russell in opening the debate.

Beit Memorial Fellowships

The Trustees of the Beit Memorial Fellowships for Medical Research in their report for 1958–59 announce that Sir Francis Glyn has been elected a Trustee and honorary treasurer of the Trust; that Dr. Honor B. Fell has been appointed to the Advisory Board in place of Prof. J. H. Gaddum, who retires after fifteen years service; and that Sir Roy Cameron has been appointed secretary of the Trust in place of Prof. A. A. Miles, who retires from the secretaryship after seven years service.

The following elections have been made.

Junior Fellowships. Dr. W. D. Stein, to study the mechanism of specific transport systems across cell membranes at the molecular level, with special reference to the components concerned in the movement of glycerol across the human red blood cell membranes; at the Department of Colloid Science, University of Cambridge. Dr. G. Burnstock, to study the action of drugs on smooth muscle and the effect of autonomic nerve stimulation on the membrane potential recorded from smooth muscle cells; at the Department of Pharmacology, University of Oxford. G. L. Asherson, to study the causation of rheumatoid arthritis, systemic lupus erythematosus and other diseases in which antibodies against human and animal tissue can be detected; at the Rheumatism Research Unit (Medical Research Council), Canadian Red Cross Memorial Hospital, Taplow. E. R. Huehns, to study the hæmoglobins and the non-hæm proteins in normal and abnormal human red blood cells, with the view of distinguishing thalassæmia from the hæmoglobinopathies; at the Department of Biochemistry, University College, London. C. T. G. Flear, to study sodium–potassium exchange in tissues during induced congestive heart failure, and its bearing on the therapy of congestive heart failure in man; at the Department of Experimental Medicine, University of Cambridge.

Fourth Year Fellowships. T. F. Slater, to continue the study of the enzymic constitution of the rat mammary gland in relation to lactation; at the Department of Biochemistry, University College, London. Dr. J. R. Tata, to continue the study of normal and abnormal pathways of metabolism of thyroid hormones; at the National Institute for Medical Research, Mill Hill, London.

Presenting Science to the Public

An article by Prof. P. M. S. Blackett, reprinted from *Progress* of May 1958, appears under the title "The British Association Looks Ahead" together with two short notes on presenting science to the public in *The Advancement of Science* for March 1959. Prof. Blackett, starting with a brief historical survey, indicates some of the ways in which the British Association is seeking to play a wider part in the interpretation of science to the nation, and the three main aspects of modern science with which the Association must concern itself in so doing. The following note describes the work of the three area committees established at Newcastle, Durham and on Teeside, the lecture service, particularly for school audiences, the educational programme for young people under sixteen and the rapid development of the work of the Metric Committee and of the study group on the education of the graduate scientist in schools and universities. The third note describes the progress made in the preliminary survey of existing visual aids in relation to the Young People's Programme requested by the Visual Aids Committee in November 1958. The Young People's Programme is based on three main assumptions: that the most effective single weapon would be a magazine designed to present science attractively and authentically to young people; that it is also necessary to give the schools all possible help; and that the Science Clubs will require all possible assistance, including visual aids. It is believed that the Association would perform a major service by providing an impartial survey which outlined the role of existing agencies, published comments by those working in the field on the use and suitability of existing aids; and recommended, after consultation with existing agencies and individual experts, action to promote the better use of the material available as well as the production of new material.

Lecture Theatre proposed for the Royal Aeronautical Society

The Hyde Park Corner reconstruction scheme has provided the Royal Aeronautical Society with a unique opportunity for building a much needed lecture theatre at the back of its headquarters at

4 Hamilton Place, London, W.1. The new Apsley carriageway cutting across the corner of the Park is to be started soon and will give access to the site, but only while the road is under construction. The Society has seized this chance to launch an immediate appeal for the £150,000 needed to build and furnish a theatre seating more than 300. The detailed plans are completed and open to inspection. All planning permissions are assured and it is hoped to start work this September. Donations should be sent to the Secretary of the Society at the above address.

Ultrasonic Vibrations at 10,000 megacycles

An announcement by the International General Electric Co., of New York, reports that one of its scientists, Dr. E. H. Jackson, has been able to produce ultrasonics at the enormous frequency of 10,000 megacycles per second. Up to the present, the limit of frequency has been about 200 megacycles per second, obtained from one of the high harmonics of a thin slice of quartz, excited piezoelectrically. Details of Dr. Jackson's method are not given, but it appears that a quartz crystal is combined with a cavity resonator in such a way as to excite it at a high frequency. The usual difficulty with such a device is to avoid the crystal jumping from one harmonic to another, but to prevent the ultrasonic energy degenerating into that associated with thermal vibrations in the material, the crystal is kept at 2° K. It is proposed to use the source to investigate the energy-level of atoms and the interactions of electron spins in a crystal lattice. Another useful application—if the vibrations can be kept 'pure'—should be to study the absorption and velocity of ultrasonics in fluids with the view of finding very short relaxation times in the transfer of energy between the degrees of freedom of the molecules.

South African Museum

The success of a museum as an educational centre is to a large extent dependent on a competent professional staff. The report of the South African Museum for 1957–58 (pp. 19. Cape Town: South African Museum, 1958) indicates that three posts for professional officers and a taxidermist which had been allowed to lapse have been revived and a new post of historian established. It is hoped that the creation of the latter post will lead to the formation of a Cultural-historic Museum in Cape Town. A new store has been built and the Museum is now in a position to accept historical material for safe keeping and subsequent exhibition. Unfortunately the staff are so fully occupied with normal curatorial work that they have little time for research, a function which is essential for the full development of a museum. The report includes notes on five new inscribed stones recently discovered on the site formerly occupied by the General Post Office in Cape Town.

A New Field Centre

The Field Studies Council is planning to open a sixth Field Centre during 1959. In co-operation with the Herbert Whitley Trust, a building and land are being acquired at Slapton in South Devon, and, in the first place, it is hoped to provide facilities for about thirty students. The Council has designated Mr. Ian Mercer, formerly assistant warden at Juniper Hall Field Centre, to the warden's post at the new centre. The property is situated at the seaward end of Slapton village about 400 yd. from the shingle of Start Bay. Behind the shingle bank are two large freshwater lakes—the Leys—which, together with Slapton Wood and France Wood, constitute a Nature Reserve which will be leased to the Field Studies Council by the Herbert Whitley Trust. There is considerable opportunity for biological fieldwork. It is hoped that the Centre can be opened for small parties in the near future and more fully from July 1, 1959.

Besides the new Centre, the annual report for 1957–58 (pp. 28 + 4 plates. London: Field Studies Council, 1959) describes the continued growth and public demand for the existing Centres. Unlike previous issues, the annual report contains no scientific papers. In future, these are to be published independently under the new title, *Field Studies*. The first issue will include papers on the mollusca of the Flatford area; the insects of the Malham area; the geography of the Alberbury breccia; and the geomorphology of the Tillingbourne.

Architectural Science Review

Building is one of the traditional occupations of mankind which has become the subject of organized scientific inquiry only in comparatively recent times. In the early stages of research on building, attention was concentrated on the materials and constructions used, but latterly increased attention has been given to the overall problems of design. It is precisely with the scientific basis of architecture in the narrow sense of design for function that the new Australian journal, *Architectural Science Review*, is concerned (**1**, No. 1. Pp. 56. Three issues per year. Annual subscription, post free, 42*s*. (Australian); single copies, 15*s*. Academic Press Proprietary, Ltd., Sydney, Australia). The general scope of the *Review* is illustrated by the papers in the first issue and by the titles proposed for the second. In the first issue there are papers concerned with thermal comfort zones, the weathering of buildings (with particular reference to curtain walls), the design of structures with the aid of models, building in the tropics, and daylighting design. In addition, a selective bibliography on climate and architecture is given. For the second issue, papers on the Australian climate, on lifts and escalators, and on high-alumina cements are proposed, in addition to two further papers on lighting and insolation. The *Review* promises to provide a focus for the publication of researches which at present are scattered in numerous scientific and architectural journals. A new journal covering the field is to be welcomed, and it may well attract papers from outside Australia.

Kanamycin

The New York Academy of Sciences has recently published, in the form of a monograph, laboratory and clinical results obtained with kanamycin in various centres in North and Central America (*Ann. N.Y. Acad. Sci.*, **76**, 11; 1958. Article 2: The Basic and Clinical Research of the New Antibiotic, Kanamycin. By Maxwell Finland and 93 other authors. Pp. 17–408). Kanamycin is yet another *Streptomyces* antibiotic, which was discovered by H. Umezawa and co-workers of Tokyo. Obtained from a new species *Streptomyces kanamyceticus*, kanamycin is basic and water-soluble, closely related chemically to neomycin and has some features in common with streptomycin; it consists of two amino-sugars linked glucosidally to 2-deoxystreptamine.

In vitro, kanamycin is active against many common pathogenic aerobic Gram-positive and Gram-negative bacteria and *Mycobacteria*, but some *Pneumococci*, most *Streptococci* and *Pseudomonas* are resistant. Anaerobic organisms, yeasts and fungi nearly all show high resistance. Resistance to kanamycin induced in *Staphylococci* and in *E. coli* is accompanied by complete cross-resistance to neomycin and paromomycin and by partial cross-resistance to streptomycin, but no cross-resistance to unrelated antibiotics. Clinical results show that, given intramuscularly, the drug is effective in staphylococcal infections, gonorrhea, anthrax, and in many infections of the urinary tract, particularly when resistant to other antibiotics. Given orally, it inhibits aerobic intestinal bacteria. Alone, it is of doubtful value in tuberculosis, but is claimed to have some effect with *p*-aminosalicylic acid. The major toxic effects are on the kidney and eighth cranial nerve, but the renal toxicity is less marked than that of neomycin and the adverse vestibular and auditory effects are less than those obtained with streptomycin.

The Royal Institution : Officers

At the annual meeting of the Royal Institution, held on May 1, the following officers were elected : *President*, Lord Brabazon of Tara ; *Treasurer*, Mr. W. E. Schall ; *Secretary*, Sir Harold Spencer Jones ; *Managers*, Dr. T. E. Allibone, Dr. H. D. Anthony, Mr. F. G. Brown, Dr. A. G. Gaydon, Prof. A. Haddow, Mrs. H. K. Hawkes, Dr. H. Heywood, Dr. R. Holroyd, Mr. E. Ironmonger, Prof. L. A. Jordan, Mr. J. Lawrie, Sir Ben Lockspeiser, Mr. J. A. Oriel, Mr. H. P. Rooksby, and Mr. P. H. Schwarzschild ; *Visitors*, Mr. A. D. Baynes-Cope, Prof. H. Dingle, Dr. D. H. Follett, Mr. A. J. Haselfoot, Mr. S. Rees Jones, Mr. W. C. Lister, Miss C. M. McDowell, Mrs. J. E. Milton, Mr. F. A. Mitchell, Mr. N. P. W. Moore, Mr. J. D. Peattie, Mr. F. Y. Poynton, Mr. N. Shepherd, Dr. P. C. Spensley, and Dr. N. Stuart.

University News : Birmingham

The Council of the University, subject to the concurrence of the Senate, has gratefully accepted the offer of a contribution of approximately £140,000 spread over seven years for the purpose of enlarging and developing the Graduate School of Highway and Traffic Engineering, and for the establishment of a chair in the subject. The offer is made by a number of bodies concerned with road development, including the motor industry, oil companies, civil and engineering and surfacing contractors, insurance firms and motoring organizations.

The Nuffield Foundation has made a grant of £12,000 to the University, spread over five years from May 1, 1959, towards the cost of an investigation to be carried out in the Research Department of the Institute of Education into the placing, counselling and teaching of part-time students in a local technical college. The research will be under the direction of Mrs. E. C. Venables, at present part-time research fellow in the Institute of Education.

The following have been promoted to senior lectureships from October 1 : Dr. J. G. Valatin (mathematical physics), Dr. G. W. Greenlees (physics), Mr. R. H. Knight (physics), Dr. D. H. Whiffen (chemistry), Dr. V. G. Welsby (electrical engineering), Dr. V. Kondic (industrial metallurgy), Mr. P. T. Geach (philosophy), Dr. J. B. Finean (medical biochemistry and pharmacology). The following appointments have also been made : Dr. H. B. van der Raay, to be lecturer in physics ; Dr. R. W. Smith, to be lecturer in physical metallurgy ; and J. A. Nelder, head of the Statistics Section of the National Vegetable Research Station at Wellesbourne, to be a recognized lecturer in the Department of Pure Mathematics.

London

The following have been appointed to readerships tenable at the Imperial College of Science and Technology : Dr. F. G. H. Blyth (engineering geology) ; Dr. E. H. Brown (structural analysis) ; Dr. J. Edelman (enzymology) ; Dr. S. Eilon (production engineering).

Announcements

Under the statute of the Royal Society which provides for the election of persons who either have rendered conspicuous service to the cause of science or are such that their election would be of signal benefit to the Society, H.M. King Gustaf VI Adolf of Sweden has been elected a Fellow of the Royal Society.

The charter of the Middle East Technical University, Ankara, has been approved by the Grand National Assembly of Turkey. The conception of the University, which is intended to be an international centre of higher learning, was described in *Nature* of February 8, 1958, p. 382.

A symposium, arranged by the International Commission for Optics, in connexion with its fifth congress on Modern Systems for Detecting and Evaluating Optical Radiation, will be held in Stockholm during August 24–30. Further information can be obtained from Prof. E. Ingelstam, International Commission for Optics, Stockholm 70.

The summer meeting of the Science Masters' Association will be held in the Science Laboratories of the Durham Colleges during July 27–31. In addition to the usual programme of meetings and visits, there will be Publishers', Manufacturers' and Members' Exhibitions, and a discussion on "General Trends in Science Teaching in the Universities of the Commonwealth", introduced by Prof. W. B. Fisher. Further details can be obtained from the Meeting Secretary, W. H. Dowland, 93 Westbourne Road, West Hartlepool, Co. Durham.

Under the auspices of the International Union of Biochemistry, a symposium on Hæmatin Enzymes is to be held in Canberra, Australia, during August 31–September 4. The symposium is being arranged by the Australian Academy of Science, and participation is by invitation. The proceedings of the symposium are to be published by the Pergamon Press in a special volume. Further information can be obtained from Prof. R. K. Morton, Department of Agricultural Chemistry, University of Adelaide, South Australia.

An International Conference on Nuclear Structure will be held at Queen's University, Kingston, Ontario, during August 29–September 3, 1960. The conference, in addition to receiving support from the International Union of Pure and Applied Physics, will be sponsored in Canada jointly by Atomic Energy of Canada, Ltd., and Queen's University. The secretary of the conference is Dr. L. G. Elliott, Atomic Energy of Canada, Chalk River, Ontario, to whom further inquiries can be directed.

Erratum. In the article "A New Short-acting Thiobarbiturate", by Dr. M. E. Peel *et al.*, published in *Nature* of May 23, p. 1443, in Table 1 for compound B.137, R' should read Bu^{s}, not Bu^{i}.

DEPARTMENT OF HUMAN ANATOMY, OXFORD: NEW BUILDINGS

THE time devoted by medical students to the meticulous dissection of cadavers and the memorizing of a mass of anatomical detail has diminished considerably in Great Britain during the past half-century. It is now recognized that an encyclopædic knowledge of topographical anatomy is devoid of educational value and its practical application is restricted to surgical specialists and a few selected research workers. By contrast, a knowledge of the structure and functional role of the tissues which go to make up the body in subjects of all ages, of their reactions to stress, and to the wear and tear of everyday life, is acknowledged to be of both educational and practical value to physicians, surgeons, general practitioners and research workers alike.

This re-orientation in the role of anatomy as an academic discipline in Britain owes more to Sir Wilfrid le Gros Clark than to any other anatomist. F. P. Mall pioneered a similar movement at Johns Hopkins University in the United States of America in the early 1900's which was quickly accepted and exploited by such eminent scientists as George Corner, Herbert Evans and George Wislocki. Now, however, there is a tendency in the United States to regard anatomy as a part of biology almost divorced from medicine, and to appoint more and more teachers who have not had a medical training. The opening of the new Department of Anatomy in the University of Oxford (Fig. 1) is a milestone in the history of a reformation in England which has proceeded more slowly and which seeks to avoid this tendency.

Sir Wilfrid's genius has been to gather around him, and provide facilities for, people interested primarily in the changes which occur in the tissues of the human body in health and in response to trauma (and selected diseases) from conception to death from old age. This is not to say that experimental work on lower animals is not carried out in his Department; indeed, it is, but that, under his leadership, teaching and research are directed more towards the biology of man than of other animals. Sir Wilfrid has contrived to allow anatomy to evolve rather than denying it a place as an academic discipline or allowing it to become a home of lost biological causes. This he has achieved through his unique distinction both as an outstanding experimental neurologist and as an outstanding authority on primate anthropology which, incidentally, he regards as a hobby.

The subjects most strongly represented in the new Department are neuroanatomy, with special reference to vision, olfaction and common sensation. Modern methods of microscopy, including electron, reflecting, phase contrast and interference techniques, are also

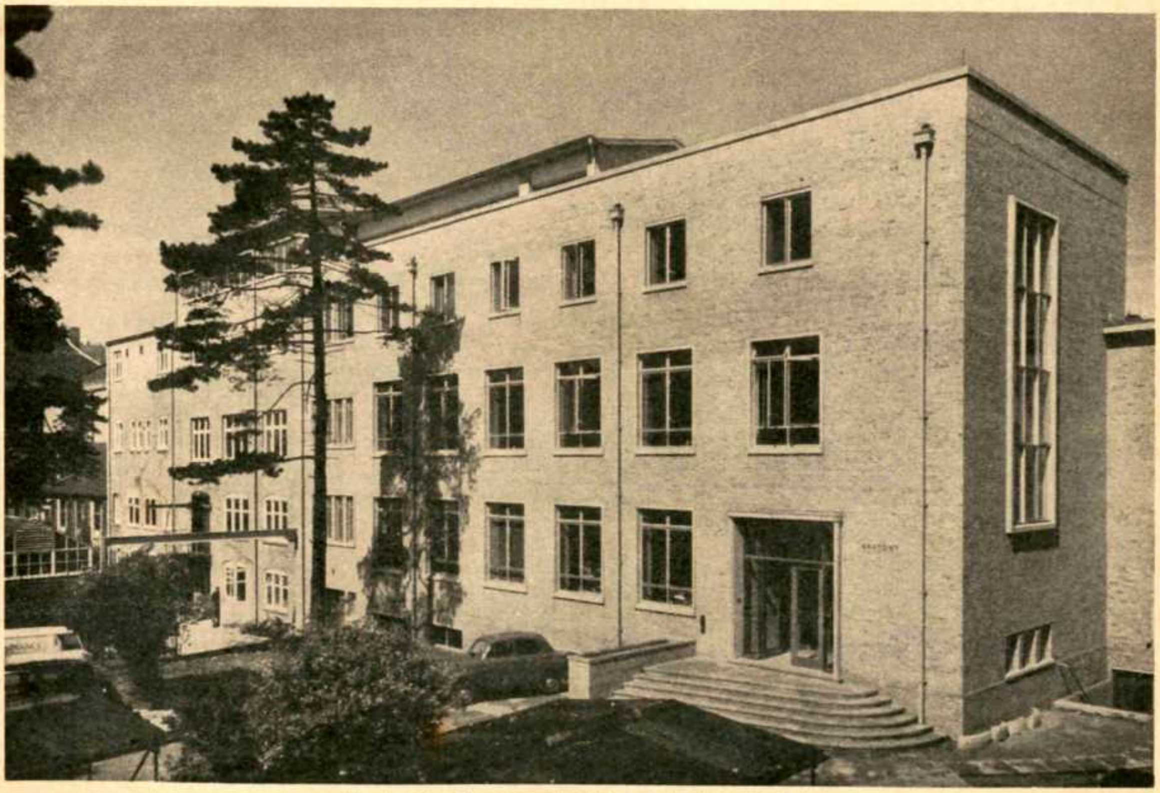

Fig. 1. New Department of Human Anatomy, Oxford

under active investigation. They are housed in special rooms in the basement of the building and are being used, among other things, to obtain quantitative data concerning the anatomy of individual living cells. The mechanics of muscular activity in man and in experimental animals are also being studied by a number of different methods, including strain gauge techniques and electromyography. Physical anthropology is also strongly represented and intensive work is being carried out on the adaptation of human subjects of different age and race to extremes of environmental temperature.

The old department has been entirely transformed from a mushroom growth of ill-suited, over-crowded research rooms, leading off from an old-fashioned dissecting room and a small museum, to a modern research laboratory adaptable to any field of biological study.

The essential features of the new Department are an extremely well lit, adequately ventilated and conveniently proportioned dissecting room. This can also be used for the study of surface and functional anatomy. It surmounts a large, well-equipped histological laboratory which in turn surmounts a basement containing an up-to-date embalming room, body store, and a room in which recently deceased persons can be viewed by relatives should the necessity arise. Close to this unit are a conventional lecture theatre, a small demonstration theatre and a departmental library. Beyond these is a commodious museum which can also be used as a study and reading room. This has evolved from the former dissecting room by a process of adaptation and the skilful use of modern methods to improve the interior décor of the old structure. Lying between the museum and the new dissecting room are the laboratories and offices occupied by the staff.

The staff includes a professor, two readers and four University demonstrators, each of whom devotes his time to a particular branch of anatomy, assisted by departmental demonstrators and postgraduate students reading for higher degrees. A few rooms which serve as combined laboratories and offices have been set aside for the use of temporary visitors from overseas. Housed and integrated with the rest of the Department is a Medical Research Council climatic and working efficiency unit which possesses an up-to-date climatic chamber. The Department also has a large well-equipped workshop for handling metal, plastics and wood, as well as a smaller instrument workshop. It also contains a large well-designed photographic department containing the most modern equipment which is capable of handling every kind of photographic problem. The animal house and operating theatre are on the roof of the building and conform to the highest modern standards. The individual research laboratories are simple yet quickly adaptable to different kinds of biological research with the minimum of expense. In particular, they are well lit and ventilated, and provided with a service panel encircling the room, having gas, electrical (direct and alternating current) and compressed-air outlets at intervals. The rooms are also provided with sinks having hot and cold water supplies. Three of the rooms contain, in addition, fume cupboards, and two rooms have voltage-stabilized alternating-current electrical outlets and dark-room blackout blinds. There is also a small light- and sound-proof room. The majority of the benches in these rooms are movable but strong, rigid, relatively light and fitted with plastic tops. They have been supplied in two standard heights, lengths and widths, and they can be fitted adjacent to the walls beneath the service panel. They can thus be moved from room to room according to requirements. A variety of units in two sizes containing drawers and/or cupboards have been provided for fitting beneath the benches. These can also be moved from room to room to suit particular requirements. These research rooms can therefore be adapted to serve such diverse techniques as standard histology, tissue culture, biochemistry and biophysics. An adequate number of lavatories, wash basins, locker and store rooms have also been provided.

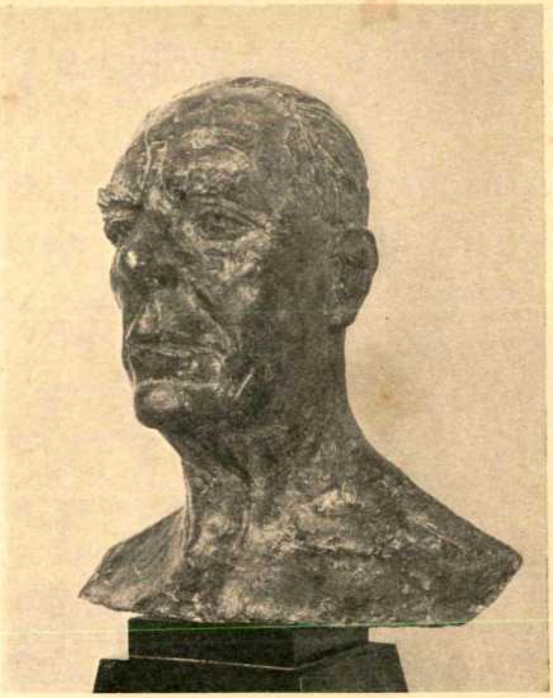

Fig. 2. Bust by Sir Jacob Epstein of Sir Wilfrid le Gros Clark

Sir Wilfrid's friends and colleagues have recognized that his genius has set him among the immortals. But as the regius professor of medicine at Oxford, Sir George Pickering, said when he opened the new building on March 16: "Immortality as is commonly conceived is relative rather than absolute and, since what is generously called the growth of scientific literature, may obscure masterpieces like le Gros Clark's writing, his friends thought it right to secure his more permanent immortality by asking Sir Jacob Epstein to create a portrait bust". The opening of the new Department comes just twenty-five years after Sir Wilfrid was appointed Dr. Lee's professor of anatomy and Fellow of Hertford College in the University of Oxford. It is therefore very fitting that a work of this kind should have been commissioned from a great sculptor in honour of Sir Wilfrid, to be permanently housed in the Department which his vision has done so much to create.

The bronze portrait bust of Sir Wilfrid le Gros Clark is sited in the entrance hall of the new building in a quiet and dignified setting but where it can be seen and examined for the work of art which it is (Fig. 2).

U.S. NATIONAL ACADEMY OF SCIENCES

Centennial Gift from the Equitable Life Assurance Society

THE U.S. National Academy of Sciences, the president of which is Dr. Detlev Bronk, is to receive a gift of a million dollars from the Equitable Life Assurance Society of the United States as a contribution to the nation's welfare during the Society's hundredth anniversary. The Academy itself celebrates its centennial in 1963.

The gift will provide for the erection of a Hall of the Life Sciences, in which will be housed the many scientific activities of the Academy and its National Research Council in the fields of biology and medicine.

The National Academy of Sciences is a private, non-profit organization electing its own members from among leading scientists of the United States. The Academy was established in 1863, under a Congressional Charter signed by President Lincoln, to advance science, further human welfare and advise the Federal Government on scientific and technical matters.

The National Research Council was organized by the Academy in 1916 at the request of President Woodrow Wilson, as a part of the Academy, in order to enable representatives of the major scientific and technical societies to co-operate in the efforts of the Academy in the service of science and the national welfare.

The Academy–Research Council is the principal agency through which American scientists participate in co-operative international scientific undertakings such as the International Geophysical Year and other activities of the international scientific unions.

The present building of the National Academy–Research Council, which is generally considered to be one of the most beautiful in Washington, was constructed in 1924 with funds provided by the Carnegie Corporation of New York and was dedicated thirty-five years ago by President Coolidge. It is situated on Constitution Avenue, adjacent to the New State Department Building now under construction, and facing the memorial to Abraham Lincoln, who was the founder of the Academy.

Architects for the new Hall will be Harrison and Abramovitz, who have been associated with the design of many of the notable buildings of America, such as the Rockefeller Center, the Lincoln Square project in New York, and the United Nations building.

Dr. Bronk made the following comment on the Equitable gift: "Erection of this new Hall of the Academy to house the medical and life sciences will be of great value to our nation. It is eminently appropriate that the Equitable Life Assurance Society thus contribute to the work of the Academy, for we are both private organizations devoted to the public welfare.

"Both organizations are deeply concerned with the furtherance of those sciences which prolong life and increase health. We are both national in scope. In the beautiful centre of our national capital, the Hall of the building provided by the Equitable centennial gift will symbolize your service to the welfare of the people of our nation and will enable us to increase our service as we, too, begin our second century".

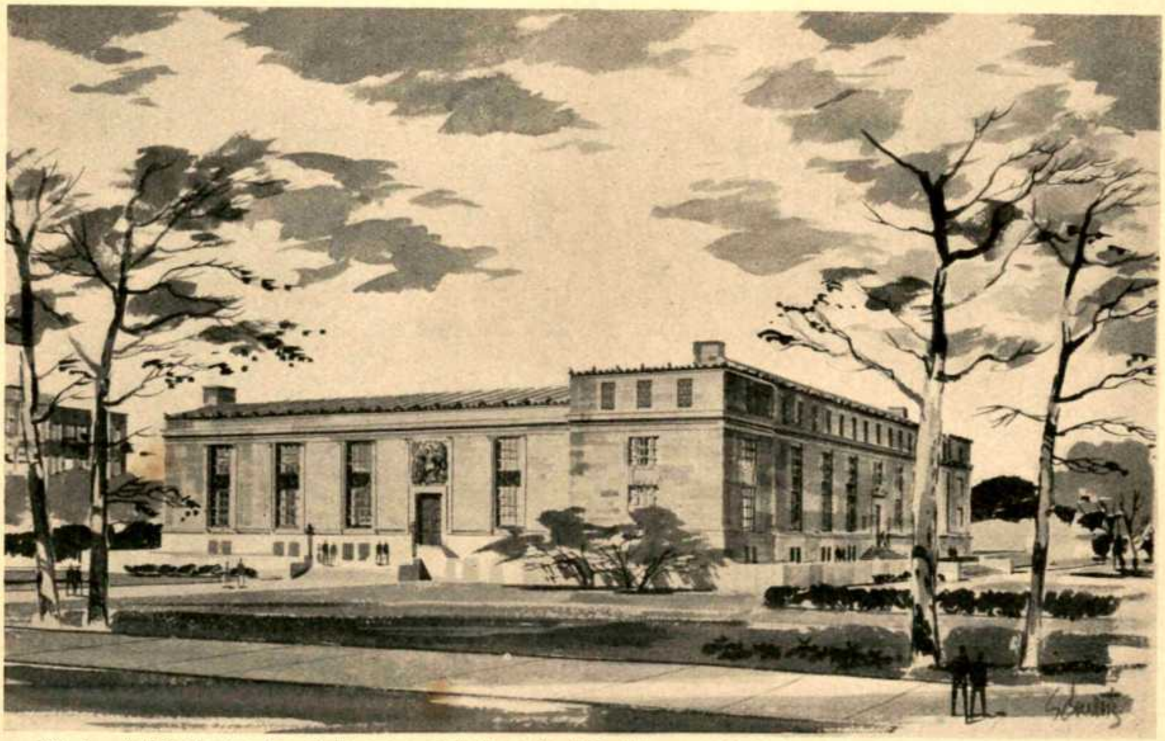

Fig. 1. Architect's drawing of the proposed Hall of the Life Sciences, U.S. National Academy of Sciences, provided by the Equitable Life Assurance Society

When the Academy's building was erected in 1924, it was planned to accommodate additional wings as the need developed and funds became available. With the greatly increased scope of the Academy's work, more space has been urgently needed, and many activities of the Academy–Research Council have had to be housed in widely scattered locations throughout Washington.

The work of the Academy–Research Council is carried on by more than a thousand committees comprising scientists who voluntarily give their time and represent all fields of science; they are served by a full-time staff of more than 1,100. More than 10,000,000 dollars a year is provided for the work of the Academy by private foundations, contracts and grants from the Federal Government, and income from the Academy endowment of approximately 7,000,000 dollars a year.

Elections

Dr. Hugh L. Dryden, deputy administrator of the National Aeronautics and Space Administration, has been elected to a second four-year term as home secretary of the U.S. National Academy of Sciences.

Dr. Roger Adams, research professor of chemistry, University of Illinois, and Dr. William V. Houston, president of Rice Institute, have been elected members of the Council. The two councillors who are retiring are Dr. I. I. Rabi, professor of physics, Columbia University, and Dr. F. E. Terman, professor of electric engineering, Stanford University.

As members of the Council of the Academy, the home secretary and the two new councillors will share responsibility for the general conduct of the Academy and its National Research Council.

The following have been elected to membership of the Academy:

Dr. Philip H. Abelson, director of the Geophysical Laboratory, Department of Terrestrial Magnetism, Carnegie Institution of Washington.

Prof. Walker Bleakney, Brackett research professor in Princeton University.

Prof. David Bonner, professor of microbiology, Yale University.

Prof. Tom Bonner, professor of physics, Rice Institute.

Dr. Walter Brattain, research physicist, Bell Telephone Laboratories (on leave with the National Defense Research Committee, Columbia University).

Prof. Leo Brewer, professor of chemistry, University of California at Berkeley.

Prof. Frank Brink, dean of graduate studies, Rockefeller Institute.

Prof. Jens C. Clausen, Division of Plant Biology, Carnegie Institution of Washington, and professor of biology, Stanford University.

Prof. Samuel Eilenberg, professor of mathematics, Columbia University.

Prof. John D. Ferry, professor of chemistry, University of Wisconsin.

Prof. Kurt O. Friedrichs, professor of applied mathematics, New York University.

Prof. Hiram B. Glass, professor of biology, Johns Hopkins University.

Prof. M. J. Herskovits, professor of anthropology, Northwestern University; former visiting professor, Graduate School, University of Illinois.

Prof. Herman M. Kalckar, professor of biochemistry, Johns Hopkins University.

Prof. Konrad B. Krauskopf, professor of geology, Stanford University, and geologist, U.S. Geological Survey.

Prof. I. Michael Lerner, professor of genetics, University of California at Berkeley.

Dr. Rudolph L. B. Minkowski, Mount Wilson and Palomar Observatories, and research associate, California Institute of Technology.

Dr. Harry F. Olson, Radio Corporation of America Laboratories.

Prof. C. Pfaffmann, professor of psychology, Brown University.

Prof. Richard J. Russell, professor of physical geography, and dean of the Graduate School, Louisiana State University.

Prof. John A. Simpson, scientific consultant, Argonne National Laboratory.

Prof. Dean S. Tarbell, professor of organic chemistry, University of Rochester.

Prof. Henry Taube, professor of chemistry, University of Chicago.

Prof. James A. Van Allen, professor of physics, State University of Iowa.

Prof. Cecil J. Watson, professor of medicine, University of Minnesota.

Prof. Gregor Wentzel, professor of physics, University of Chicago.

Prof. Fred L. Whipple, director, Smithsonian Astrophysical Observatory (a close associate with Harvard College Observatory).

Prof. William B. Wood, jun., vice-president of medical affairs, and professor-elect of microbiology, Johns Hopkins University.

Prof. Clarence M. Zener, director, Westinghouse Research Laboratories.

Dr. Raymond E. Zirkle, professor of radiobiology, University of Chicago.

CHARACTERISTICS OF THE ANTARCTIC ICE-SHEET

THE Royal Astronomical Society Geophysical Discussion of February 27 was held jointly, in the Society's rooms at Burlington House, with the British Glaciological Society. This combining of interests by the two organizations was matched by the bringing together of the theoretical with the directly practical interests, for the main speakers were Dr. J. F. Nye (chairman) on one hand, and M. B. Imbert, Mr. J. G. D. Pratt and Dr. H. Lister on the other. Dr. Nye's important contributions to the study of ice-sheets are well known and, perhaps more than anyone, he has shown clearly what physical properties should be measured by the expeditions that go to make the necessarily difficult and sometimes hazardous experiments; and he has put together the numbers of the problem so that the field men can plan their experiments and know when they are getting a reasonable answer.

M. Imbert has for many years been principal assistant to Dr. Paul Emile Victor of the Expéditions

Polaires Françaises, and Mr. Pratt is a seismologist of world-wide experience in the British Petroleum organization. They both had returned recently from Antarctica and were able to describe some of their results, both seismic and gravitational, fresh from the detailed analysis that awaited their return home. As opposed to the static problem of what is there now, Dr. Lister studies the mechanism of deposition of snow and its formation into an ice-sheet, together with the dynamical aspects and the history of these phenomena. Dr. Lister and Mr. Pratt were members of Sir Vivian Fuchs's Commonwealth Trans-Antarctic Expedition, and M. Imbert was leader of the French team in Antarctica for the International Geophysical Year.

Dr. Nye explained that the behaviour of an ice-sheet is governed by two opposing forces: the weight, which tends to squeeze the ice out sideways, and the resistance to outward flow provided by the bed. These two forces are essentially in balance.

The properties of the ice depend upon the temperature distribution in the ice, and this in turn is affected by two main sources of heat. Heat is flowing from the Earth itself, presumably in the absence of volcanic activity, at the normal rate, and it is also developed by friction as the ice moves over the rock bed. If the effects of transverse convection are ignored, theory suggests that both sources of heat are tending to make the lower layers of ice warmer than the upper ones. The ice will therefore become more plastic at the bottom than at the top. The shear stress tending to move the mass of ice is known to increase linearly with depth in the ice, and therefore the shear distortion will take place predominantly in the lowest layers. It does not matter very much if, in the analysis, the distortion is regarded as slipping on the rock bed rather than very intense shear in the lowest layer.

The movement of the ice-sheet is outwards towards the unconstrained perimeter, and the calculated strain rates at the ice – rock interface are of the order of about 10^{-2} per annum. This is much higher than the slow rate (about 10^{-4} per annum) of the squeezing down movement of vertical compaction, which is partly or entirely compensated by the addition of new material by snowfall. However, it is the weight of accumulated snow that ultimately provides the driving force for the ice-sheet, and the connexion between the vertical and the outward strains in the ice is such that, in a steady state, the outflow is just sufficient to balance the accumulation.

A simple model of the ice-sheet shows that the steady-state thickness of the ice is proportional only to the fifth or sixth root of the accumulation. This means that the height of the ice-sheet is very insensitive to even long-period changes of accumulation, and it is for this reason that calculations of the equilibrium form of an ice-sheet can be made with fair accuracy without a knowledge of the accumulation. The relevant measurements that are required, therefore, from the field experiments are a knowledge of the topography, the thickness of the ice, and the past and present rates of accumulation.

M. Imbert's results covered a traverse, 300 miles long, running inland from the French International Geophysical Year base in Adelie Land. In the 1957–58 season seventy-five shots were fired to obtain seismic reflexion results at twenty-five stations. The recording gear covered the nominal frequency-range of 600 c./s., but as with most Arctic and Antarctic seismic investigations it was found desirable to put the charge as deep as possible into the layers of poorly compacted snow. A charge of 1 kgm. of high explosive at a depth of 18 m. was found to give readable reflexions, and the quality of a number of 'typical records' that were shown were certainly excellent. Mr. Pratt managed to bury some of his charges to a depth of 12 m., but this was not really deep enough, and in many cases lack of time forced him to be content with surface shots. It is noticeable that the reflexions do not stand out so clearly as some of M. Imbert's, but care must be taken in ascribing record quality entirely to the effect of depth of charge, since some results from the British North Greenland Expedition show that unexplained phenomena deep down in the ice also have considerable effect on the strength of reflexions.

The French seismic profile was supplemented in 1958–59 by seventy gravity stations, and the topography of the surface of the ice-sheet was measured to an accuracy estimated at 15–20 m. Barometric heights were backed up by estimates of atmospheric pressure obtained from radiosonde measurements. The mean height of bedrock was 40 m. below sea-level along the traverse, but elevations and depressions of several hundred metres were observed about this mean. If h km. is the height of the surface above sea-level at point x km. inland, then the surface of the ice fitted the ellipse:

$$\left(\frac{h}{2\cdot 68}\right)^2 + \left(\frac{550 - x}{550}\right)^2 = 1$$

with a root-mean-square error of ± 25 m.

The profile presented by Mr. Pratt covered the 2,000-mile course of the Commonwealth Trans-Antarctic Expedition. The seismic picture was different from that of other observers in that the ice – rock interface was, except for two troughs on the Weddell Sea side of the South Pole, well above (about 1,500 m.) sea-level. This may be accounted for on the Ross Sea side of the pole by the fact that the course of the expedition lay over the foothills of a known mountain range.

The gravity measurements were checked at the South Pole and at the Ross Sea, but the uncertainty about height in between gives a possible error of 25–50 mgal. The estimated error due to drift is much less than this, of the order of 5 mgal. The gravity results support the seismic picture, and Bouguer anomalies have been drawn assuming the profile found from the seismic measurements, together with a rock density of 2·1 gm./cm.^{3}. There is a large anomaly of − 200 mgal. which cannot be explained away by the uncertainties of the measurements. It appears that the ice-sheet must have been subject to a much greater loading in the past than is effective to-day, and that the Antarctic land mass is, like Scandinavia, tending to rise. It would be most interesting to make a careful series of elevation measurements, but the technical difficulties of such observations from a continent fringed with ice are considerable.

A single American seismic result at the South Pole differed from the several that Pratt obtained in the vicinity of the pole, and this was explained by the inherent difficulty of interpreting an isolated record taken under the difficult conditions pertaining to ice-sheets. Pratt had gained a great deal of experience by the time the pole was reached, and the polar observation was a continuation of a whole series of reflexions on the profile hundreds of miles long, so that, apart from the fact that several independent results were obtained, Pratt's value must be accepted rather than the much deeper American figure.

A short refraction line at the South Ice station, 300 miles inland from the main Shackleton base, showed that the velocity in the 80–90 metre thick surface layer varied from 0·5 to 3·96 km./sec., in agreement with observations in other parts of the world. An interesting point emerged from the refraction results. The line ran over undulating snow, but there was no sign on the record of the surface variations in height. It must be assumed, therefore, that the troughs of the undulations consist of lower-velocity material than do the humps. Some shots fired on the ice-shelf yielded reflexions from the sea bed, but not from the bottom of the ice. This is a familiar experience with Antarctica geophysicists, but Pratt has pointed out that a unique solution of ice thickness can be obtained from the travel time of waves reflected from the sea-bed.

Dr. Lister's simple method of following the accumulation of snow by laying down strings at fortnightly intervals and afterwards checking their profile by digging was supplemented by counting the years indicated in the stratification caused by seasonal changes in climate. Pits and drilled cores at South Ice enabled Lister to look back to the year 1895, and across the continent twenty bore-holes reached back twenty years and sixty more were deep enough to include the deposition of the past five years. Along the central portion of the traverse followed by the Trans-Antarctic Expedition the deposition-rate was found to be fairly constant at 8–9 cm. water equivalent a year. This is rather higher than the 6 cm. found by the American observers at their South Pole Base, but may be accounted for by the fact that much of the expedition's route followed a trough in the surface topography. The accumulation increases to about 25 cm. water equivalent at the edges of Antarctica, and Lister calculates a deposition-rate of 13·1 gm./cm.^{2}/year as an average over the whole continent. The wastage is assessed at 10·1 gm./cm.^{2}/year mainly made up of 5·0 melting, 4·0 icebergs, 1·0 evaporation and 0·1 deflation. It appears then, from the present-day observations, that there is a net gain of ice, a result (ignoring any time-lag) opposite to that indicated by the negative gravity anomaly. During the discussion it became apparent that the figures for melting and for loss by breaking off of ice-floes might be changed in the light of other observations, but in any event the present material balance was one that applied to decades rather than to the thousands of years (at least) during which changes in the ice-cap, sufficient to account for the gravity results, would be expected to take place.

Some of Lister's observations made it clear that precipitation favoured hollows rather than the crests of undulations, and that there was a migration of the crests with time. Nye raised the question of whether the presence of the undulations might affect the travel of the whole sheet, because their presence implies a big change of slope over a distance larger than the thickness of the sheet. There was clearly a mechanism here which could give local fluctuations of velocity and hence it would be very difficult to make sense of any isolated measurements of ice-sheet velocity. It is possible that the movement of the crests is only apparent, and is caused by the erosion of hard wind-blown snow at the crests of the undulations, with a simultaneous build-up of a new crest above the snow-filled troughs. Whether they are caused by aerodynamic or by hydrodynamic means, the undulations and sastrugi deserve further attention, and the results that have been collected recently should call forth a new advance on the theoretical side.

T. F. GASKELL

THE NATIONAL SCIENCE FOUNDATION

REPORT FOR 1957–58

MORE than half the eighth annual report of the National Science Foundation for the year ended June 30, 1958*, is occupied by appendixes listing the membership and staff of the Board, its committees and advisory panels, grants for basic research, fellowship awards, publications of the Foundation and others resulting from research grants and fellowships. The latter now runs to some 1,315 items, compared with 850 in 1956–57, and is arranged according to the several divisions of the Foundation. Fellowship awards during the year totalled 1,527, amounting to about 5·6 million dollars in value. Of these, 408 were in the biological sciences, 314 in physics and astronomy, 306 in chemistry, 206 in mathematical sciences, and 193 in engineering. Of the total, 1,084 were predoctoral, 227 postdoctoral and 216 in the science faculty programme for improving the quality of science teaching. Grants for research amounted to more than 19 million dollars, and of these 1,120 grants, 605, totalling 8,881,130 dollars, were in biological and medical sciences; 466 grants, totalling 9,507,825 dollars, in mathematical, physical and engineering sciences; and 49 grants, totalling 725,950 dollars, in social science. During the year, 190 scientists received grants, totalling 113,220 dollars, in support of travel to international scientific meetings, and the Foundation sponsored and provided partial support for thirty-four scientific conferences and symposia.

Reviewing the support given to basic research in the sciences, in the Division of Biological and Medical Sciences, the report stresses the clue to the control of tuberculosis provided by the study of the honey guide, a wax-eating bird found primarily in Africa, from the intestinal tract of which a wax-splitting bacterium was isolated that contains a protein which inhibits the growth of the tubercle bacillus in tissue cultures. Doubts have been thrown on the basic genetic axiom regarding the individuality of genes by the discovery that the gene in corn which produces colour in the kernel can be permanently modified by bringing it into combination with a particular partner gene. Results have been obtained suggesting that some plants may operate as a well-knit group or unit having a common physiology, and it has also been found that nerve growth factors similar to the tumour factors are present in the salivary glands of the mouse and rat, in snake venoms and in the venom of the Gila monster. Sex hormones have been found to control growth in the more primitive plants such as water moulds and ferns, and protein-like material has been produced by application of heat (170° C.) to mixtures of amino-acids. The discovery of a method for introducing sulphydryl and disulphide groups into proteins and protein-like molecules has permitted the physical, chemical and physiological characteristics of proteins to be altered at will. Deoxyribonucleic acid has been synthesized by adding an enzyme obtained from bacteria to a previously prepared mixture of nucleic acids, and in studies of the growth of *Brucella abortus* and *Diplococcus pneumoniae* addition of a mixture of bacterial deoxyribonucleic acid and deoxyribonuclease to growing cultures of these organisms had striking effects upon the selective establishment of virulent cells in an initially non-virulent population.

---

* National Science Foundation. Eighth Annual Report for the Fiscal Year ended June 30, 1958. Pp. xv+246 (8 plates). (Washington, D.C.: Government Printing Office, 1959.) 1 dollar.

In the Division of Mathematical, Physical and Engineering Sciences, the report directs attention to the cloud-seeding experiments near Tucson, Arizona, where radar observations indicated that precipitation from larger seeded clouds was greater than from similar unseeded ones; to the development of a neurological instrument which enables ultrasonic waves to be used to cut out tiny regions of the inner brain without disturbing the inner structure; to a laboratory model of a stream which, used in conjunction with a high-speed motion-picture camera, has clarified the motion of individual sand grains in a flowing stream; to the laboratory confirmation of the hypothesis that pegmatites are relatively dry melts (magmas) and are closed physico-chemical systems, and that the giant crystals are formed during a 'second boiling'; to the development of techniques whereby free radicals are formed and immediately trapped on cold surfaces (− 424° F.); to the measurement of variations in the pull of gravity in Utah and Eastern Nevada which have permitted charting the major contours of the buried bedrock and given important clues to the configuration of the fault blocks and other structural patterns; and to the total stereospecific synthesis of several antibiotics and the production of a substance identical with natural rubber in physical characteristics by careful control of the spatial relations of the groups in the molecule.

In the Social Science Research Programme, electronic computers have been used to determine more quickly and sensitively the stages of the business cycle and to separate significant trends from temporary irregularities.

Besides the surveys made by the Foundation of the research and development effort of the United States and a brief report on the Conference on Research and Development and its Impact on the Economy called by the Foundation for May 20, 1958, the report summarizes the Foundation's activities in the International Geophysical Year. Apart from the fellowship programme already noted, the report deals at some length with the work which the Foundation is doing to improve science education. For this purpose the Foundation received a supplemental appropriation of 9 million dollars, which was used for the award of additional fellowships and to assist the attendance of more high-school science teachers at the summer institutes, of which 126 were held in 1958 in forty-seven States and three Territories. For 1959 the appropriation for the Foundation's educational programmes was increased to about 60 million dollars, but the educational implications of the report are discussed separately.

ENERGETIC COUPLING IN THE RESPIRATORY CHAIN

By Dr. POUL E. GLAHN and Dr. SIGURD O. NIELSEN

Carlsberg Laboratory, Copenhagen

THE important part played by the energetic coupling between substrate oxidation and adenosine triphosphate (ATP) synthesis (oxidative phosphorylation) in the energy economy of animal cells is well known[1]. The demonstration, *in vitro*, of energetic coupling between oxidation and reduction of carriers in the respiratory chain and adenosine triphosphate synthesis at present requires particulate preparations containing either mitochondria or multifunctional mitochondrial fragments. Experiments with such preparations indicate that the oxidation of reduced diphosphopyridine nucleotide (DPNH) by ferricytochrome *c* is coupled to the synthesis from adenosine diphosphate and free orthophosphate (P_i) of two moles of adenosine triphosphate per mole of reduced diphosphopyridine nucleotide oxidized[2,3] and that the oxidation of ferrocytochrome *c* by molecular oxygen is coupled to the synthesis of at least one mole of adenosine triphosphate (two moles being energetically possible) per two electrons transferred[3,4,14]. The detailed mechanism of this energetic coupling in the respiratory chain is essentially unknown in contrast to the coupling at substrate level[5] and its elucidation constitutes a major problem of contemporary biochemistry. In view of this fact and the great difficulty of experimental work with multifunctional, highly organized, and relatively ill-defined particles, it is amazing that no more speculation has appeared in the literature concerning the chemical nature of the coupling reactions, in particular the primary ones involving oxidation-reduction of respiratory carriers. It would appear that 'educated guesses' at the possible organic chemistry of these primary coupling reactions involving known or hypothetical respiratory carriers might be useful in the planning of new experimental approaches. The present article presents some ideas on the primary coupling reactions at all three phosphorylating sites between oxygen and reduced diphosphopyridine nucleotide. We feel less hesitant about publishing these views, which may eventually turn out to be wrong, because it has been possible to consider the primary coupling reactions at all four phosphorylating sites, including those at the cytochrome a_3- and substrate-levels, from a unified point of view.

The total number and location of carriers in the respiratory chain are still unknown, although it is generally agreed that diphosphopyridine nucleotide

(DPN), flavine adenine dinucleotide (FAD), cytochromes c, a, and a_3 are in the chain in the order given[6]. Tentative coupling schemes based on these established carriers have been proposed; for example, the reaction:

$$\text{DPNH} + X^{\bullet} + \text{FAD} \rightarrow \text{DPN} \sim X + \text{FADH}$$

has been suggested[1] as the primary reaction for the phosphorylation site in question. The whereabouts of the point of attachment of X to the nucleotide in the energy-rich compound DPN $\sim X$ is, however, left open.

Recently the organic chemistry of the coupling reactions has received some attention. Harrison[7] and Todd and co-workers[8] have suggested the phosphorylated form of a hypothetical, hydroquinone-type respiratory carrier as an intermediate which afterwards transfers its phosphate group to adenosine diphosphate following oxidation to the quinone-level. Similarly, Lindberg and co-workers[9] have postulated phosphorylation in the 2-position of the reduced *iso*alloxazine ring of reduced flavine adenine dinucleotide. Upon oxidation the phosphate group is transferred to adenosine diphosphate. In the case of hydroquinone phosphate experimental evidence is available that the phosphate group may actually be transferred to adenosine diphosphate after oxidation[8]. These examples bring out the essence of the coupling problem. When oxidized carrier A oxidizes reduced carrier B with the coupled synthesis of adenosine triphosphate, A_{ox} reacts directly with B_{red} only after combination of one or other of them with a group X (not necessarily phosphate) forming a 'low-energy' bond (standard free energy of hydrolysis $\Delta F^0 \simeq 0$). Upon reduction of A_{ox}—X by B_{red} or oxidation of B_{red}—X by A_{ox} the energy-rich compounds ($\Delta F^0 < -8$ kcal./mole)[10] $A_{\text{red}} \sim X$ and $B_{\text{ox}} \sim X$, respectively, are formed. In terms of standard oxidation potentials, E^0, this means that E^0 for the couple $A_{\text{ox}}—X/A_{\text{red}} \sim X$ is decreased by more than $8{,}000/96{,}500 \times z \times 0{\cdot}24$ V. compared with E^0 for the couple $A_{\text{ox}}/A_{\text{red}}$. This corresponds to 0·35 V. for a one-electron process ($z = 1$) and 0·17 V. for a two-electron process ($z = 2$). Similarly, E^0 for the couple $B_{\text{ox}} \sim X/B_{\text{red}}—X$ is increased by more than 0·35 V. for a one-electron process and 0·17 V. for a two-electron process compared with E^0 for the couple $B_{\text{ox}}/B_{\text{red}}$.

We shall now show how reduced diphosphopyridine nucleotide, reduced flavine adenine dinucleotide and ferricytochrome a_3 may combine through low-energy linkage with a nucleophilic group X^- (RS$^-$, RCOO$^-$, $H_2PO^-_4$, etc.) in such a way that the compounds DPN $\sim X$, FAD $\sim X$, and (Fe(II) cyt–a_3) $\sim X$ are energy-rich. The coupling schemes shown in Fig. 1 include the primary coupling reaction at substrate level[5] for comparison.

To see how these reaction schemes for diphosphopyridine nucleotide and flavine adenine dinucleotide transform the bond between X and the respiratory carrier from a low-energy bond on the left to an energy-rich bond on the right, the main bond systems in which resonance stabilization occurs are indicated in the formulæ (Fig. 1). Without going into details (for example, ref. 11) we may state that it follows from the uncertainty principle that the energy due to resonance of the molecule falls roughly as n^{-2}, where n is the number of bonds involved in a resonating bond system that resonates between structures of comparable energy. It follows that removing the amide carbonyl group of reduced diphosphopyridine nucleotide or the 4-carbonyl group of reduced flavine adenine dinucleotide from the resonating five-bond system to which it belongs (similar in both compounds) by substituting X for O occurs at the expense of only a small loss in resonance stabilization energy, because the molecules are still able to resonate over the four remaining bonds indicated in the formulæ. On the other hand, if the nucleotides are in the oxidized forms, and the same carbonyl groups are removed by substituting X for O, this occurs with a considerable loss in resonance stabilization energy which amounts to almost the whole of that of the amide group. The DPN $\sim X$ and FAD $\sim X$ bonds may, therefore, be considered as energy-rich. This conclusion is supported by a comparison of the standard oxidation potentials E^0 for the couples DPN/DPNH and acetyl-DPN/acetyl-DPNH (in the latter a methyl group is substituted for the nicotinamide amino-group). E^0 for acetyl-DPN is 0·072 V. higher than E^0 for DPN (ref. 12). The resonance stabilization energy in acetyl-DPNH is smaller than in DPNH $-$ X because resonance in the former but not in the latter involves a charge separation; it is therefore reasonable to suppose that E^0 for the couple DPN $\sim X$/DPNH — X might be at least 0·17 V. higher than that of the couple DPN/DPNH.

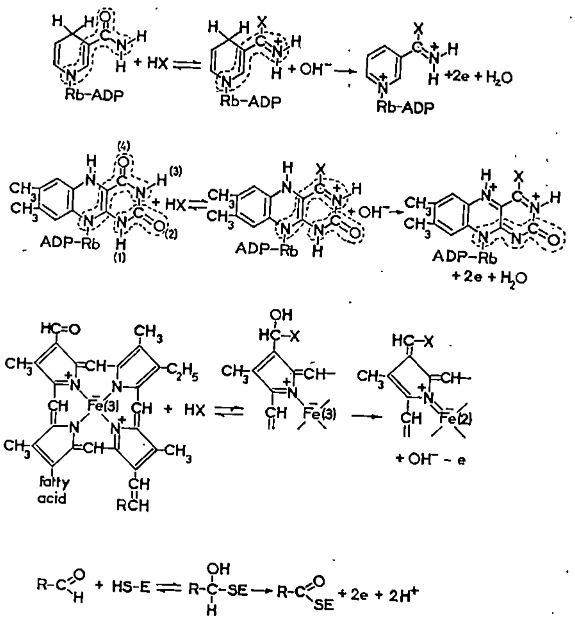

Fig. 1

It will be noticed that in the reaction schemes above it is the 4-position which combines with X, whereas Lindberg and co-workers[9] suggested the 2-position as the point of attachment. On the basis of considerations of resonance energy, like those above, the 2-position, however, appears to be less suited than the 4-position for engaging in the primary coupling reaction.

The number of electrons transferred in the energetic coupling reaction in the part of the respiratory chain between cytochrome c and oxygen is unknown[13]. A two-electron reaction involves either a higher oxidation state than ferricytochrome or a strong interaction between two cytochrome prosthetic groups, neither of which has been demonstrated. A one-electron coupling reaction might imply a maximal P/O ratio of 2 for the oxidation of ferrocytochrome c

by oxygen. Experimental ratios for this part of the respiratory chain are all smaller than one, possibly because of the experimental difficulties encountered. A ratio of 2 for the oxidation of ferrocytochrome *c* by molecular oxygen remains a definite possibility[14].

The reaction scheme proposed for the energetic coupling in the cytochrome system involves the formyl group of porphyrin *a* of cytochrome a_3 and is a one-electron process. The porphyrin *a* formula shown is the one given by Dixon and Webb[15], based on the work of Lemberg and co-workers[16]. A porphyrin formyl group is not present in cytochromes *b* and *c*. The formyl group tends to withdraw electrons from the rest of the iron-porphyrin complex[17] and there are various reasons, for example the high intensity of the α-band, for believing that there is much double-bond character in the iron-pyrrole nitrogen bond in ferrocytochromes *a* and a_3. The replacement of the formyl oxygen atom by X in ferrocytochrome a_3 may, therefore, involve a considerable gain in free energy so that (Fe(II) cyt–a_3) $\sim X$ is energy-rich. This suggestion is supported by available E^0 data for substituted iron phenanthroline complexes and for various hæmochromogens. In sulphuric acid Smith and Richter[18] found E^0 for iron 5-nitro-1,10-phenanthroline to be 1·25 V. compared with 1·06 V. for the unsubstituted iron 1,10-phenanthroline. At 30° C. and *p*H 9·63 the following E^0 values have been reported[19]: for the dicyanide hæmochromogens of coproporphyrin (all side-groups saturated) – 0·247 V., and of sphirographis porphyrin (a formyl and a vinyl side-group) – 0·113 V. The introduction of the electron-withdrawing groups NO_2 and CHO into the phenanthroline and porphyrin molecules increases the E^0 value for the iron complexes. The increase is less than the required 0·35 V. for a one-electron process, but this may tentatively be ascribed to the difference between porphyrins and other iron ligands in dicyanide sphirographis hæmochromogen, dicyanide coproporphyrin hæmochromogen, and cytochrome a_3.

Although porphyrin *a* is the prosthetic group of both cytochromes *a* and a_3 we prefer to write the primary coupling reaction with cytochrome a_3, because the E^0 span between cytochromes *c* and *a* is only 0·03 V., that is, too small for a coupled phosphorylation to occur[4]. The one-electron coupling reaction proposed is compatible with an overall P/O ratio of 1 for the oxidation of ferrocytochrome *c* by oxygen if molecular oxygen or hydrogen peroxide is reduced by one mole each of cytochrome *a* and cytochrome a_3 in a two-electron process.

The three primary coupling reactions proposed are analogous to the primary coupling reaction at substrate-level in so far as they involve a low-energy substitution at a carbonyl group and a gain in resonance stabilization energy on hydrolysis of the energy-rich form. The transfer of bond energy from $A_{\text{red}} \sim X$ or $B_{\text{ox}} \sim X$ to adenosine triphosphate may, therefore, also take place by analogous or similar mechanisms at all three phosphorylation sites in the respiratory chain. The suggested involvement of the oxidized forms of diphosphopyridine nucleotide and flavine adenine dinucleotide in energy-rich linkages is in agreement with labelled phosphate and adenosine triphosphate exchange experiments[3,20].

We are happy to acknowledge the interest and kind advice of Prof. K. Linderstrøm-Lang.

USE OF RADIOACTIVE TRACERS IN STUDIES OF THE SHOOT APEX

By DR. A. BOOTH*, DR. E. G. CUTTER, DR. S. N. POSTLETHWAIT†, B. R. VOELLER‡ and PROF. P. F. WAREING§

Department of Botany, University of Manchester

IN studies of morphogenesis at the shoot apex, hypotheses are often advanced which involve the transport of various substances, and their accumulation at specific sites, within the meristematic regions. Such hypotheses are difficult to test by means of standard physiological techniques because of the minute volumes of tissue involved. One possible approach to these problems is the use of radioactive isotopes, which have, indeed, already been successfully employed in studies of histogenesis in root apices[1] and, more recently, in the shoot apex of *Pinus*[2]. Previous work with radioactive tracers on apical meristems has been confined to autoradiography of sectioned material, thus restricting the area of tissue which it is possible to examine at any one time. A possible technique for obtaining autoradiographs of the whole surface area of intact or surgically treated shoot apices has been devised by us. This technique renders it possible, for example, to compare in a single film autoradiographs of visible leaf primordia, prospective leaf sites and the whole surface of the shoot apex, which could never all be viewed simultaneously in section. It is, however, applicable only to the investigation of phenomena occurring near the surface of the tissues.

Shoot apices of *Dryopteris aristata* (*austriaca*) were used, both because this fern has already been the subject of extensive experimental investigation and because its apical region is of suitable form for the application of the technique described, in that it comprises a central apical cone and a number of small, spirally arranged leaf primordia which are not in contact (Fig. 1). The shoot apex was exposed to view by removing the older leaves and all scales. A cylinder of rhizome tissue, bearing the apical meristem at its tip, was then removed with a cork borer (9–12 mm. diameter), and trimmed to suitable length (5–10 mm.). The number of leaf primordia present, the stage of the plastochrone, and the direction of the phyllotactic spiral were noted, and the position of the next leaf primordium to arise (I_1) was marked. After allowing a 24-hr. recovery period, the cylinders of tissue were placed in a vertical position on filter paper moistened with the isotope solution, contained in a moist glass chamber. The isotopes used in this preliminary survey were phosphorus-32 (as a solution of orthophosphate) and 8-adenine sulphate labelled with carbon-14. An activity of 3–5 μc./ml. of solution (without the addition of carrier) was found to be suitable.

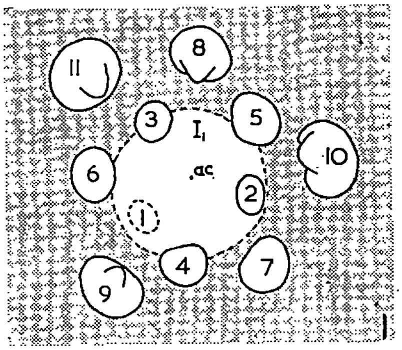

Fig. 1. Drawing of an apex of *Dryopteris aristata* similar to those from which the autoradiographs shown in Figs. 2 and 3 were obtained. Eleven young leaf primordia (P_1–P_{11}) are present; the position of I_1 (the next primordium to be formed) is also indicated. The apical cone is outlined with a broken line; the sub-apical region is stippled. *ac*, apical cell. (× 18)

The cylinders of tissue were removed from the dishes after an appropriate period of uptake, and thoroughly washed to remove any isotope solution on the surface. Thin, semi-circular slivers of tissue, about 4 mm. diameter and 1–2 mm. thick, bearing the apical meristem were excised from the cylinders and quickly affixed to small glass slides with 'Durofix'.

In a dish of water, small trapezium-shaped pieces of fast autoradiographic stripping-film (Kodak *AR* 50) were floated on to the surface of the apices and carefully orientated to allow subsequent recognition of the I_1 position. Excess water between the apex and the film was removed with filter paper; this considerably improved the subsequent fit of the film. The film was then quickly dried over the surface of the tissue with a stream of warm air from an industrial blower held at a distance of about 3 in. for 15 sec. The timing of this operation is important; with a shorter period of heating, the fit of the film was greatly impaired, whereas with more than 15 sec. heating, subsequent removal of the film from the tissue was rendered impossible. After this treatment the slide bearing the apex covered with film was placed in a light-tight container and maintained at a temperature of − 20° C. during the period of exposure. With phosphorus-32 an uptake period of 3–5 days with an exposure-time of 36–72 hr. usually gave satisfactory results, though longer periods of exposure were sometimes necessary (Fig. 3). Some differential blackening of the film was obtained after only 24-hr. uptake, with a long exposure period (11 days).

After exposure of the film, the slide was removed from its container, and the film was developed and fixed while still adhering to the apex. Since the film could not be examined satisfactorily with the opaque tissue beneath it, it was removed from the apex with fine forceps under water, and floated on to a slide. Areas of blackening on the film were then compared with the various regions of the apex, before

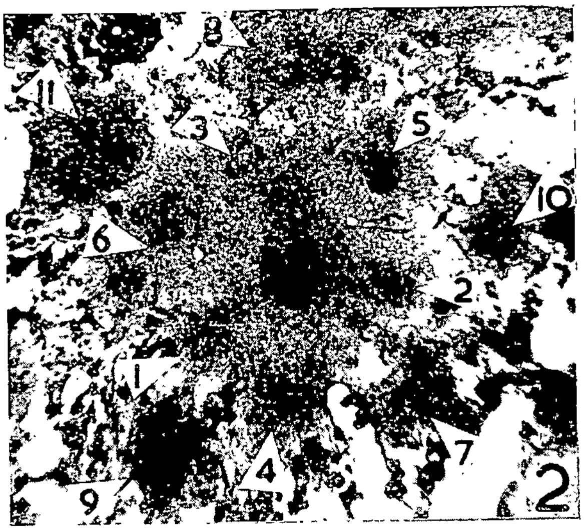

Fig. 2. Autoradiograph of an apex of *D. aristata* treated with phosphorus-32. Primordia 1–11 are present; P_8 and P_{10} were damaged. All the leaf primordia (arrowed) and the tip of the shoot apex (centre) are indicated by areas of blackening in the film. Totally dark areas, near the edge of the figure, are pieces of apical tissue adhering to the film; the film is also torn in places, leaving clear areas. Period of uptake of isotope, 6 days; film exposed for 40 hr. (× 20) (*Photo: G. Barker*)

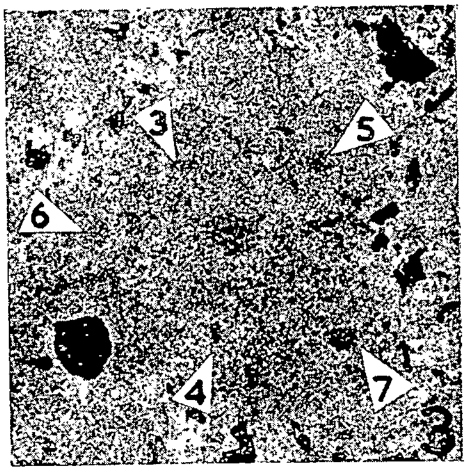

Fig. 3. Autoradiograph of an apex treated with phosphorus-32. Primordia 1–7 were present; P_1 (between 4 and 6) and P_2 (between 5 and 7) are not obvious in the film, but P_3–P_7 (arrowed) and the tip of the shoot apex (centre) are represented by blackened areas. Totally dark areas are pieces of tissue adhering to the film. Period of uptake of isotope, 3 days; film exposed for 14 days. (× 20) (*Photo: G. Barker*)

discarding the latter. Since the position of I_1 can be determined from the shape of the piece of film, and the direction of the phyllotactic spiral and the number of leaf primordia present were recorded at the beginning of the experiment, areas of blackening on the film may readily be assigned to the appropriate primordia or regions of the apex long after these tissues have been discarded.

The results thus far obtained indicate the potential usefulness of the method. Figs. 2 and 3 illustrate films obtained from apices treated with phosphorus-32. Considerable blackening due to silver grains is present over the whole area of film covering the tissue, as would be expected with an isotope of the range of phosphorus-32; but the blackening is not uniform. It is concentrated, in fact, at the positions of the leaf primordia; blacker areas can sometimes be detected down to and including the youngest leaf primordium, P_1 (Fig. 2). Damaged leaf primordia produce blackening comparable to that from intact primordia. Scales, scale primordia and those regions of the apex from which scales have been removed are recorded as paler areas in the film. The scope of the technique is not restricted to inorganic phosphorus-labelled compounds, but can be extended to organic carbon-labelled compounds, since comparable results were also obtained with adenine labelled with carbon-14. Films from control apices, placed on water containing no isotope, showed no appreciable blackening.

In conclusion, it should perhaps be emphasized that this method is still not without difficulties, and that a relatively small number of satisfactory demonstrations has been obtained from a considerable number of specimens. Moreover, these preliminary results have only demonstrated accumulations of tracer in visible primordia. The really effective contribution which we hope may be obtained from the method would be demonstrations of the accumulation of specific metabolites: (*a*) as a result of the presence of various experimental incisions, and (*b*) in the I_1, I_2 and even I_3 positions, thus providing evidence of the existence and approximate dimensions of centres of growth which are not as yet morphologically or histologically detectable. This aim has not yet been achieved, even in actively growing apices. However, in conjunction with existing experimental results and morphological techniques, it is felt that this method, when extended, may well throw light on these and other aspects of the physiology of the formative regions of plants, a difficult and little investigated field.

RADIOCARBON MEASUREMENTS ON SAMPLES OF KNOWN AGE

By W. S. BROECKER, EDWIN A. OLSON and JUNIUS BIRD

Lamont Geological Observatory, Columbia University, and
American Museum of Natural History, New York

THE radiocarbon age method is at present based on the assumption that the ratio carbon-14/carbon-12 in atmospheric carbon dioxide has remained constant with time. The approximate validity of this assumption was originally demonstrated by Arnold and Libby[1], whose measurements of historically and tree-ring dated samples showed no significant deviations over the past 5,000 years (that is, none beyond 5 per cent of the age). Since then, other far more precise measurements have appeared in the literature[2–4], generally showing consistency between radiocarbon and absolute ages.

From a theoretical point of view, there are three possible reasons why the atmospheric ratio of carbon-14/carbon-12 might change with time: first, fluctuations in the rate of production of carbon-14; secondly, variations in the amount of stable carbon in the dynamic reservoir; and thirdly, variations in the pattern of inhomogeneous distribution of carbon-14 within the dynamic reservoir.

Recently the first and third possibilities have been discussed. Assuming that Thellier's[5] residual magnetism measurements of ancient French bricks typified the whole earth, Elsasser, Ney and Winckler[6] calculated that the greater magnetic field intensity in the past deflected enough cosmic radiation from the Earth to lower significantly the production-rate of carbon-14 and consequently its concentration in the atmosphere. They calculated that 2,000-yr. samples would thus give radiocarbon ages of 2,240 years. In addition, Broecker *et al.*[7], reasoning from Worthington's[8] suggestion of catastrophic overturn in the oceans, suggested that such changes in the rate of formation of deep water, if on a world-wide scale, would measurably affect the carbon-14/carbon-12 ratio in the atmosphere. If, for example, the rate of formation of bottom water were accelerated, carbon-14-depleted bottom water would reach the surface at a faster rate, reducing the carbon-14/carbon-12 ratio in the surface waters and in turn in the atmosphere. Although the results of Broecker *et al.*[7] failed to show any significant variations which might be related to non-equilibrium circulation of the oceans, DeVries[3] has recently obtained results demonstrating small oscillations (± 1 per cent) in the ratio carbon-14/carbon-12 of the atmosphere over the past few hundred years. He feels that these variations correlate well with historical climatic records in the manner predicted if the cause were variation in the rate of formation of deep water.

By applying corrections to certain published carbon-14 measurements of samples of known age, Crowe[9] has postulated that the past few thousand years have witnessed atmospheric variations over a range of 10 per cent. Munnich, Ostlund and de Vries[10] and Barker[11] have shown, however, that Crowe's corrections are unrealistic; with more reasonable assumptions, his deviations disappear.

In order to define the atmospheric carbon-14/carbon-12 ratio over historic time, a large number of samples will have to be measured from many areas and at closely spaced times. This will necessitate the co-operation of a number of laboratories. As a contribution to the problem, a number of Lamont measurements on samples of known age are reported here (summarized in Table 1). Since the results are related to the international oxalic acid carbon-14 standard distributed by the U.S. National Bureau of

Δ^{14}C average = +3 (excluding *L*-113). Standard deviation = 17

* Ages are computed using the average Δ^{14}C as the control value.

Standards, they can be compared directly with those obtained at other laboratories.

The results are expressed in terms of Δ^{14}C, defined as follows:

$$\Delta^{14}\text{C} = \delta^{14}\text{C} - 2\delta^{13}\text{C}\left(1 + \frac{\delta^{14}\text{C}}{1{,}000}\right) - 50{\cdot}0$$

where

$$\delta^{14}\text{C} = \left\{\frac{A^{*}(\text{sample}) - 0{\cdot}950A^{0}(\text{oxalic acid})}{0{\cdot}950A^{0}(\text{oxalic acid})}\right\} \times 1{,}000$$

and

$$\delta^{13}\text{C} = \left\{\frac{R\,(\text{sample}) - R(\text{belemnite standard})}{R(\text{belemnite standard})}\right\} \times 1{,}000$$

Symbols used are defined as follows: δ^{14}C and δ^{13}C = per mille (not per cent) differences from arbitrary standards (consequently, Δ^{14}C is in per mille); A^{*} = carbon-14 activity of the sample corrected for radioactive decay between formation and measurement of sample; A^{0} = carbon-14 activity of the standard corrected for decay between January 1, 1958, and the time of the measurement; R = ratio carbon-13/carbon-12 as determined on a mass spectrometer. The constants − 50·0 and 0·950 are introduced so that the values for Δ^{14}C and δ^{14}C for pre-1900 woods (the usual modern control standards of radiocarbon laboratories) fall close to zero on the scale. (A more complete discussion of the scale used in this communication will be published in the first radiocarbon supplement of the *Americal Journal of Science* (1959).) By introducing δ^{13}C, a term based on the stable isotope ratio carbon-13/carbon-12 of the gas used for the radioactivity assay, the term δ^{14}C is corrected for isotope fractionation during the photosynthetic processes and/or during the laboratory preparation of the sample gas. Thus, if the ratio carbon-14/carbon-12 for the atmosphere is geographically uniform and has remained constant in the past, as at present assumed in dating, the Δ^{14}C values of all historically dated terrestrial plant materials should be the same within the experimental error.

The Δ^{14}C results of measurements on twelve samples which are dated historically or by tree-rings are listed in Table 1, as well as plotted in Fig. 1. Before examining the results for the purpose of drawing conclusions, it would be well to consider how the absolute ages of the samples were obtained.

Two samples, Pompeiian bread and Mayan lintel wood, are dated historically. The bread remains found at Pompeii were certainly charred in the great ash fall of A.D. 79, so that the age of the wheat is 1,879 years plus the period of grain storage; the latter is probably less than two or three years and thus negligible. In the case of the lintel wood, the absolute age is obtained from the Mayan date of 9.15.0.0.0 carved on the lintel; according to the Spinden correlation of the Mayan and Christian calendars, the date is equivalent to August 30, 481. Thus, the age of the wood is 1,477 years plus the period between growth and cutting of the tree, estimated from ring counts to be about 25 years (that is, 1,502 years). On the other hand, if the Goodman–Martinez–Thompson correlation is correct, the age is 260 years less (that is, 1,242 years).

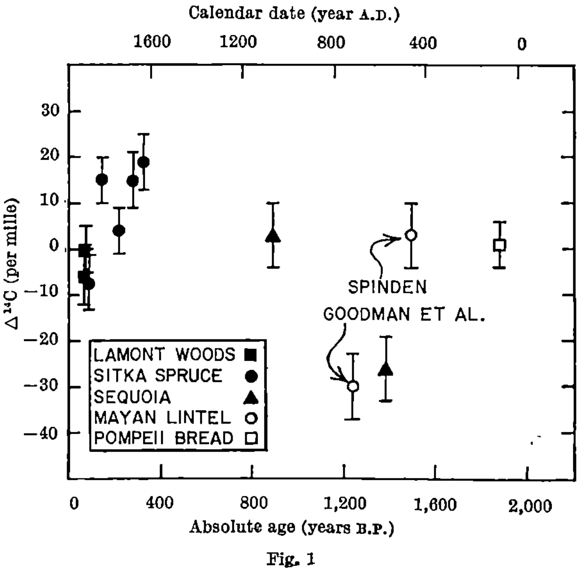

Fig. 1

The other ten samples all involve tree rings representing four individual trees, sequoia, sitka spruce, oak and pine. In all cases, the ages were obtained from the dates of cutting together with ring counts. The sequoia and spruce sections are part of the forestry collection of the American Museum of Natural History in New York City, while the oak and pine trees were obtained from the grounds of the Lamont Geological Observatory. We wish to acknowledge the aid of J. McCormack and F. Scherer, of the Museum staff, in obtaining the sitka spruce samples.

The results show a spread of ± 25 per mille about a mean of + 3 per mille. Since the standard deviation of the results is 17 per mille, in contrast to the measurement error of about 6 per mille, there is little doubt that the results include real differences. As yet it is not certain whether these results reflect world-wide or merely local variations. The three samples of highest activity (spruce woods with ages of 148, 281 and 324 years) are consistent with results obtained by both Munnich[2] and de Vries[3], pointing to a 10–20 per mille higher atmospheric carbon-14/carbon-12 ratio during the period A.D. 1630–1830. On the other hand, the 886-year-old sequoia sample and the Pompeiian bread (A.D. 79) fall close to the average and to wood grown within the last half of the nineteenth century. The results of Munnich[2] and de Vries[3] also provide support for the similarity between the atmospheric carbon-14/carbon-12 ratio of the mid- to late-nineteenth century and the late first century A.D., suggesting a difference no greater than 10 per mille. Unless further radiocarbon results fail to support this similarity, the postulated linear decrease of the Earth's magnetic field suggested by Thellier's[5] residual magnetism data is improbable. Whether the low value represented by the 1,400-year-old sequoia sample is truly representative of a world-wide condition is uncertain. If it is, then the calendar correlation of Goodman *et al.* gains support. But if the average of all samples is more typical of the Mayan atmosphere, the Spinden correlation is favoured.

From the above discussion, it should be clear that more observations on samples of known age are needed to increase the accuracy of radiocarbon dates on recent samples. The job is two-fold : (1) archæologists must be on the alert for accurately dated historical samples (± 10 years) and (2) radiocarbon laboratories must continually increase their counting precision well below the 1 per cent level, an average for the magnitude of variations sought here. With the present observations it can only be said that the radiocarbon age of an atmospherically derived sample younger than 2,000 years will almost always lie within 250 years of the true age.

We gratefully acknowledge the encouragement of Dr. J. L. Kulp in the work reported here. Thanks are also due to James Hubbard and Marylou Zickl for their aid in preparing and measuring the reported samples and to Glen Erickson and Roland Kologrivov for the mass spectrometric measurements of carbon-13/carbon-12 ratios.

REFRACTION OF EXTRA-TERRESTRIAL RADIO WAVES IN THE IONOSPHERE

By M. M. KOMESAROFF and C. A. SHAIN

Radiophysics Laboratory, Commonwealth Scientific and Industrial Research Organization, Sydney, Australia

SEVERAL authors, most recently Chvojkova[1], have derived approximate expressions for the refraction of extra-terrestrial radio waves passing through the ionosphere ; all have assumed a radially symmetrical ionospheric model. However, Smith[2] has shown that the diurnal variation of electron density, especially near sunrise, produces east–west horizontal gradients which result in appreciable changes in the apparent right ascensions of discrete sources. Also, recent work[3] at Sydney has shown that north–south gradients are just as important, and it is clear that an adequate treatment of the refraction problem must take account of departures from spherical symmetry.

For galactic observations at low frequencies, it is essential that some means of estimating the ionospheric refraction should be available, and one of us (M. M. K., in preparation) has derived new expressions for refraction, taking into account the effects of horizontal gradients in electron density and considering the magnitude of the uncertainties involved in the necessary approximations. The analysis has been restricted to the case of a transit radio telescope. Before including the effects of horizontal gradients, that is in the limiting case of a spherically symmetrical ionosphere, it is shown that a source the apparent declination of which is δ' is actually displaced from its true declination by $\Delta(\delta)_s$, where :

$$\Delta(\delta)_s = \sin^{-1}\left[\frac{r_m}{r_b}\sin I_b\right] - I_b - \sin^{-1}\left[\frac{r_m}{r_a}\sin I_a\right] + I_a - \sin^{-1}\left[\frac{r_m}{r_b}\sin(\delta' - \varphi)\right] + \sin^{-1}\left[\frac{r_m}{r_a}\sin(\delta' - \varphi)\right] \quad (1)$$

and the angles I_a, I_b are given by

$$\tan I_a = \frac{\tan(\delta' - \varphi)}{r_a - r_m}\int_{r_m}^{r_a}\frac{dr}{\mu_{f\cos(\delta' - \varphi)}}$$

$$\tan I_b = \frac{\tan(\delta' - \varphi)}{r_m - r_b}\int_{r_b}^{r_m}\frac{dr}{\mu_{f\cos(\delta' - \varphi)}}$$

Here $\mu_{f\cos(\delta' - \varphi)}$ is the refractive index, at a point on the ray with geocentric distance r, for a frequency $f\cos(\delta' - \varphi)$, f being the observing frequency and φ the observer's latitude. r_a and r_b are the radii of the upper and lower 'boundaries' of the ionosphere (that is, 95 per cent of the electrons are in the range $r_b < r < r_a$) and r_m is the radius of the layer of maximum electron density. Provided $(r_a - r_b) < 0{\cdot}1r_m$, the error in equation (1) does not exceed about 10 per cent.

Departures from spherical symmetry lead to extra displacements, in right ascension as well as in declination, proportional to the longitudinal and latitudinal gradients in electron density. If the shape of the layer is everywhere the same, the displacements are proportional to the gradient in f_c^2, f_c being the critical frequency of the layer. Provided the 'effective ionospheric thickness' d, defined in terms of the total electron content by $\int N\,\mathrm{d}r = d.N_{\text{max.}}$, is constant and also that the gradients $(\partial f_c^2/\partial\varphi)$, $(\partial f_c^2/\mathrm{d}L)$ are unidirectional throughout the ray path, then for moderate zenith angles the total change of declination, $\Delta(\delta)$, is given by:

$$\Delta(\delta)\cos^2(\delta'-\varphi) = \frac{d}{2r_b f^2}\left[f_c^2\tan(\delta'-\varphi) - \frac{\partial f_c^2}{\partial\varphi}\right] = d.\rho(\delta) \qquad (2)$$

and the change of right ascension, $\Delta(\alpha)$, by:

$$\Delta(\alpha)\cos\delta'.\cos\varphi.\cos(\delta'-\varphi) = \frac{d}{2r_b f^2}\cdot\frac{\partial f_c^2}{\partial L} = d.\rho(\alpha). \qquad (3)$$

The first term in $\rho(\delta)$ is an approximation from equation (1), and, in the special case defined by $\delta f_c^2/\partial\varphi = 0$, equation (2) reduces to Chvojkova's equation. It is seen that the refraction is proportional to d and hence to the total electron content, so that refraction observations give a new method of estimating this quantity.

Using the Sydney 19·7 Mc./s. Mills cross, many observations of the apparent positions of some of the stronger discrete sources have been made, and the observed refraction has been correlated with ionospheric data from the chain of ionospheric stations, along the east coast of Australia, controlled by the Australian Ionospheric Prediction Service. Values of f_c^2 and its latitudinal gradient were estimated from the simultaneous hourly values of $f0F2$ from the different stations, while the longitudinal gradient was estimated from the time variation. The results of observations of apparent declination of the sources 03*S*3*A*, 09*S*1*A* and 12*N*1*A*, made between September 1957 and May 1958, are presented graphically in Fig. 1.

There is good correlation between $\Delta(\delta).\cos^2(\delta' - \varphi)$, the refraction observed for each source reduced to a common scale, and $\rho(\delta)$ (see equation 1); we infer that for all these observations d was approximately equal to 550 km. An independent estimate obtained from the right ascension data (not shown) was 450 km., but in this case the scatter of the points was much greater. For both right ascension and declination a considerable part of the scatter is due to the uncertainties involved in interpolating from the hourly ionospheric data to the circumstances of each observation. In this connexion, the effects of large ionospheric irregularities (order of 100 km.) could be serious; short-period scintillations (order of 1 min.) have been eliminated by an averaging process in the reduction of the observations.

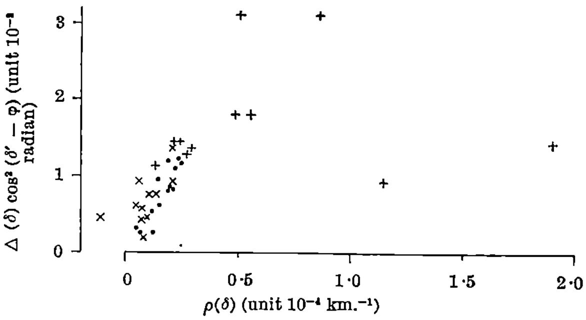

Fig. 1. Refraction under different ionospheric conditions; the quantities plotted are defined in the text. Observations of three discrete sources are indicated separately: ●, 03*S*3*A*; +, 09*S*1*A*; ×, 12*N*1*A*

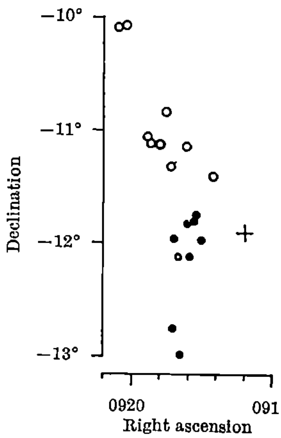

Fig. 2. 19·7 Mc./s. positions of the source 09*S*1*A*. Observed positions are shown by circles and the positions obtained after applying corrections for ionospheric refraction are shown by dots. The cross indicates the 85·5 Mc./s. position of the source

The constancy of the value of d implies that, for these observations, the total electron content of the ionosphere was directly proportional to $(f0F2)^2$.

Evans[4] has published values of the total electron content derived from observations of moon echoes at Jodrell Bank. We have estimated the total electron content to be expected at the time of his observations, assuming the constant value of d = 500 km. deduced from our refraction measurements, and taking $f0F2$ from the Slough data. There is generally good agreement with his observational results, especially in view of the differences in place and time.

As an indication of the astronomical value of the ionospheric refraction corrections, the observed and corrected positions of 09*S*1*A* are shown in Fig. 2. In declination, the scatter has been much reduced and the corrected positions, with two exceptions, are within a few minutes of arc of the 85·5 Mc./s. position[5], after corrections of about 1°. The two exceptional observations are those showing very large refraction and they have obviously been over-corrected; this is probably due to the effects of ionospheric irregularities. In right ascension the scatter is reduced, but there is a systematic shift from the 85·5 Mc./s. position; similar shifts have also been found in the observations of 03*S*3*A* and 12*N*1*A*. Since we believe that any aerial collimation error is much smaller than this, the results suggest that there were large density gradients (density increasing to the east) in the *F*-region which were not reflected in $f0F2$. These gradients must have occurred above the level of maximum ionization density, and were presumably associated with the early morning conditions under which most of the observations were taken.

A more detailed account of these and other experimental results is being prepared for publication.

LETTERS TO THE EDITORS

GENETICS

Salmonella–Escherichia Hybrids

UNTIL recently, genetical studies with *Salmonella typhimurium* have been carried out mainly by the transduction method. In an effort to facilitate such studies, we attempted to develop a means of applying conjugation techniques also, using *S. typhimurium* and *Escherichia coli*, since Baron and his collaborators[1] had been able to produce hybrids between these two bacteria. We have been successful in experiments with a *Salmonella* culture carrying a mutator gene (*mut*) and a culture of *E. coli* strain *K*-12 carrying the factor for high frequency of recombination (*Hfr*). The mutator strain was isolated by Miyake[2] from strain *LT*-7. Its main characteristic is a 10- to 100-fold increase in spontaneous mutability.

Our procedure for the detection of recombinants is as follows. Equal volumes of over-night broth cultures of the *S. typhimurium mut* strain and *E. coli Hfr* are mixed; 0·1-ml. samples of the mixture are plated immediately on appropriate medium; and the plates are incubated for 24–36 hr. at 37° C. Under these conditions the frequency of recombinants is about 1 per 10^6 plated bacteria. Thus it is considerably lower than the frequency observed in recombination between two strains of *E. coli*.

Two *E. coli* strains have been used so far: *HfrCS*101 and *HfrC*. With the first we obtained hybrids in which the following *S. typhimurium* mutant genes were replaced by their wild-type alleles from the *E. coli* genome: ability to ferment lactose (*lac*); requirements for leucine (*leu*), arginine (*arg*), threonine (*thr*), aspartic acid (*asa*), thiamine (*thi*), proline (*pro*), glutamic acid (*glt*) and pantothenate (*pan*). With *HfrC* we have obtained hybrids incorporating the *lac, pro, leu* and *thr* wild-type alleles.

Thus it appears likely that the hybrids may carry any region of chromosome of the donor bacterium.

The results so far can be summarized as follows:

(1) Hybrids have been obtained which combine certain genetic markers carried separately by the two parent bacterial strains.

(2) Among these hybrids three types have been recognized: (*a*) sensitive to virulent *Salmonella* phage *H*5, but resistant to *E. coli* phage *T*6; agglutinated by *Salmonella* serum; (*b*) resistant to phages *H*5 and *T*6; very slight or no agglutination by *Salmonella* serum; (*c*) resistant to phage *H*5, but sensitive to *T*6; not agglutinated by *Salmonella* serum.

(3) Temperate *Salmonella* phage (*PLT*-22 *H*1) grown on a type-(*a*) hybrid will transduce markers carried in the *Salmonella* part of the chromosomal complex, provided the recipient *Salmonella* bacteria have the *mut* (mutator) gene.

(4) This same phage forms about 10^1–10^2 times more plaques on hybrid-(*a*) bacteria than on *LT*-7 bacteria carrying the *mut* gene, and 10^2–10^4 times more plaques than on *LT*-7 bacteria without *mut*. Adsorption tests indicate no difference between hybrid *LT*-7 *mut* and *LT*-7 mut^+ bacteria with regard to phage adsorption.

(5) The approximate order of certain loci in the *Salmonella* genome as determined by these recombination tests is: *mut—thr—leu—pan—pro—lac*. There is evidence that *pro* and *lac* are close together and close also to *asa, glt* and *arg*.

A Further Example of the Kell Blood Group Phenotype K−,k−,Kp(a−b−)

IN an earlier communication[1], we reported two sisters having the Kell phenotype K−,k−,Kp(a−b−). The parents were second cousins, and it was assumed that the sisters were homozygous for a Kell gene the product of which does not react with any of the known Kell antisera. Allen *et al.*[2] later gave this gene the abbreviation K^0. Alternatively, there may be a deletion or suppression. We have sought for other examples of this phenotype by using the serum of the propositus of the above family by the capillary–papain method[3]; by this method the serum reacts with all K+ or k+ bloods. The 3,122nd blood so tested did not react, indicating that it was of the phenotype we sought. This was confirmed by testing with anti-K, anti-k, anti-Kp^a and anti-kp^b; it reacted with none of these.

The parents of the propositus, Mrs. Kan, are first cousins. Her husband, two children, daughter-in-law and four grandchildren are all K−,k+,Kp(a−b+). While the two children are presumably of genotype $kKp^b.K^0$, titration with anti-k and with anti-Kp^b failed to differentiate between assumed genotypes $kKp^b.kKp^b$ and $kKp^b.K^0$. The family is of Finnish descent. The mother and six brothers and sisters of the propositus live in Finland.

It may or may not be significant that two members of the original family in which K^0 occurred, and two of the nine members examined in the present sibship, had suffered abnormal bleeding for which they were transfused; further, the new-born baby of the propositus in the first family suffered from a form of erythroblastosis fœtalis in which petechial hæmorrhages of the skin were a prominent sign.

BIOLOGY

The River Niger as a Barrier in the Spread Eastwards of Hæmoglobin C : a Survey of Hæmoglobins in the Ibo

HÆMOGLOBIN C is associated with West Africa rather than with Africa as a whole. It differs in that respect from hæmoglobin S, which is distributed throughout that continent south of the Sahara and north of the River Zambezi. Within West Africa the highest incidences are found in northern Ghana, where Dagomba, Moshie and Dagarti were seen to include 28, 22, and 16·5 per cent, respectively, of people with hæmoglobin C (ref. 1). Similar high incidences were found in the French territories bordering northern Ghana[2]. East of Ghana hæmoglobin C is still found at an appreciable incidence as far as Western Nigeria in the Yoruba. Thus Allison[3] saw hæmoglobin C in 6 per cent of 104 Yoruba resident in Ghana, and Walters and Lehmann[4] in 7 per cent of 940 inhabitants of a Yoruba village 40 miles north-east of Lagos. Garlick and Barnicot[5] examined 305 Yoruba school-children in Ibadan and found hæmoglobin C in 6·5 per cent.

Though isolated examples of hæmoglobin C have been reported from areas farther east than western Nigeria, surveys have generally failed to show it at an appreciable incidence anywhere east of the River Niger. Walters and Lehmann[4] found no hæmoglobin C in 155 Igalla, a tribe closely related to the Yoruba but differing from them by having remained east of the River Niger in the course of the migration which carried Yoruba and Igalla first from the Sudan to the Bornu Province and later to their present homes. The difference in the genetic make-up of Yoruba and Igalla was attributed to the fact that by crossing the River Niger (Fig. 1) and by invading the coastal forest belt the Yoruba had become involved in warfare with tribes from Dahomy and Ghana to the west, and that raids and counter-raids must have resulted in interchange of captives which would have introduced hæmoglobin C into the Yoruba. The Igalla live in an area lying in the angle formed by the Niger in the west and its main tributary, the Benue, to the north. Hæmoglobin C has also been sought for in the Lake Chad area in the extreme north-east of Nigeria, when Roberts and Lehmann[6] found no hæmoglobin C in 105 Shuva, 116 Kanouri and 92 Bedduwa, but 6 carriers of hæmoglobin C trait among 104 Wakura. South of this region, Langouillon and Delas[7] failed to find hæmoglobin C in an extended survey, with one exception, where 224 Southern Cameroon Bantu included 1 carrier of the hæmoglobin C trait. In all these surveys hæmoglobin S was found at high frequency.

As it seems that hæmoglobin C falls sharply in frequency from west to east within Nigeria, it was of special interest to determine the incidence of this hæmoglobin in people east of the Yoruba, where about 7 per cent are carriers of hæmoglobin C trait. The most important eastern neighbours of the Yoruba are the Ibo, whose administrative headquarters are in Enugu in Eastern Nigeria. Though most of the Ibo live east of the River Niger, some of them are found west of the river—'the Western Ibo'. Edington and Lehmann[1] noted hæmoglobin C among the Ibo resident in Accra, and Allison[3] examined 51 Ibo resident in Ghana and found 3 carriers of hæmoglobin C trait among them. This sample, however, is small, and as the Ibo lived in Ghana it was possible that there had been some local admixture. An undoubted case of hæmoglobin C disease in an Ibo has been seen in Enugu by Nwokolo[8].

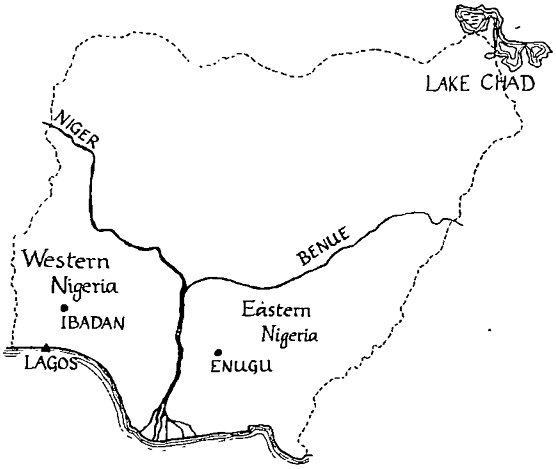

Fig. 1

We examined 257 non-related Ibo, of whom 4 came from west of the River Niger (Western Ibo) and 253 from areas in Eastern Nigeria. 36 were women-teachers attending a training college in Enugu, 17 were nurses at the Enugu General Hospital, 70 were out-patients at a leper hospital in Uzuakoli, and 134 were school-children. Of the school-children, 18 were seen in Lagos and are included in this survey by the kind permission of Dr. W. dos Santos, senior pathologist, Federal Government Medical Services, Nigeria, and the remainder at three different schools in Enugu.

The total number of school-children examined in this survey was 260, but these included non-Ibo: 108 Yoruba and the rest Ibibio, Effik and others. An interesting chance finding was the sickle-cell thalassæmia pattern (S + A + F) in one of the non-Ibo school-children examined. The child came from Benin and the family was resident in Ishan. It is of interest that Benin was exposed to a sustained Portuguese influence in the past, and the finding of thalassæmia in a child coming from Benin might indicate how the classical thalassæmia gene—which is only occasionally discovered in Africa—might have entered that continent.

Table 1. HÆMOGLOBINS IN 257 NON-RELATED IBO

Phenotype	AA	AS	AC	AG
Number	190	64	2	1

Except for the Yoruba, hæmoglobin C was only seen among the Ibo and, as Table 1 shows, there were 2 carriers of the hæmoglobin C trait among the 257 examined. The incidence of 24·9 per cent sickle-cell trait carriers among the Ibo is similar to that in the neighbouring communities of West Africa, and the finding of hæmoglobin G in one Ibo is the first example of this hæmoglobin in Eastern Nigeria. The sharp fall in the incidence of hæmoglobin C from 7 per cent in the Yoruba to less than 1 per cent farther east in the Ibo suggests that the River Niger has acted as a barrier to the spread of hæmoglobin C towards the east. The influence of that river on the distribution of hæmoglobin C is not unlike that of the river Zambezi on the distribution of hæmoglobin S.

We thank Dr. J. U. Ekpo, Enugu, and Dr. C. K. Manuel for their help with the examination of the school-children in Enugu, and Mr. E. S. Drewett for arranging the survey at the Uzuakoli Leper Settle-

ment. One of us (H. L.) would like to thank the Federal and Eastern Region Governments, Nigeria, for defraying the cost of his visit to Nigeria.

Interaction between Ants on a Scent Trail

IT is well known that many ants lay scent trails on the ground which can be followed by other ants[1-3]. When an ant is following such a trail it is guided primarily by the scent 'marks', although other orientating factors, including visual stimuli, are sometimes also involved[2,4]. Carthy[3] has suggested that another factor contributing to the dense trails formed by *Acanthomyops fuliginosus* workers might be a tendency for workers to seek maximal contact with their companions. During a study of the trail systems of the ant *Monomorium pharaonis*[4] it was possible to record the behaviour of successive workers arriving at a branch in the trail system, and to relate this to the behaviour of the preceding ant. At such a branch each ant took either branch A or branch B, and if the proportion of all ants which took branch A was p, the proportion which took B would be $(1 - p)$. If there were no relation between the 'choice' of one ant and that of the following ant the expected proportions of pairs of successive ants taking respectively A and A, A and B, B and A and B and B would be p^2, $p(1 - p)$, $p(1 - p)$ and $(1 - p)^2$. Table 1 shows that the observed proportions conform very closely with these figures and do not differ from them significantly in a χ^2 test ($\chi^2 = 2{\cdot}02$ with 3 degrees of freedom, $P >$ 50 per cent).

Table 1. RELATION BETWEEN THE 'CHOICE' MADE BY ONE ANT BETWEEN TWO TRAILS *A* AND *B* AND THE 'CHOICE' MADE BY THE FOLLOWING ANT. FIGURES FOR ALL ANTS

Choice of first ant	*A*		*B*		Totals		
Choice of second ant	*A*	*B*	*A*	*B*	*A*	*B*	All
Observed numbers	48	63	64	58	112	121	233
Expected numbers	52·9	58·1	58·1	63·9			(233)
Contribution to χ^2	0·45	0·43	0·60	0·54			2·02

As the trails of *Monomorium pharaonis* are not very dense this result is not surprising. *M. pharaonis* were not, however, evenly distributed along the trails, but often ran close behind one another, perhaps simply because quicker ants caught up slower ones. When only such pairs of ants running almost if not quite in contact are considered, both ants of the pair took the same branch of the trail significantly more often than would have been expected if no interaction took place (Table 2, $\chi^2 = 6{\cdot}16$ with 1 degree of freedom, P lies between 1 and 2 per cent). In Table 2 different grouping of the results was necessary because of the smaller numbers involved, but the method by which the expected distribution was calculated was the same as in Table 1. As well as the sixteen pairs on which Table 2 was based there were four groups of three ants and one of seven ants, but such small numbers do not allow any conclusions to be drawn.

Table 2. RELATION BETWEEN THE 'CHOICE' MADE BY ONE ANT AND THAT OF THE FOLLOWING ANT. FIGURES ONLY FOR THOSE ANTS RUNNING IN PAIRS

	Chose the same branch	Chose different branches	Total
Observed number	13	3	16
Expected number	8·03	7·97	16
Contribution to χ^2	3·07	3·09	6·16

Apparently in *Monomorium pharaonis* one ant does tend to follow the course taken by another provided that the two are running so close together as to be almost in contact. According to Hingston[5] *Camponotus sericeus* and *C. paria* behave in a similar way. These ants, however, do not lay scent trails and the recruits reach newly discovered food by following its discoverer on the latter's return to the food from the nest. It seems possible that the trail-laying behaviour of Myrmicine ants has evolved through such a stage where one ant led another directly, and it is therefore interesting to find traces of such behaviour in *Monomorium pharaonis*.

Mechanical Transmission of Cassava Brown Streak Virus

BROWN streak virus disease of cassava (*Manihot utilissima* Pohl.) is important in all the cassava-growing areas on the coasts of Kenya and Tanganyika, because necrosis of the starch storage tissues of the roots and stems of infected plants results in serious losses in yield[1,2]. Transmission of the virus by a white fly (*Bemisia* sp.) is suspected but has not been confirmed[3] and the only reliable means of transmitting it experimentally has been by grafting. The symptoms of the disease vary greatly with variety and environmental conditions, making diagnosis difficult, particularly when plants are infected both with brown streak and cassava mosaic, another virus disease. Thus a major difficulty in studying brown streak has so far been the lack of a means of transmitting the causal virus readily and also uncontaminated with cassava mosaic virus.

A virus causing typical brown streak symptoms in cassava seedlings has now been transmitted mechanically from cassava to several solanaceous plants. Mature leaves from infected cassava plants were macerated in water with alumina powder and 'Celite' and the extract inoculated by rubbing on the leaves of various test plants. Using this method, virus was readily transmitted to susceptible test plants, but similar extracts from young leaves gave no infections.

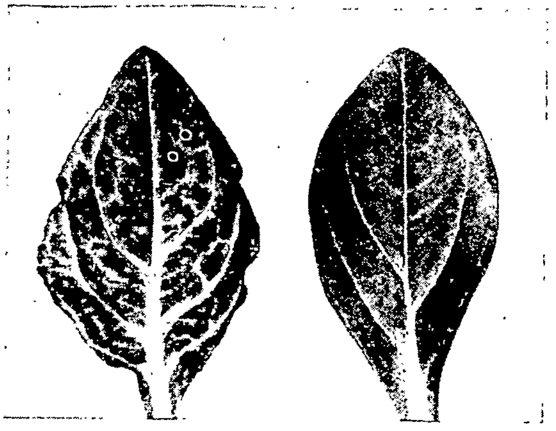

Fig. 1. Leaf of infected *Petunia* (left) with healthy leaf for comparison

Infected *Petunia hybrida* Vilm. plants were stunted and their leaves showed vein chlorosis and necrosis and were crinkled (Fig. 1). In *Datura stramonium* L. a systemic chlorosis of the fine veins developed in summer but only necrotic local lesions in inoculated leaves in winter. Inoculated tobacco (*Nicotiana tabacum* L.) leaves developed only local necrotic lesions but leaves of infected *N. rustica* L. and *N. glutinosa* L. plants showed a mild systemic vein-chlorosis. Cassava seedlings were infected by rubbing both with extracts from infected cassava and *Petunia* plants and showed symptoms consisting of a range of chlorotic patterns on the leaves similar to those described by Storey[1] and Nichols[2]. The characteristic sepia-coloured necrosis developed in the roots of some plants (Fig. 2). Though some of the cassava source-plants were infected with cassava mosaic virus, there was no indication that this was transmitted to any host by the method used.

Petunia was the most susceptible host plant found and it was used in studies on the properties of the virus. In infective *Petunia* sap cassava brown streak was rather unstable with a longevity *in vitro* of less than 24 hr. at 20° C. The infectivity of sap was drastically reduced after heating for 10 min. at 50° C. and abolished by diluting 1 : 1,000 with water. Further studies on the properties of the virus are in progress; meanwhile the development of this rapid and certain method of transmission should aid in diagnosis and in the indexing of cassava varieties for the resistance to the virus which has been reported by workers in East Africa[3,4].

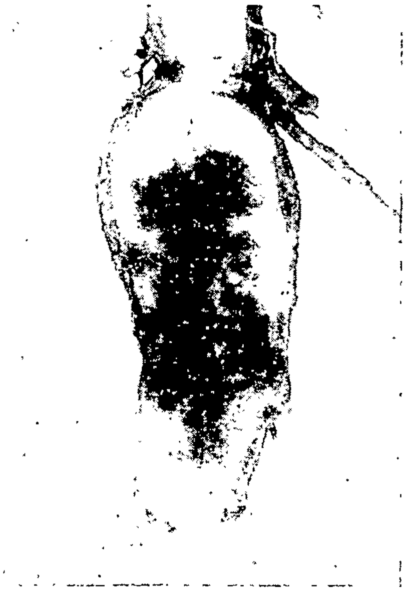

Fig. 2. Section of root of cassava seedling infected with virus from *Petunia*

Thanks are due to Mr. D. L. Jennings, now of this Institute, for obtaining the infected cassava source-plants and to Dr. H. H. Storey, of the East African Agriculture and Forestry Research Organization, for his co-operation and interest.

Serum Transferrins

Genetically controlled variations in the β-globulins of normal human and cattle sera have recently been demonstrated by starch-gel electrophoresis[1-6]. Evidence has been presented[7] suggesting that the variable β-globulins in man are iron-binding serum proteins (transferrins). We have confirmed this directly by demonstrating with autoradiographs that iron-59 is bound specifically to the variable β-globulins in human sera, and also in cattle sera. The variable serum β-globulins in man and cattle are thus transferrins.

The results of an experiment to demonstrate the iron-binding properties of the variable serum β-globulins in humans are presented in Fig. 1. Approximately 2 μgm. of iron (containing 5 μc. iron-59) were added, as ferrous sulphate, to each ml. of serum; 0·05 ml. samples of the sera containing iron-59 (from 5 individuals) were subjected to vertical starch-gel electrophoresis[8]. The gel was cut into two slices. One slice was stained for protein (left-hand photograph in the figure); the other was used to make an autoradiograph (right-hand photograph in the figure) by placing the gel slice, wrapped in non-porous transparent film ('Saran Wrap', Dow Chemical Corporation), in contact with Kodak 'No-screen' X-ray film for 12 hr. The film was developed for 3 min. at 20° C. in Kodak formula *D*8 developer. The iron-59 is clearly bound to the variable β-globulins (indicated in the figure by white dots), which demonstrates that these proteins are transferrins. The faster migrating transferrin in each serum appears to bind relatively more iron-59 than the slower transferrin. The diffuse area of radioactivity near the sample insertion positions of some of the sera was due to the addition of more iron than could be bound by the transferrins, leading to the precipitation of inorganic iron in the gel. Addition of more serum (not containing added iron) to these samples caused the radioactivity to be confined entirely to the transferrins.

Only one transferrin (*C*) is present in the serum of the majority of individuals in all racial groups yet studied; such persons are thought to be homozygous for the genes corresponding to transferrin *C*. Two transferrins can be detected in the serum of individuals

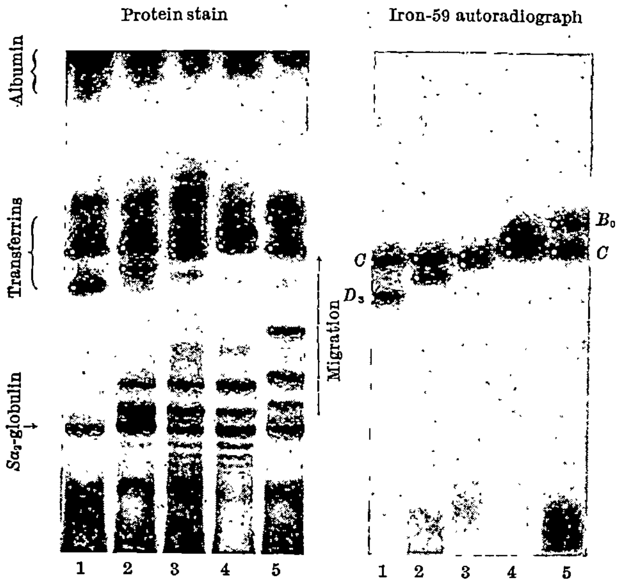

Fig. 1. The results of a vertical starch-gel electrophoresis (ref. 8) experiment with five sera containing iron-59 (plus hæmoglobin) from human individuals presumed to be heterozygous for transferrin genes. The left-hand photograph shows the protein-stained gel slice (from the sample slots to the albumin). The right-hand photograph shows the autoradiograph obtained with a second slice from the same gel. The diffuse patches of iron-59 near the sample slots are due to precipitated inorganic iron. The sera from left to right were of transferrin types (see text): 1, CD_3; 2, CD_1; 3, CD_0; 4, B_2C; 5, B_0C. The transferrin zones are indicated in the figure by white dots

who are heterozygous for transferrin genes[2-4,7]. The five sera used for the experiment illustrated were all from individuals presumed to be heterozygous for genes corresponding to transferrin C and to an additional transferrin (different in each of these five persons); three of the transferrin types illustrated (1, 3 and 5) have not been previously described:

Serum 1; *transferrin type* CD_3. Serum of this 'new' transferrin type, provisionally designated CD_3, was observed in 1 of 493 American negroes from Seattle (H. Harris, personal communication, has recently encountered a serum of the same type). Transferrin D_3 migrates in starch gels more slowly than any transferrin previously reported.

Serum 2; *transferrin type* CD_1. This serum was from an Australian aborigine. Sera of the same transferrin type, originally referred to as β-globulin type CD by Horsfall and Smithies[2], have been observed in approximately 10 per cent of Australian aborigines[2,7] and American negroes (E. R. Giblett and J. Chase, unpublished data). Comparison of a serum of transferrin type CD_1 with serum of the β-globulin type CD_1 of Harris, Robson and Siniscalco[4] indicates their equivalence. Harris *et al.* observed 3 sera of this type in 153 from Gambian negroes.

Serum 3; *transferrin type* CD_0. This 'new' type, provisionally designated CD_0, was observed in 1 of 493 sera from American negroes.

Serum 4; *transferrin type* B_2C. Serum of this transferrin type, originally referred to as β-globulin type BC by Smithies[3], has been identified with the type B_2C since reported by Harris *et al.*[4]. Sera of transferrin type B_2C were observed in 5 of 425 Canadian whites[3], and in 1 of 139 British whites[4].

Serum 5; *transferrin type* B_0C. This 'new' transferrin type was observed in 1 of 100 sera from American whites. Transferrin B_0 migrates in starch gels more rapidly than any transferrin previously observed.

Sera of two other heterozygous transferrin types (B_1C and CD_2) previously described[4] were not available at the time of this experiment. However, transferrin B_1, observed in 1 of 139 sera from British whites, migrates in the gels less rapidly than transferrin B_0 but more rapidly than transferrin B_2; transferrin D_2, observed in 1 of 153 sera from Gambian negroes, migrates less rapidly than transferrin D_1 but more rapidly than transferrin D_3 (Harris and Smithies, unpublished work). Thus 8 transferrins (B_0, B_1, B_2, C, D_0, D_1, D_2 and D_3) have now been observed in man.

It is interesting that transferrins which migrate less rapidly than transferrin C have not been reported in whites, and transferrins migrating more rapidly than transferrin C have not been observed in negroes (with the exception of one serum of transferrin type B_2C in 493 from American negroes).

Estimation of the Size of Antigens by Gel Diffusion Methods

ANALYSIS of the pattern of precipitation lines formed when antigens and antibodies diffuse towards one another in an agar gel is established as a valuable qualitative technique in immunology. In the systems commonly used, diffusion occurs either in a tube[1] or in a flat sheet of gel[2]. Several theoretical treatments of the tube-diffusion system have been presented[3]. In the latest, and most satisfactory, by Augustin *et al.*[4], a formula is given for calculation of the approximate diffusion coefficients of antigens from accurate measurements of the position of the precipitin lines at various intervals of time. Great accuracy is not claimed for the method, however, and it is difficult to apply when several antigens are present. Korngold and van Leeuwen[5] have given a theoretical treatment for systems where diffusion occurs in a flat sheet, which enabled them to deduce that the precipitation line would be convex towards the well containing the reacting material with the greater diffusion constant. Although this conclusion is valid, the equations derived are not suitable for calculation of accurate diffusion coefficients because they depend on the assumption, which we have found to be invalid, that free diffusion continues after precipitation has begun.

Two other systems have proved satisfactory in practice.

(1) Antigen and antibody are placed in troughs cut at 90° in a uniform layer of agar on a flat glass plate. This arrangement resembles that suggested by Elek[2], who showed that in such a system precipita-

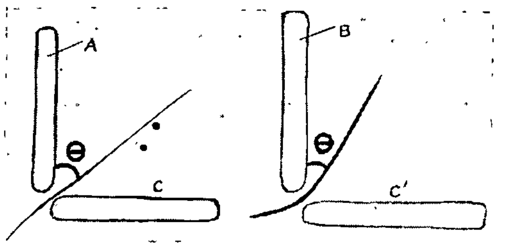

Fig. 1. Photographs of stained precipitation lines obtained by diffusion of antigen and antibody in agar gel from wells at right-angles to one another. *A*, Human serum transferrin, θ = 51°; *B*, human serum β-lipoprotein, θ = 28°; *C*, *C′* corresponding antisera

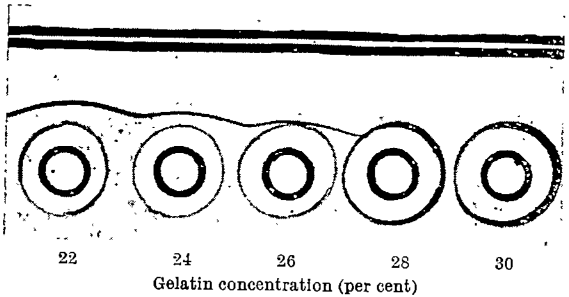

Fig. 2. Limitation of passage of human serum albumin through gelatin gels of increasing concentration

tion occurs at optimal proportions along a plane which, viewed from above, appears as a line. It can be shown that, when the amounts of antigen and antibody in the troughs are such as to give optimum proportions, precipitation will occur along a straight line inclined at an angle θ° to the antigen trough, such that $\tan\theta = (D_g/D_b)^{1/2}$, where D_g and D_b are diffusion coefficients of antigen and antibody respectively. This relationship holds true even though free diffusion is disturbed by precipitation of the reagents, but a truly straight line is formed only when the proportions of antigen and antibody in the troughs are correct. In practice, narrow straight precipitation lines are obtained within quite a wide range of relative concentrations; but when the proportions are grossly incorrect, a diffuse curved precipitate band is formed which spreads towards the trough containing the weaker reagent. Different antigen–antibody systems are precipitated independently of one another or of inert proteins present, and the diffusion coefficient of each component in a mixture can be measured, provided that the relative proportions of antigen and antibody are adjusted to be about optimal for each antigen–antibody system. Photographs of precipitate lines obtained with two representative antigens differing widely in molecular weight are shown in Fig 1. The angles of the lines are measured to within ½° on a 10 × magnified image projected on to a ground-glass screen. In Table 1 are summarized the diffusion coefficients calculated for a range of test antigens by this method, with reference to rabbit antibody, the diffusion coefficient of which was taken[5] as $3\cdot8 \times 10^{-7}$ cm.^{2} sec.$^{-1}$. The agreement with the values obtained by conventional techniques is good. These values are taken from the following sources: hen's ovalbumin, human serum albumin, human γ-globulin (Kabat, E. A., and Mayer, M. M. "Experimental Immunochemistry", C. C. Thomas, Springfield, Ill., 1948); human serum transferrin (Schultze, H. E., Heide, K., and Müller, H., *Behringwerk-Mitt.*, No. 31, 24; 1957); rat liver catalase (Price, V. E., and Greenfield, R. E., *J. Biol. Chem.*, 209, 363; 1954); sheep thyroglobulin (O'Donnell, I. J., Baldwin, R. L., and Williams, J. W., *Biochim. Biophys. Acta*, 28, 294; 1957); human serum β-lipoprotein (Levine, L., Kauffman, D. L., and Brown, R. K., *J. Exp. Med.*, 102, 105; 1955); mouse γ-globulin (Nathans, D., Fahey, J. L., and Potter, M., *J. Exp. Med.*, 108, 121; 1958, and unpublished observations); mouse urinary protein (unpublished measurements by Dr. P. C. Charlwood).

(2) An alternative technique depends upon the 'molecular sieve' properties of agar and gelatin gels, in which the size of the 'pores' or spaces within the solid phase becomes smaller as the concentration of solid increases. Polson[6] has presented evidence that penetration of proteins into agar gels is limited by their size (Table 2). We have studied agar, which forms suitable gels at concentrations of 1–7 per cent (w/v), and gelatin, which can be used at concentrations of 4–40 per cent (w/v). A convenient technique is shown in Fig. 2. A layer of 1·5 per cent agar (depth 2 mm.) is poured on a flat glass plate 10 cm. × 10 cm., and, after setting, holes are cut out with a cork borer. The holes are filled with molten gelatin or agar solutions of varying concentration (gelatin dissolved by heating in $M/15$ phosphate buffer pH 7·0 at 60°, and agar at 100°). When these plugs have set, holes with 3–4 mm. smaller diameter are cut out from the centres and sealed, leaving hollow cylinders of concentrated gelatin or agar. A narrow trough for antiserum is cut 7–8 mm. from the cylinders, and the plate is set aside for 24 hr. at room temperature for the gelatin to 'mature'. Antigen is then placed inside the cylinders and antiserum in the trough. After 1–2 days, lines of precipitate appear in the agar near those cylinders through which sufficient antigen has diffused, and lines due to common antigens fuse together. When the concentration of gel in the cylinder is high enough to prevent significant passage of antigen, no line is formed in the agar, and the line from the neighbouring cylinder appears to pass into the cylinder in question (Fig. 2). This is taken as the end-point, and is readily reproducible over a wide range of concentration of antigen and antibody. In mixtures of antigens, each reaches its end-point independently. Some results with reference antigens are given in Table 3. The technique permits estimation of the order of the effective size of antigens to within ± 30 per cent. Thus ovalbumin (mol. wt.

Table 1. DIFFUSION COEFFICIENTS (× 10^{-7} CM.^{2} SEC.$^{-1}$) OF ANTIGENS CALCULATED FROM AGAR PRECIPITATION LINES AND AS MEASURED BY OTHER TECHNIQUES

Protein	θ	Calculated D_{20}	Reported D_{20}	Molecular weight
Mouse urinary protein	58°	9·6	9·7	17,000
Hen's ovalbumin	54°	7·1	7·7	43,800
Human serum albumin	52°	6·1	6·1	70,000
Human serum transferrin	51°	5·7	5·8	88,000
Human γ-globulin	45°	3·8	3·6	177,000
Mouse γ-globulin	45°	3·8	3·9	160,000
Rat liver catalase	45°	3·8	4·1	249,000
Sheep thyroglobulin	38°	2·3	2·6	660,000
Human serum β-lipoprotein	28°	1·1	0·98	2,770,000

Table 2. PERCENTAGES (W/V) OF AGAR-LIMITING PENETRATION OF ANTIGENS

Protein	Estimated molecular weight	Concentration of agar
Caminella hæmocyanin	6,600,000	3 (ref. 6)
Human serum β-lipoprotein	2,770,000	5
Sheep thyroglobulin	660,000	7
Jasus hæmocyanin	450,000	7 (ref. 6)

Table 3. PERCENTAGES (W/V) OF GELATIN-LIMITING PENETRATION OF ANTIGENS

Protein	Estimated molecular weight	Concentration of gelatin
Human serum β-lipoprotein	2,770,000	5
Sheep thyroglobulin	660,000	7
Human and rat serum γ-globulin	177,000	18
Human serum transferrin	88,000	26
Human serum albumin	70,000	28
Hen's ovalbumin	44,000	32
Mouse urinary protein	17,000	>40

44,000) is consistently distinguished from human serum albumin (mol. wt. 70,000).

These two methods have already proved useful in estimating the size of virus antigens. Their advantage lies in the fact that values for diffusion coefficients or size of components of a mixture of antigens can be obtained at an early stage of purification. Further details and a theoretical analysis of the diffusion systems used will be submitted for publication in *Immunology*.

We are indebted to Mr. A. G. Ward, of the British Gelatin and Glue Research Association, for supplies of high-grade gelatin, and to Drs. P. G. H. Gell, T. S. Work and B. A. Askonas for gifts of β-lipoprotein, catalase and thyroglobulin, and antisera against them.

Electron Microscopy of Synaptic Contacts on Dendrite Spines of the Cerebral Cortex

WHEN stained by the Golgi or methylene-blue method for light microscopy, certain dendrites of the cerebral cortex and elsewhere appear to have numerous spinous projections[1]. The nature of these spines has long been disputed. For example, it has been suggested that they are simply 'nutritive' expansions, or pre-synaptic end-feet, or post-synaptic processes of the dendrite—the pre-synaptic component remaining unstained[1-3]. Electron microscopy shows that the spines are in fact sites of synaptic contact.

The rat visual cortex was fixed with buffered osmium tetroxide, 'stained' with alcoholic phosphotungstic acid and embedded in araldite for sectioning[4].

Dendrites, which can be identified by their tubules[4,5], are often seen to have spinous projections. A spine (Fig. 1) is 2μ or less long and its stalk (*b*) may be as narrow as 0·1μ. The dendrite tubules (*den. t.*) are absent from the spine, which, however, frequently contains granular material. A structure, here termed the spine apparatus (*a*), often appears in the spine cytoplasm. It consists of two, three or more clear spaces (profiles of sacs, vesicles or continuous channels ?) and between each pair of opposed membranes of these 'sacs' a dense line occurs. No function can be ascribed to the spine apparatus at present. So far it has not been observed in the cytoplasm of the dendrite trunk or perikaryon.

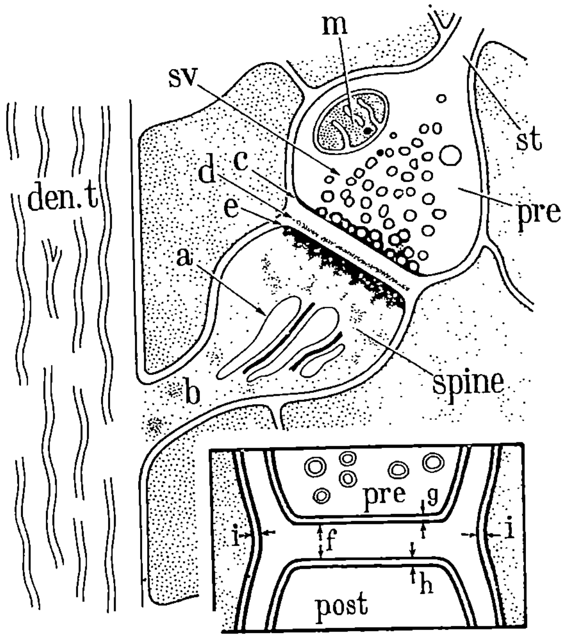

Fig. 1. Diagram of a synaptic contact on a dendritic spine, observed with the electron microscope after osmium tetroxide fixation. The stippled regions represent neuronal and glial processes of the neuropil

Inset. The opposed regions of the pre- and post-synaptic membranes seen after potassium permanganate fixation. The membranes (*i*) are of neighbouring processes of the neuropil

A pre-synaptic process (Fig. 1, *pre*) contacts the tip of the spine. The end-foot is commonly about 1μ in diameter and its stalk (*st*) (pre-terminal axon) is commonly 0·2–0·3μ in diameter. The synaptic relationship is similar to that described previously[4] for synapses formed directly with dendrite trunks. These have been termed type 1. Type 2 synapses (similar to those found elsewhere in the central nervous system) occur only on dendrite trunks and perikarya[4].

Briefly, a section of the pre-synaptic process contains usually one mitochondrion (*m*) and numerous synaptic vesicles (*sv*). Some lie in contact with the pre-synaptic membrane (*c*). Those nearest the membrane often appear denser. The pre-synaptic and post-synaptic membranes (*c* and *e*) lie 250–300 A. apart and in the extra-cellular region between them a band of electron-scattering material (*d*) occurs, sometimes slightly nearer the post- than the pre-synaptic membrane. Dense material appears associated with the cytoplasmic surface of the post-synaptic (spine) membrane (*e*). The pre-synaptic membrane (*c*), where it is opposed to the post-synaptic membrane, usually appears denser and sometimes thicker than elsewhere.

For comparison with this picture after osmium fixation the synaptic membranes have also been observed after fixation with potassium permanganate (Fig. 1, inset). Robertson[6] has described the unit membrane configuration present at cell surfaces and interpreted it in terms of organized lipid molecules. I confirm that the unit membrane structure is characteristic of cell processes of the cerebral cortex. The pre- and post-synaptic membranes (between arrows *g* and *h*) show the unit membrane consisting of two parallel dense lines, each ~ 20 A. thick, and a clear intervening layer ~ 30 A. thick. The measurement of the gap between pre- and post-synaptic processes (*f*) is consistent with the osmium picture in that the zone between the opposed pre- and post-synaptic membranes is wider than the zones between non-synaptic processes[4]. The dense band (*d*, Fig. 1) does not appear in permanganate preparations. It appears to be extracellular material and not the middle line of an external compound membrane[6], since the line occurs when the gap between membranes is closed; in this case the gap is wider than that between opposed non-synaptic processes.

In permanganate preparations (Fig. 1, inset) the dense material associated particularly with the post-synaptic membrane does not appear: nor do the synaptic vesicles nearest the pre-synaptic membrane appear denser.

The spine seen with the light microscope in suitable preparations can thus be identified with the electron microscope. The pre-synaptic end-feet, only just visible by light microscopy[7], can also readily be seen. Similar end-feet (type 1) are common on the dendrite trunks but not neuron perikarya. A full report will be published elsewhere.

I am indebted to Prof. J. Z. Young and Dr. J. D. Robertson for their interest and advice.

Identity of the Abscission-accelerating Substance in Senescent Leaves

Van Steveninck[1], in a recent communication describing abscission-accelerators from lupins, has suggested a similarity of one of these substances to the abscission-accelerating factor discovered in senescent leaves[2], and attributes to me the statement that the latter substance is not a sugar, amino-acid, purine or pyrimidine. In fact, in the paper in question[3] it is stated that the abscission-accelerator in senescent leaves was "so far unidentified chemically, but does not appear to be any of the more common sugars, amino-acids, purines or pyrimidines".

For clearness, it might be added that using bean explants for the bioassay, and testing a wide range of concentrations, no abscission-accelerating activity has been found for glucose, fructose, sucrose, glycine, aspartic and glutamic acids, L-valine, L-histidine, L-leucine, L-tyrosine, cysteine, methionine, adenine, guanine, xanthine, hypoxanthine or uracil.

PHYSIOLOGY

Ester Sulphate Pattern of Rabbit Bile

Isselbacher and McCarthy[1] have recently reported excretion of a sulphate conjugate of bilirubin in the bile of rats. Using paper chromatography and autoradiography of diazotized bile from rats injected with sulphate labelled with sulphur-35, they demonstrated the presence of a radioactive zone in the area of the polar azo pigment.

A series of systematic screening studies on the ester sulphate pattern of different body fluids has recently been started at our laboratory[2,3]. A brief account is given in the following of some observations made in this connexion on the occurrence of ester sulphates in rabbit bile.

Four adult rabbits with an average weight of 2·5 kgm. were used. Doses of 5–10 mc. of radioactive sulphate were injected into the marginal vein of the ear. The rabbits (which were used for other studies as well) were kept starving in metabolic cages for 24 hr. after the injection. They were then killed by insufflation of air into the ear vein. The gall-bladders were removed, the bile emptied into test-tubes, and kept in the deep-freeze unit until used.

Of the different samples of bile obtained, 5 and 25 μl. were subjected without any pretreatment to two-dimensional paper chromatography according to Datta, Dent and Harris[4]. The following solvents were used: (1) Phenol–water (400 gm. + 100 gm.). A beaker containing concentrated ammonia was placed in the chromatographic tank. (2) Butanol–2 *N* ammonia (250 ml. + 250 ml.).

After drying the papers in a stream of hot air from an electric hair-drying fan, the chromatograms were subjected to autoradiography on Gevaert 'Curix' X-ray film, exposed for one week in a wooden screw-press and developed with *G*150.

Hydrolysing experiments with hydrochloric acid and sodium hydroxide were performed on two of the samples, as follows. To 10-μl. portions of the bile in small test-tubes, 90 μl. of distilled water, 0·1 or 0·5 *N* hydrochloric acid or sodium hydroxide, respectively, were added. The tubes were sealed, and heated in a boiling water-bath for 15, 30 or 60 min. After cooling, the tubes were opened and the solutions evaporated to dryness in an exsiccator. The residues were dissolved in 10 μl. of water, and 5-μl. portions of these solutions were subjected to combined chromato-autoradiography as previously described.

A typical result of this study is presented in Fig. 1. All biles so far investigated showed the same type of pattern of radioactive spots on the autoradiograms. In addition to the occurrence of some radioactivity at the starting point of the chromatogram (1), corresponding to labelled material which did not move in either of the solvents used, and the distinct spot of inorganic sulphate (2), at least six other compounds labelled with sulphur-35 were visualized (201–206). Most of these spots were fairly resistant to alkaline hydrolysis (0·5 *N* sodium hydroxide for 60 min. at 100° C.), since only minor changes in the pattern occurred under these conditions.

Heating in hydrochloric acid, on the other hand, destroyed the whole pattern. Thus, after heating in 0·5 *N* hydrochloric acid for 15 min. at 100° C., all the 201–206 spots vanished, and a marked increase in the inorganic sulphate spot took place.

Although none of the 201–206 spots has as yet been identified, it appears that a fairly large number

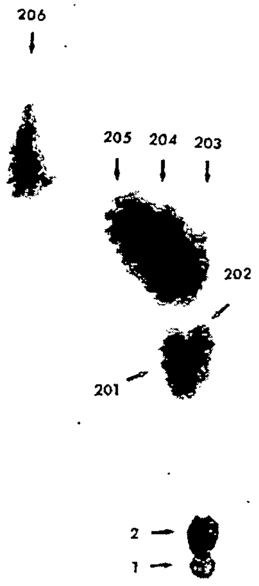

Fig. 1. Chromato-autoradiogram of 5 μl. of rabbit bile 24 hr. after injection of radioactive sulphate. Solvents: Phenol–water; butanol–ammonia. 1, Starting point; 2, inorganic sulphate; 201–203, unidentified compounds labelled with sulphur-35

of ester sulphates are excreted in the bile. Since no characteristic differences were found in this respect between the four animals studied under basic conditions, it is suggested that a characteristic, more or less constant ester sulphate pattern exists in rabbit bile.

This study was supported by research grants from the National Institutes of Health, Bethesda (*A*-2568 *M* and *N*), and the Swedish Medical Research Council.

Site and Mode of Trehalose Biosynthesis in the Locust

THE disaccharide trehalose was first identified as an important constituent of insect hæmolymph by Wyatt and Kalf[1] using silkmoth pupæ, and it has since been found in other insect species and in nematodes[2]. Howden and Kilby[3] showed that trehalose may occur in concentrations up to 2 per cent in the hæmolymph of the desert locust, *Schistocerca gregaria* Forsk., and isolated a crystalline sample from this source. Work with the migratory locust, *Locusta migratoria*[4], and the blowfly, *Phormia regina*[5], has shown that the concentration of trehalose falls sharply during flight, and it therefore appears that this sugar is an important soluble carbohydrate and energy reserve in insects. Treherne[6] has shown that radioactive glucose introduced into the gut of *Schistocerca* rapidly gives rise to the appearance of radioactive trehalose in the hæmolymph, but nothing has been known hitherto as to the site or mode of formation of trehalose from glucose.

We have now shown that locust fat body is an important site of trehalose biosynthesis. Generally labelled D-glucose-^{14}C was incubated with fat-body tissue from *Schistocerca* (fifth instar) and the products examined by paper chromatography. A significant radioactive peak was found corresponding to the trehalose spot. Hæmolymph, leg muscle, fore, mid and hind gut tissues were also tested but found to be largely inactive in converting glucose into trehalose. The clear supernatant fraction obtained by centrifugation of an extract of homogenized and freeze-dried fat-body tissue from adult locusts was also active. After dialysis, considerable enhancement of activity was obtained by adding adenosine triphosphate (ATP) and uridine diphosphate glucose (UDPG).

Table 1

Reaction mixture	Counts per min. for trehalose spot	Counts per min. for glucose spot
Dialysed enzyme + glucose + ATP + UDPG	818	18
Dialysed enzyme + glucose + ATP	144	27
Dialysed enzyme + glucose + UDPG	324	358

Small amounts of radioactivity appeared in other peaks, but these products have not yet been identified. In another experiment, the count for the trehalose spot rose from 38 to 953 c.p.m. on adding uridine diphosphate glucose to the system containing adenosine triphosphate.

The identity of the radioactive trehalose was confirmed by the following methods. It was isolated by paper chromatography and eluted, mixed with authentic trehalose and the mixture developed on paper chromatograms using four different solvents. Radioautography of the chromatograms showed that in all cases the radioactive spots were absolutely identical in shape and position with those due to trehalose on the chromatograms, detected by Trevelyan's silver nitrate method[7]. In another experiment, the same mixture was incubated with a trehalase preparation and it was found that the rate of appearance of reducing sugar was closely paralleled by the rate of appearance of radioactive glucose and the corresponding disappearance of radioactive trehalose. The figures in Table 1 show that both adenosine triphosphate and uridine diphosphate glucose are required. In the absence of added adenosine triphosphate, considerable amounts of free glucose remain, while in the absence of uridine diphosphate glucose most of the labelled glucose is converted into products other than trehalose. Since the uridine diphosphate glucose was present in substrate amounts, the requirement for adenosine triphosphate indicates that trehalose biosynthesis occurs through phosphorylated intermediates. Cabib and Leloir[8] have shown that yeast extracts convert glucose-6-phosphate into trehalose phosphate in the presence of uridine diphosphate glucose, and it appears probable that a similar pathway may occur in insects and that the trehalose phosphate formed is hydrolysed by a phosphatase to free trehalose. This point is now being considered.

A full account of this work will be published elsewhere. We are indebted to the Anti-Locust

Research Centre for supplies of locusts and for a research studentship for one of us (D. J. C.).

Iodine-131 Clearance-rates as an Indication of the Blood Supply of Bone

We have described[1] the use of sodium-24 clearance studies in the experimental and clinical determination of bone vascularity. Sodium-24 has a half-life of only 15·06 hr. and in the United States is only available from Oakridge National Laboratory on one day of each week. Thus it is difficult to use it for clinical investigation if more than three half-lives have transpired since its removal from the pile. This led us to search for an isotope with a longer half-life that could be used for clearance studies. Iodine-131 is readily available in most large hospitals, where it is used for the investigation and treatment of thyroid diseases. The half-life of iodine-131 being 8·0 days, it is more suitable for clinical use throughout the week than is the short-lived sodium-24.

Iodine-131 emits beta-radiation of 0·6 MeV. and gamma photons with peaks of 0·367 and 0·080 MeV. These gamma photons can be counted from the body surface and thus the clearance-rate from an injected site can be followed. Douglas and Meneeley[2] have used iodine-131 to measure the blood flow in skin flaps in plastic surgical procedures. The potential clearance of iodine-131 should be greater than that of sodium-24 as the latter must arrive at an equilibrium with the sodium of local tissue fluid; this is not a factor with iodine.

Animal experiments were undertaken to determine the suitability of iodine-131 injected as the sodium salt for clearance studies in dog femoral heads. The procedure used was the same as described previously[1]. A dose of 5 μc. iodine-131 in 0·1 ml. as sodium iodide was used and good readings obtained from the hip joints. The metal syringe previously described was used. With refinements of technique the dose of 50–100 μc. sodium-24 previously used has also been reduced to 5–6 μc. for human use. The results are shown in Fig. 1 for twenty-eight hips in 21 dogs. The same three groups of clearance values emerged as had been found with the sodium-24 clearance studies. Thirteen femoral heads were vascular with clearances of 30·9–72·9 per cent in 10 min. Ten femoral heads were completely devascularized with clearances less than 9 per cent. Two of these showed a slow rise in count of a few per cent, presumably due to diffusion of the iodine-131 through the dead femoral head, thus coming nearer to the surface of the bone during the counting period.

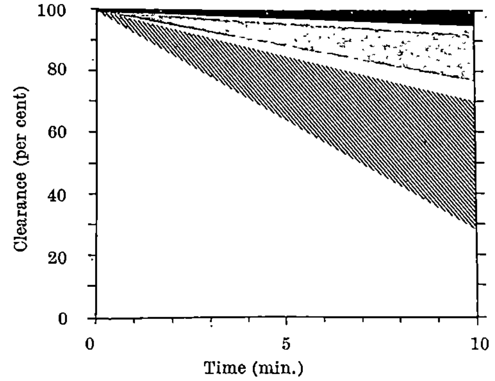

Fig. 1. Diagrammatic presentation of results on iodine-131 clearance of dog femoral heads. Black area shows avascular heads with less than 5 per cent clearance; cross-hatched area shows partially devascularized heads; and the stippled area shows the clearance in normal vascular heads

From these preliminary results there seems no objection to the use of sodium iodide-131 for the determination of the blood supply of bone in human patients. The dose of 5 μc. is small and safe and allows easy surface counting with a scintillation probe containing a 2-in. thorium-activated sodium iodide crystal. Uptake of iodine-131 by the thyroid may be prevented by pre-operative administration of iodides to the patient. Excretion of the injected sodium iodide-131 will then take place rapidly through the kidneys, thus ridding the body of the radioactive salt.

Aqueous Humour of the Hippopotamus

The opportunity recently arose to analyse the eye fluids of the hippopotamus (*Hippopotamus amphibius*). Specimens were chosen for analysis only from animals that had been killed instantaneously, and whose ocular fluids could be removed within a couple of minutes of death. Simultaneously, arterial blood was collected anaerobically from a suitably placed bullet wound. The average volume of fluid in the anterior chamber of the eye was 1 ml.

The fluids were analysed for potassium with a flame photometer, for total carbon dioxide by Conway's microdiffusion method, for chloride by the method of Schales and Schales. Total plasma proteins were estimated by van Slyke's copper sulphate method and corrections for the total solids of the fluids were made, so as to allow the ionic constituents to be expressed as m.moles/kgm. water. The figures in Table 1 were obtained.

The figures for carbon dioxide and chloride are in keeping with those found by Davson and Luck[1] in other animals with eyes of this size and proportion. (Average weight of globe 18·0 ± 1·8 gm. (*S.E.*) average weight of lens 0·95 ± 0·05 gm., from 4 hippopotamuses). The ratios, however, for potassium in the aqueous water/potassium in plasma water are,

Table 1

Animal No.	Aqueous	Plasma	Aqueous/Plasma
Potassium concentrations (m.moles/kgm. water)			
1	5·0	11·9	0·42
2	5·4	9·0	0·60
3	5·2	8·6	0·60
4*	8·5	8·3	1·02
Total carbon dioxide concentrations (m.moles/kgm. water)			
5	34·5	36·5	0·95
6	30·7	37·9	0·81
7	27·3	37·0	0·74
Chloride concentrations (m.moles/kgm. water)			
5	116	112	1·01
6	119	107	1·11
7	128	113	1·13

* This animal's aqueous humour clotted on standing, which only occurs under abnormal conditions of aqueous humour formation, resulting in an increased permeability of the blood–aqueous barrier.

with the exception of the fourth animal in this series, quite different from those found in other species[2].

To ensure that this distribution was not attributable to artefacts in the flame photometric analysis of fluids containing protein (8·7–10·2 gm. protein/100 ml. blood in this species), aqueous humour was dialysed against plasma from the same animal; the ratio after dialysis rose to 0·97.

The further possibility that the ratio is spurious and caused by the delay between collection and centrifuging the blood in the field, with a consequent rise in plasma potassium, is made unlikely by the high concentration of potassium found in the plasmoid aqueous of animal No. 4.

The main interest in this study lies in the observed potassium distribution.

Comparative studies of plasma, aqueous humour and the cerebrospinal fluid in several mammalian species have revealed so many similarities between the ionic composition of the aqueous humour and the cerebrospinal fluid that it has been postulated that the two fluids are formed by closely similar processes[3].

The cerebrospinal fluid varies less from species to species than does the aqueous humour; this depends perhaps on the greater variety of tissues in the eye, compared with that of the central nervous system, and the species variation in the relative size of these different components.

In all mammals hitherto examined, however, there has been one consistent difference in the ionic composition of the two fluids. The cerebrospinal fluid always contains markedly less potassium than the plasma; the ratio concentration of potassium in cerebrospinal fluid water/concentration of potassium in plasma water is of the order[4] of 0·5. The equivalent ratio for the aqueous humour is nearer unity and conforms more closely to the expected ratio for a dialysate of plasma. The ionic distributions, including that of potassium in the hippopotamus's aqueous humour are similar to those of the cerebrospinal fluid in most animals and appear to lend some support to the conception that the two fluids are formed by similar mechanisms.

Why the capacity to restrict the entry of potassium into the aqueous humour should be revealed in this species is a matter for speculation. The phenomenon may, however, be related to the unusually high concentration of potassium in the plasma; it is nearly twice that of most other animals. Davson[3] has postulated that the presence of a low concentration of potassium in the fluid around nerve cells in the central nervous system serves to stabilize the neuronal resting potentials. Perhaps a similar mechanism becomes necessary also in the eye (especially the retina) in the face of an unusually high level of plasma potassium.

We wish to thank the director of the National Parks of Uganda, Mr. R. M. Bere, for permitting and assisting this study.

Iron Content in the Serum of Cows with Hypocupræmia

Disturbances in the health of cattle accompanied by a drop in the copper-level in the blood have been observed in several countries. Sjollema[1] was the first to show that loss of appetite, anæmia, deficiency in milk output, and difficulties in breeding occurred simultaneously with a drop in the copper-level. Hypocupræmia in cattle has been found in certain areas of Poland[2]. Some investigators believe that anæmia does not occur in cases of hypocupræmia[3]. Generally, however, the metabolism of iron and of copper are believed to be interdependent[4]. Lahey *et al.*[5] noticed that the iron content in the plasma of young pigs, which were given no copper in their food, was very low. So far as I know the iron content in the serum of cows with hypocupræmia has not yet been investigated, although the hæmoglobin content has. An apparent decrease in the hæmoglobin and erythrocytes in cattle during hypocupræmia has been noticed in our studies hitherto. It must, however, be admitted that in some cases we found no anæmia.

In the present work the iron content in the serum of cows with hypocupræmia has been determined. I wished to confirm that a drop in the copper-level in the blood influences iron metabolism in cattle. It is assumed that the iron and hæmoglobin contents in the serum are a valid indicator of the iron stock in the organism.

The examinations were performed on the blood of the cattle from individual farms in the districts of Białystok and Olsztyn. In 67 of 120 animals hypocupræmia was found. Copper was determined by the method of Eden and Green[6]. Iron in the serum was determined by the standard photometric method[7]. 45 cows from the Zootechnical Institute were used as a control group. The results are shown in Table 1.

Table 1

No. of cows	Average copper content (mgm. per cent)	Range	Average iron content (mgm. per cent)	Range	Average hæmoglobin content (gm. per cent)	Range
45 (controls)	98·8	79·7–135·0	181	135–215	11·4	8·5–13·3
67	49·7	8·6 75·8	126	86–215	8·2	5·9–10·3

These results obviously indicate that iron metabolism is affected by hypocupræmia. Detailed results will be published elsewhere.

Effect of Protein-free Diet on the Vitamin A Storage in the Rat Liver

SEVERAL workers[1-4] have reported that diets low in protein reduced the storage of vitamin A in the liver and increased the rate at which stored vitamin A was depleted. On the basis of such data, a conclusion was drawn by investigators that protein is a necessary dietary constituent for normal storage and utilization of vitamin A. The work described here was designed to test the validity of the former hypothesis by comparing hepatic vitamin A storage in young rats fed an 18 per cent casein diet and in animals fed a protein-free diet under the conditions of controlled intake of vitamin A.

Six comparable pairs of weanling albino rats of the Yale strain with an average initial weight of 50 gm. were chosen for the study. One member of each pair was fed a protein-free diet, while the other member was given an 18 per cent 'vitamin-free' casein diet for a period of 3 weeks. Each animal was kept in a separate cage and was allowed to eat and drink *ad libitum*. The basal protein-free diet was comparable in composition to that of Rechcigl, Loosli and Williams[5] with the exception of the vitamin mixture. The vitamins used in this study were supplied in the form of *GBI* B Complex Dry Mix (purchased from General Biochemicals, Inc.) supplemented with α-tocopherol and vitamin D. Vitamin A was given orally to each rat every 48 hr. in the form of vitamin A acetate at a level of 30 I.U. Following a 3-week experimental period, the animals were killed and their livers analysed for the vitamin A content by the method of Ames *et al.*[6]. As a control, vitamin A was also determined in the livers of two additional rats at the beginning of the experiment. The livers of these control animals were found to contain 14·9 and 17·1 μgm. vitamin A.

The results of the experiments are shown in Table 1. The animals which were fed a protein-free diet lost an average of 16 gm. body-weight while those fed the casein diet gained 72 gm. in a 3-week experimental period. Despite this large loss of weight, the rats kept on a protein-free ration stored just as much vitamin A in the liver as did the animals fed a ration supplemented with 18 per cent casein. In fact, the casein-fed rats stored less vitamin A than the animals kept on a protein-free diet. Thus the average liver vitamin A content of the former group was 54·7 μgm. and that of the latter 96·1 μgm. In view of the considerable difference between the liver weights of the two groups it was of interest to compare the vitamin A content when expressed per unit of weight. The casein-fed rats contained an average of 9·3 μgm. vitamin A/gm. liver whereas the rats which were kept on a regimen devoid of any protein stored 71·2 μgm./gm. liver. The lower vitamin A value in the former group can be possibly explained by greater requirement of vitamin A for the purposes of rapid growth.

Table 1. GROWTH AND LIVER VITAMIN A STORAGE OF RATS FED 18 PER CENT CASEIN DIET AND PROTEIN-FREE DIET

Pair No. and sex	Protein-free		18 per cent casein	
	Weight gain (gm./3 weeks)	Vitamin A (μgm./liver)	Weight gain (gm./3 weeks)	Vitamin A (μgm./liver)
1 ♀	−13	103·2	70	64·4
2 ♀	−13	107·0	56	54·1
3 ♂	−16	75·0	83	39·6
4 ♂	−15	91·2	71	44·0
5 ♂	−19	94·1	70	47·3
6 ♂	−20	106·3	83	35·5
Average	−16	96·1	72	54·7

These results clearly demonstrate that under the given experimental conditions the rats fed a diet lacking in protein were able to store large amounts of preformed vitamin A in their livers, suggesting that protein is not absolutely essential for this process. This finding is supported by a recent observation of Arnrich and Pederson[7] that the level of dietary protein has no effect on vitamin A storage in the liver.

Bioassay of Sheep Anterior Pituitary Glands

A HIGHLY significant seasonal variation in frequency of twin ovulations in Merino ewes was observed by Radford[1]. In order to determine whether this was correlated with seasonal variation in pituitary gonadotrophin content the surviving ewes from Radford's experiment were later killed—16 in mid-summer (January–February 1958) and 11 in mid-winter (June–July 1958). Each ewe was killed 14 days after œstrus.

From examination of the corpora lutea present in the ovaries at slaughter it was determined that seven of the 16 ewes in January–February, and eight of the 11 ewes in June–July had shed two ova at the recorded œstrus. The pituitary glands were removed, trimmed, deep frozen immediately after slaughter, and stored at −17° C. In October 1958, each gland was homogenized with 3 ml. distilled water. 1 ml. of a buffer (sodium borate, 0·05 ionic strength; sodium chloride, 0·45 ionic strength; *p*H 8·8) was then added to each homogenate. After

† Groups consisting of ewes which had shed one or two eggs at the recorded œstrus, at the two slaughter times January–February or June–July.

1½ hr. extraction they were centrifuged and the supernatants freeze-dried. All steps were carried out at 0° C. The resultant powders were dissolved, each in 1·0 ml. distilled water, and the extracts were assayed simultaneously, using the immature mouse uterine weight assay[2]. Pairs of mice were injected subcutaneously with 0·3 ml. or 0·1 ml. per mouse and killed 44 hr. later. Mouse uterine and body-weights were recorded at autopsy and the data, after log transformation, were submitted to analysis of variance using the pair totals corrected for concomitant variation due to body-weight differences (Table 1). The results for two sheep were incomplete, due to the responses at the lower level being minimal. However, the pair totals in these cases were treated as missing plots with the appropriate reduction in degrees of freedom for error.

The slopes of the log dose – log response lines were homogeneous (mean slope, $b = 34{\cdot}5 \pm 10{\cdot}8$) and the mean responses for each pituitary gland differed significantly from sheep to sheep. There were no significant differences between the mean responses of the four groups of sheep.

The following conclusions seem warranted from the results.

There were no appreciable seasonal differences in gonadotrophin content of the glands in this experiment. Indeed, the lack of any difference between ewes which had shed one or two ova at the one time of the year, and the variability between individual sheep suggest that seasonal differences would have to be large to be observed. It is not known to what extent, if any, the different periods of storage at −17° C. contributed to this result. The weights of the frozen pituitary glands or body-weights of the sheep did not contribute to the variability between sheep since the correlations between response and pituitary weight (0·06) and response and body-weight (0·11) were non-significant.

The mouse uterine weight response has been shown to give satisfactory results and should find wider application in examining individual pituitary glands for gonadotrophin content. This is important since recent work by Lamond and Claringbold[3] has shown that numerous gonadotrophins elicit similar joint action in uterine responses, thus providing a uniform basis for interpretation of pituitary–gonad studies of the type described in this communication.

There is no evidence to suggest that the yield of gonadotrophin could be much increased by a different extraction procedure. However, if this could be done it would greatly increase precision of the assays by enabling the use of a greater number of mice. A minimum of eight mice per gland would be needed to allow satisfactory potency estimates of individual glands relative to a standard and if this were achieved it would make possible comparisons between different laboratories and between different times in the same laboratory.

Response of Rice to Small Differences in Length of Day

DORE[1] has recently reported the response of a Malayan rice, an 'indica' variety of *Oryza sativa* L., to small differences in photoperiod. I have obtained similar results with West African upland cultivated rices, varieties of *Oryza sativa* L. and *Oryza glaberrima* Steud. The latter is the main indigenous rice cultivated in Northern Nigeria. Monthly sowings (May to October) of two varieties of *O. glaberrima* in Ibadan—

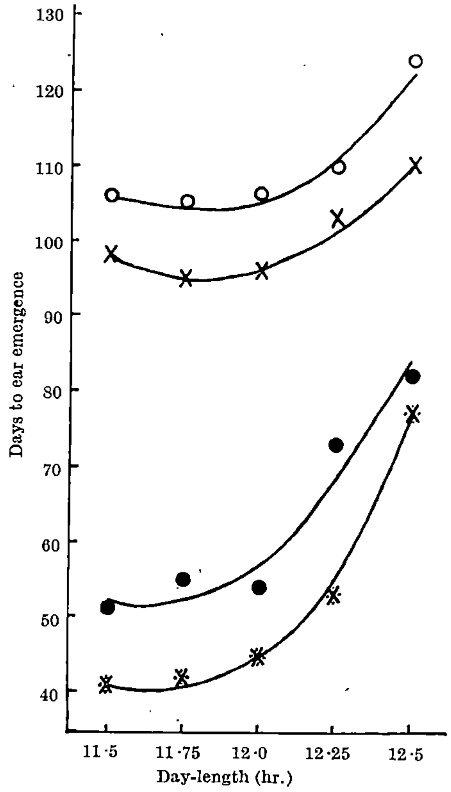

Fig. 1. Effect of small changes in photoperiod on flowering time. ○—○, *O. sativa* var. Gbengbete 223; ×—×, *O. sativa* var. Nagalawa Red Husk; ●—●, *O. glaberrima* var. Biya Gero; ✻—✻, *O. glaberrima* var. Ba Yawuri

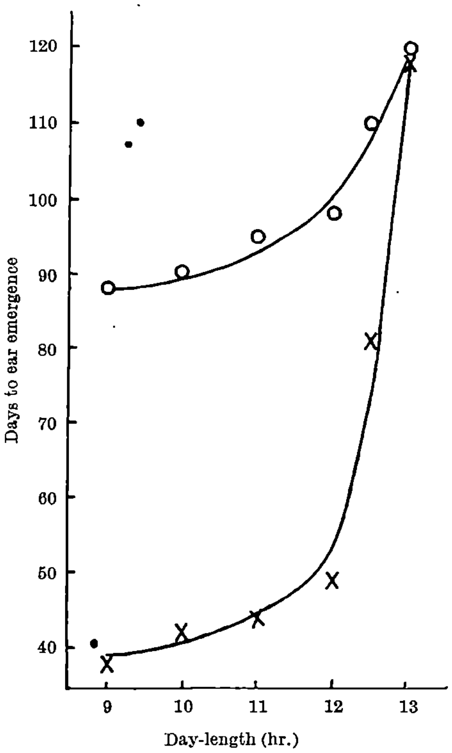

Fig. 2. Effect of photoperiod on flowering time. ○—○, *O. sativa* var. Ngalawa Red Husk ; ×—×, *O. glaberrima* var. Ba Yawuri

latitude 7° 26′ N.—showed marked variation in time to ear emergence from sowing date, the later sowings flowering earlier. The time between sunrise and sunset at Ibadan varies from 11 hr. 40 min. in December to 12 hr. 33 min. in June.

Experiments in which the plants were given constant day-lengths, controlled by time switches, of a range similar to the natural photoperiods and differing by 15 min., showed that the field behaviour could be explained by the photoperiodic response under experimental conditions. For comparison the experimental studies were extended to two varieties of *Oryza sativa* L. cultivated in Sierra Leone. Apical bud dissections carried out at regular intervals showed that the time from inflorescence initiation to emergence did not vary significantly between the day-length treatments. The day-length effect on inflorescence initiation therefore parallels that on emergence. Fig. 1 shows for four rice varieties the curvilinear relationship between the time to ear emergence and photoperiod.

The varieties of *O. glaberrima* are earlier and more sensitive than the *O. sativa* varieties, but both species show over the range of natural day-lengths a quantitative short-day response similar to that reported by Dore, although these West African rices appear to be less sensitive than the Malayan one.

From the shape of the curves shown in Fig. 1 it was expected that by decreasing the day-length below 11½ hr. the curves would rise again on the left, and it would thus be possible to define optimum photoperiods such as those reported for 'indica' varieties of *O. sativa* by Chandraratna[2]. This expectation was not fulfilled, as can be seen from Fig. 2, which gives the results of experiments with day-length treatments varying from 9 to 13 hr. There is no evidence of a lower limiting photoperiod. If there is an optimum it must be well below 9 hr., outside the range of natural day-lengths. For *O. glaberrima* var. Ba Yawuri a number of plants did not flower at the 13 hr. day-length during the period of the experiment. Thus the upper limiting photoperiod for this variety appears to be close to 13 hr.

In the experiments on the effect of small differences in day-length reported above, 15 min. differences were used because the time switches available could not measure smaller differences accurately. But it is clear from the response curves, particularly of the *O. glaberrima* varieties, that in the steep parts of the curves, day-lengths 12–12½ hr. in Fig. 1, still smaller differences in day-length would produce appreciable effects on flowering time. Previous evidence for the response of rice to small changes in day-length is provided by the work of Kuilman cited by Bünning[3]. I have reported similar responses for Nigerian plants other than rice[4]. Details of the experimental method used in the present work are as given in that paper.

I wish to thank Mr. R. Q. Craufurd of the West African Rice Research Station, Rokupr, Sierra Leone, for seeds of the varieties of *O. sativa*, and Mr. J. E. Y. Hardcastle of the Federal Rice Research Station, Badeggi, Nigeria, for seeds of the varieties of *O. glaberrima.*

Utilization of Alcohol in Germinating Pea Seedlings

Recent communications reporting a stimulation of growth in algae[1,2] and in seedlings[3] caused by added ethanol solutions have prompted us to report our findings of the ability of pea seedlings to oxidize alcohol which had accumulated under anaerobic conditions.

After soaking dried Kelvedon Wonder pea seeds in water at 20° C. for 20 hr., 404 mgm. alcohol/100 gm. fresh weight had accumulated. The peas were then placed in moving air on moist filter paper at 25° C. After 24 hr. the alcohol content had fallen to 270 mgm. alcohol/100 gm. fresh weight and 76 mgm. after 46 hr., by which time the radicles had emerged.

To check that the loss was not due to the volatility of the alcohol, a similar 100-gm. batch of peas was placed in a closed container through which an air-stream circulated. The outflowing gas-stream was bubbled through two absorption tubes containing concentrated sulphuric acid. When the alcohol content of the peas had fallen from 432 mgm./100 gm. fresh weight to 19 mgm./100 gm. fresh weight, only 22 mgm. of alcohol were recovered from the acid traps. A similar fall in alcohol content occurred when the peas were allowed to germinate under sterile conditions.

Acceleration of the loss of alcohol was caused by splitting or by complete removal of the seed coat. Thus cotyledons with 368 mgm. alcohol/100 gm. fresh weight contained 55 mgm. after 24 hr. at 25° C. The rate of carbon dioxide output and of oxygen uptake increased rapidly during the initial stages of the loss of alcohol, decreasing with time as the alcohol content was depleted. However, the stimulation in carbon dioxide output only accounted for the disappearance of about 25 per cent of the alcohol. The respiratory quotient during this period equalled 0·5.

Preliminary examination of extracts of the peas during germination have shown temporary increases in acetaldehyde content associated with the disappearance of the alcohol and also, as shown by paper chromatography, increases in acetic and citric acids.

In this tissue there is, therefore, evidence that alcohol accumulated under anaerobic conditions can be metabolized under aerobic conditions, and experiments are in progress to elucidate these problems further.

One of us (E. A. C.) is the holder of a research studentship awarded by the Department of Scientific and Industrial Research, for which grateful acknowledgment is made.

Effects of Heat and Loss of Moisture on the Dormancy of Wheat, and some Interactions with 'Mergamma *D*'

A PREVIOUS communication[1] described the action of oven treatment at 38° C. in overcoming dormancy of barley without loss of moisture. Further experiments have shown that wheat does not respond in the same manner. Oven treatment in polythene appears to have no effect, and with loss of moisture the dormancy may increase.

The following results were obtained with Cappelle Desprez Wheat, ref. *A*101, approximately three weeks after harvesting (moisture content 17·5 per cent) (Table 1).

Table 1

Treatment	Control *R*°	Refrigeration	38° C. dried		38° C. polythene	
Duration of treatment	2 days	3 days	Overnight	2 days	Overnight	2 days
Germination at six days (per cent)	46	98	34	34	51	51

Peko wheat, ref. 2019, treated with mercury/BHC seed dressing ('Mergamma *D*') behaved similarly, although the seedlings showed typical signs of stunting (Table 2).

Table 2

Dormancy treatment	Peko wheat (ref. 2019)		2019 dried	
	Non-dressed	Dressed	Non-dressed	Dressed
None	83	76	86	87
Refrigeration	86	90	89	93
Oven-polythene	—	75	—	—
Oven-dried	—	67	—	73

The dried portion had been reduced from 19 per cent to 16 per cent moisture by an 'in-sack' drier before dressing. When tested, all samples had lost a further 0·5–1·0 per cent moisture.

It is evident that the reduced germination was due not only to the laboratory drying treatment, but also to some action of the dressing. This enhancing of dormancy has been suspected for some time without definite evidence (Thomson, J. R., personal communication). When tested immediately after dressing, this sample gave the following results: control, 72 per cent; dressed normal rate, 59 per cent; dressed twice normal rate, 24 per cent. Refrigeration led to maximum germination in each case, although increased dressing gave increased stunting.

Reduction in the degree of stunting of dressed wheat can result from oven treatment with or without drying. Sometimes this is manifest as a mere ⅛-in. increase in root-length. Other samples show greater response; a root-length of ¾ in. becoming 1½ in. in the treated sample, as occurred with Peko wheat 2019.

Dressed barley responds in the same manner. One sample of Proctor tested immediately after dressing produced roots of about 1 in. long, but when oven treated (in polythene) the roots were so similar to the non-dressed control that the differences would not have noticed in routine testing. Such a strong response has not yet been noticed with any wheat samples.

These observations may be of increasing interest in view of the suggestion that seed be tested for germination under the Seeds Act after the application of dressings[2].

Effect of Pyrimidine Deoxyribonucleotides on the Regeneration of Bone-Marrow in Irradiated Mice

THE effect of several nucleotides and nucleosides on the survival and peripheral blood-count of irradiated mice was studied in our previous experiments[1]. The subject of this communication is the mitotic index in bone-marrow and deoxyribonucleic acid synthesis in the spleen in mice after irradiation and administration of pyrimidine deoxyribonucleotides.

Female mice of strain *H*, weighing 20–25 gm., were subjected to total-body irradiation at a dose of 500 r.; 0·1 mgm./25 gm. body-weight deoxycytidylic acid and 2 mgm./25 gm. thymidylic acid as the calcium salt were injected 24 hr. after irradiation. The corresponding nucleosides were injected in equimolar concentration. The mitotic index was determined before irradiation and on the fourth, seventh and tenth days thereafter; six animals of each group were used at each interval and three such experiments were performed with both cytidine and thymidine derivatives. The bone-marrow was stained by the Feulgen method and 5,000–10,000 nucleated cells were counted from the femur of each animal. The rate of deoxyribonucleic acid synthesis was determined 2 hr. after injection of phosphate-32. The deoxyribonucleic acid phosphorus from the spleen was isolated by Schmidt and Tannhauser's method.

Both deoxyribonucleotides in the given amount stimulated the regeneration of bone marrow in irradiated animals. The results were statistically significant on the fourth and seventh days after irradiation. On the tenth day and after injection of nucleosides, the differences were no longer significant. In Fig. 1 the effect of thymidine and thymidylic acid is shown, the mean value before irradiation being taken as 100 per cent. This corresponds to 11·3 mitoses/1,000 nucleated cells.

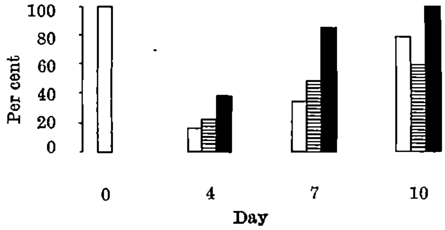

Fig. 1. The mitotic index in mice bone-marrow on the fourth, seventh and tenth day after irradiation and injection of saline (white); 2 mgm. calcium thymidylate (black); and 1·25 mgm. thymidine (shaded)

The number of chromosomal aberrations was somewhat higher in animals treated with deoxyribonucleotides than in the control group (on the fourth day 12 per cent compared with 11 per cent, on the seventh day 10 per cent and 5 per cent) but the differences were not statistically significant. In similar experiments with unirradiated mice the mitotic index was not influenced.

The changes in deoxyribonucleic acid synthesis were in the same sense as the changes in the mitotic index in bone-marrow. Results obtained on the seventh day after irradiation in mice injected with deoxycytidylic acid and deoxycytidine are given in Fig. 2.

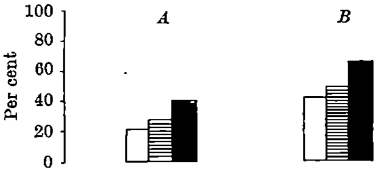

Fig. 2. The mitotic index in bone-marrow (*B*) and the rate of deoxyribonucleic acid synthesis in spleen (*A*) on the seventh day after irradiation and injection of saline (white); 0·1 mgm. deoxycytidylic acid (black); or 0·075 mgm. deoxycytidine (shaded)

The results thus agree with those arrived at in previous studies of the peripheral blood count. They show that pyrimidine deoxyribonucleotides hasten the regeneration of hæmatopoietic tissue after irradiation.

Mixed Pigments in Colour Vision

Rushton[1] has recently suggested that the 'red' mechanism of the normal eye depends upon a mixture of two light-sensitive pigments, one of which is the same as that used for the 'green' mechanism. Marriage[2] has pointed out that addition of 'green' sensitivity to the red mechanism in this way will not affect the position on the chromaticity diagram of the red fundamental stimulus, but will affect that of the green fundamental stimulus, and will move it towards or away from the red fundamental point.

It is interesting to observe, therefore, that while the red and blue fundamental points have been determined by a number of different workers to a fair degree of consistency, efforts to locate the green point have always shown considerable scatter in the red–green direction; indeed, while some locations are at the green end of the diagram[3] others are in the opposite direction in the region well beyond the red end of the diagram[4]; and, while this abrupt difference is an artefact of the diagram itself, there is none the less a very considerable scatter.

It seems possible, then, that this scatter, which has for so long confounded efforts to locate the green fundamental point, may be caused in large part by variations in the relative amounts of the two pigments present in the red mechanism of the eye, the proportions of which could depend in various ways on the viewing conditions.

BIOCHEMISTRY

Native Tobacco Mosaic Virus Protein of Molecular Weight 18,000

X-ray diffraction data on tobacco mosaic virus have been interpreted in terms of protein repeat units with a molecular weight of about 18,000 arranged in a helix[1]. Amino-acid analyses and end-group titrations[2] yield a similar minimal value but do not answer the question whether the ultimate molecular weight is 18,000 or some integral multiple of it. Thus far, the smallest native protein particles obtained by degradation of tobacco mosaic virus[3-5] have shown molecular weights of about 100,000. We have now been able to dissociate tobacco mosaic virus protein into undenatured particles with a sedimentation coefficient consistent with a molecular weight of 18,000.

Sedimentation studies were carried out in the synthetic boundary cell in a 'Spinco' ultracentrifuge at temperatures of 0–6° C. on protein prepared by treatment of tobacco mosaic virus at *p*H 10·3 and afterwards diluted to concentrations as low as 0·01 per cent with 0·05μ phosphate buffer at *p*H 7, with 0·1μ phosphate buffer at *p*H 6·5 or with 0·1μ borate buffer at *p*H 9. The centrifuge was operated at 59,780 r.p.m. and the boundary migration was followed by schlieren optics. As can be seen in Fig. 1, when the protein is diluted, the sedimentation-rate decreases from the value of about 4 Svedbergs frequently observed. The minimum value was 1·9

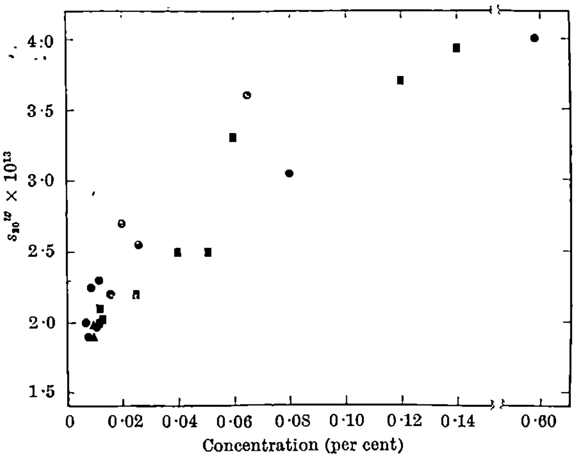

Fig. 1. Sedimentation coefficients of tobacco mosaic virus protein at various concentrations. ●, 0·10μ borate buffer, *p*H 9·0; ▲, 0·05μ phosphate buffer, *p*H 7·0; ■, 0·10μ phosphate buffer, *p*H 6·5

svedbergs. Control experiments were performed on Southern bean mosaic virus nucleoprotein diluted to the same low concentrations. Sedimentation coefficients agreed well with values extrapolated from determinations made at higher concentrations, thereby demonstrating that reliable measurements can be obtained by the method used.

If the X-ray diffraction data on the nucleoprotein of tobacco mosaic virus have been interpreted correctly, then the ultimate particle of the virus must be a truncated wedge with a maximum dimension or length of 70 A., with a thickness of 23 A. and with a maximum width of 34·8 A. It is virtually certain that the coefficient of friction lies between those of two elongated ellipsoids of revolution, both with semi-major axis of 70/2 A. and one with a semi-minor axis of 23/2 A. and the other with a semi-minor axis of 34·8/2 A. This type of reasoning, introduced by Lauffer and Szent-Györgyi[6], proved successful in interpreting the sedimentation behaviour of myosin and myosin fragments. The translational coefficient of friction, *f*, for randomly oriented elongated ellipsoids of revolution is given by the equation:

$$f = \frac{6\pi\eta b \sqrt{(1 - a^2/b^2)}}{\ln\left(\frac{1 + \sqrt{(1 - a^2/b^2)}}{a/b}\right)}$$

where η is the coefficient of viscosity, b is the semi-major axis and a is the semi-minor axis. The coefficients of friction in a medium having the viscosity of water at 20° C. for the smaller and for the larger ellipsoid are $3{\cdot}49 \times 10^{-8}$ and $4{\cdot}52 \times 10^{-8}$ C.G.S. units, respectively. By using the sedimentation formula:

$$s = \frac{M\,(1 - V\rho)}{Nf}$$

where s is the sedimentation coefficient corrected to water at 20° C., M is the molecular weight, N is Avogadro's number, V is the partial specific volume and ρ is the density of the medium, one can calculate the range of molecular weights consistent with a sedimentation coefficient of $1{\cdot}9 \times 10^{-13}$ C.G.S. units. The value of V was taken[4] to be 0·74 ml./gm. Molecular weights of 15,000 and 20,000 were obtained with the higher and with the lower friction coefficient, respectively. Since these values bracket 18,000, the sedimentation coefficient of 1·9 Svedbergs is concordant with the protein repeat unit postulated in the tobacco mosaic virus structure derived from X-ray diffraction studies. In a similar way, it can be shown that a sedimentation coefficient of 1·9 Svedbergs could not correspond to integral multiples of the 18,000 molecular weight. Comparable low molecular weights have been reported previously for the denatured protein of tobacco mosaic virus[7,8].

Several methods have been used to re-concentrate the diluted tobacco mosaic virus protein. The most successful involved dialysis against a 30 per cent aqueous solution of polyvinylpyrrolidone. Approximately ten-fold re-concentrations and recoveries of 50–70 per cent were obtained for material initially diluted in 0·05μ phosphate buffer at *p*H 7. The re-concentrated protein, adjusted to *p*H 6·5, polymerized into rods when the temperature was raised to 25° C., as described by Lauffer *et al.*[5] for the s_4 component. It was also reconstituted with tobacco mosaic virus nucleic acid into rod-like nucleoprotein particles. Polymerization can be obtained readily. Reconstitution has been completely successful in one experiment; attempts to achieve it under somewhat different conditions of *p*H and ionic strength have thus far failed. Therefore, the dissociated protein must have remained native.

The present work provides the first direct experimental evidence known to us for the existence of a native sub-unit of tobacco mosaic virus protein with a molecular weight agreeing with the value of 18,000 postulated in the interpretation of X-ray diffraction patterns.

Differences in Chromatographic Patterns of Deoxyribonucleic Acid from Various Tissues

THE constant deoxyribonucleic acid content per set of chromosomes[1,2] and the close similarity of average base composition of deoxyribonucleic acid[3] in various tissues in an animal species can be explained by assuming that the replication of all chromosomal deoxyribonucleic acid initially present in the fertilized ovum follows precisely the Watson–Crick model[4] during the ontogenesis. Recent observations of Bendich *et al.*[5], however, revealed that deoxyribonucleic acid from one animal source is heterogeneous and can be represented as a 'chromatographic profile' as fractionated on an 'Ecteola' cellulose column[6]. Such profiles are different from one tissue to another even in a single mammalian species. The most remarkable difference was found between rat kidney and rat brain. This observation is difficult to reconcile with the Watson–Crick replication model, and suggests a pronounced differentiation of deoxyribonucleic acid during ontogenesis. In repeat-

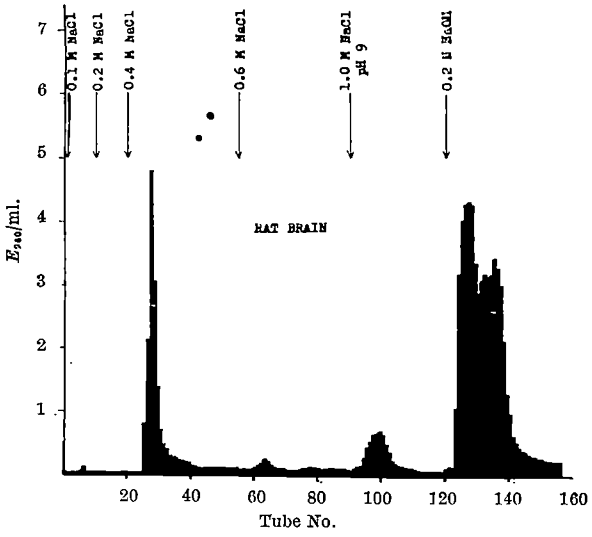

Fig. 1

ing the experiments of Bendich *et al.*, we have obtained a different result, which will be described below.

Twenty adult rats, each weighing about 200 gm., were killed by decapitation. Brain and kidney tissues were quickly removed and immersed in 0·14 *M* sodium chloride–0·01 *M* sodium citrate containing ice. Deoxyribonucleic acid was prepared in parallel from these two tissues by the method of Kay, Simmons and Dounce[7]. The procedure used in the chromatographic fractionation was essentially that described by Osawa and Sakaki[8].

Figs. 1 and 2 show the chromatographic patterns of these preparations. It is clear that no remarkable difference exists between deoxyribonucleic acid from brain and kidney with respect to chromatographic behaviour.

Similar fractionations were carried out on samples of deoxyribonucleic acid prepared from kidney, liver, appendix and testis of adult albino rabbits. In most of these experiments, except for testis, nucleohistone was first prepared according to Mirsky and Pollister[9], followed by the removal of proteins with 'Duponol' by the method of Kay *et al.*[7]. All deoxyribonucleic acids again showed similar patterns in so far as the conditions of preparation and chromatographic fractionation were kept constant. It was, however, found that the sample prepared from nucleohistone and that prepared by the original procedure of Kay *et al.*[7] gave somewhat different pictures. This suggests, as already pointed out by Bendich *et al.*[10], that the chromatographic 'profiles' are largely influenced by the methods of preparation. In any event, we could find no evidence of tissue specificity in this respect, even when the comparison was made on the deoxyribonucleic acids of rat kidney and rat brain, between which the existence of a remarkable difference of 'profiles' had been emphasized[5,11,12].

Discrepancy between our results and those of Bendich *et al.* may be due in part to the different methods of preparation. In our opinion, a reliable procedure for deoxyribonucleic acid preparation applicable to all tissues should be established before any precise chromatographic comparison is attempted.

Bromination of Nucleic Acids and their Derivatives

RECENT communications on this subject[1–3] have prompted us to report some results of observations which include an extension of work previously described by one of us[4,5].

Suzuki and Ito[1] have reported the effects of bromine on the ultra-violet absorption spectra of some purines, pyrimidines and nucleosides. There was almost complete elimination of the characteristic maxima in the absorption in the region 245–280 mμ, except for adenosine, which was practically unaffected by treatment with the strongest reagent used (1 drop of saturated bromine water to 3 ml. of 7 × 10^{-5} *M* nucleoside).

In the present investigation purines, pyrimidines, nucleosides and nucleotides were treated as follows with bromine water at slightly greater concentrations than those used by previous workers.

A solution (10 ml.) of the substance (0·1 mgm.) in either distilled water or 0·1 *N* hydrochloric acid was treated at room temperature with saturated aqueous

Table 1. Effect of Bromination on the Ultra-violet Absorptio Spectra of Purines, Pyrimidines, Nucleosides and Nucleotides

Compound	Brominated in distilled water	Brominated in 0·1*N* hydrochloric acid
Adenine	Peak at 260 mμ eliminated	Peak at 262·5 mμ unchanged
Adenosine	Peak at 260 mμ unchanged	Peak at 257 mμ unchanged
Adenosine-3′-phosphate, -5′-phosphate, -5′-triphosphate; deoxyadenosine	Peak at 260 mμ slightly reduced	Peak at 257 mμ unchanged
Guanine; guanosine; guanosine-2′(3′)-phosphate	Peaks in the region 245–255 mμ and 275 mμ eliminated	
Cytosine; cytidine; cytidine-2′(3′)-phosphate; deoxycytidine-5′-phosphate	Peak at 267 or 270 mμ eliminated; new peak at 235 mμ	Peak at 275 or 280 mμ eliminated
*Iso*cytosine	Peak at 285 mμ eliminated	Peak at 257 mμ eliminated
Thymine; thymidine; thymidine-5′-phosphate	Peak at about 267 mμ eliminated	
Uracil; uridine; uridine-2′(3′)-phosphate	Peaks at 258 or 262 mμ eliminated	
4-Aminopyrimidine	Peak at 235 mμ almost eliminated	Peak at 245 mμ eliminated

bromine water (0·25 ml.). After 10 min. the bromine was removed by 10 min. vigorous aeration and the ultra-violet absorption spectra of the solutions measured. The results (given qualitatively in Table 1) were in agreement with those reported previously[1] and, in particular, the resistance of adenosine to the action of dilute aqueous bromine was confirmed. Deoxyadenosine and the phosphates of adenosine reacted very slightly with bromine.

The resistance of derivatives of adenine suggested that bromination might be used as a method for the specific degradation of nucleic acids. For this purpose deoxyribonucleic acid (DNA) was treated with bromine as follows:

The deoxyribonucleic acid of calf thymus, isolated by Marko and Butler's method[6] (25 mgm.), was dissolved in 25 ml. of acetate buffer (*p*H 6, ionic strength 0·1) and mixed with 12 ml. chloroform. A solution of bromine in chloroform (1·25 ml.; 10 mgm. bromine/ml.) was added and the solution shaken at 20° C. for 30 min. The mixture was then centrifuged, when a gel layer (not produced by the original deoxyribonucleic acid) was formed at the chloroform–water interface. This was due to the formation of an insoluble gel during the bromination of the deoxyribonucleic acid.

The aqueous and gel layers were combined and treated with ethanol (3 vol.). The precipitate so produced was only partly soluble in water so a suspension of the material was exhaustively dialysed and then freeze-dried to give a yellow solid, designated $BDNA_1$ (22 mgm.).

The deoxyribonucleic acid was also brominated at 2° instead of at 20° C. to give $BDNA_2$ (25 mgm.), and at 20° C., without including chloroform in the reaction mixture and using bromine dissolved in acetate buffer, to give $BDNA_3$ (25 mgm.). These samples were analysed by Dr. D. S. Letham, using formic acid hydrolysis and paper chromatographic separation and estimation of the purines and pyrimidines[7]. The results are shown in Table 2. 5-Methylcytosine was not estimated.

Table 2. Base Composition of Brominated Calf-Thymus Deoxyribonucleic Acid

(Moles of base per 4 atoms of phosphorus)

	Adenine	Thymine	Guanine	Cytosine
DNA	1·10	1·12	0·84	0·86
$BDNA_1$	1·00	0·25	0·12	0·18*
$BDNA_2$	0·95	0·72	0·40	0·49*
$BDNA_3$	0·91	0·60	0·22	0·35*

* Estimated as cytosine, but was probably a mixture.

The identities of the adenine, guanine and thymine in the samples of brominated deoxyribonucleic acid were established by comparison with the R_F values and ultra-violet absorption spectra of the corresponding bases present in the original deoxyribonucleic acid. The cytosine spot on chromatograms of hydrolyses of the brominated deoxyribonucleic acid, although corresponding in R_F value with authentic cytosine, had, in 0·1 *N* hydrochloric acid, an ultra-violet absorption spectrum with a broad flat peak with a poorly defined maximum at 280 mμ. This component was not investigated further, but it was probably a mixture of cytosine with a brominated product ($\varepsilon_{\text{max.}}$ of 5-bromocytidine is at 289 mμ at *p*H 7, ref. 8).

A satisfactory ultra-violet absorption spectrum of the brominated deoxyribonucleic acid was not readily obtainable due to the partly insoluble nature of the material. When $BDNA_1$ was dissolved in 0·1 *N* sodium hydroxide, however, and allowed to stand for 10 min. at 37° C. a drop in the absorption at 260 mμ of 53 per cent as compared with the original deoxyribonucleic acid was obtained. No further reduction in optical absorption occurred on standing at 37° C. for a further 48 hr. The alkali treatment also caused degradation of the molecule as shown by the fact that treatment with 0·1 *N* sodium hydroxide at 37° C. for 15 hr. caused 50 per cent of the material absorbing light at 260 mμ to become dialysable.

Since thymine derivatives were as readily attacked by bromine as were cytosine and guanine derivatives, the relative resistance of the thymine in the deoxyribonucleic acid was remarkable. It appeared possible that the hydrogen bonding of the thymine in deoxyribonucleic acid to the bromine-resistant adenine may have afforded protection to the thymine residues. Another explanation was that some of the thymine may have been regenerated by the acid hydrolysis used to determine the base composition of the brominated deoxyribonucleic acid. The second explanation was supported by the following results.

Derivatives of thymine, cytosine and uracil were treated in aqueous solution with bromine water as previously described. The solutions were next concentrated *in vacuo* and then treated with either 40 per cent formic acid or with 7 *N* hydrochloric acid at 100° C. for 30 min. The solutions were then freed from acid and the ultra-violet absorption spectra determined.

The results (Table 3), some of which are similar to those reported by Cohn[3], suggest that brominated thymine is converted into thymine on acid hydrolysis, whereas brominated cytosine and brominated uracil are not converted into the original bases, but into other ultra-violet absorbing products. The fact that all the thymine and large amounts of a cytosine derivative were not recovered from the hydrolysates of the brominated deoxyribonucleic acid may have been due to the more drastic hydrolysis conditions (98 per cent formic acid at 175° C.) used for the base analysis than for the hydrolysis of the brominated pyrimidines.

Although the adenine in deoxyribonucleic acid was relatively resistant to bromination, it was obvious that considerable destruction of the adenine would occur if bromination of the other bases were carried to completion. It appeared, therefore, that bromine was not so selective as was potassium permanganate

Table 3. ACTION OF ACID ON THE ULTRA-VIOLET ABSORPTION SPECTRA OF BROMINATED PYRIMIDINES

Brominated compound	Treatment at 100° C. for 30 min. with : 40 per cent formic acid	7 *N* hydrochloric acid
Thymine	Spectrum identical with that of the original thymine	
Thymidine-5′-phosphate	As for thymine*	—
Uracil	Peak at 275 mμ, 65 per cent of the height of that of uracil at 260 mμ	Peak at 275 mμ, 90 per cent of the height of that of uracil at 260 mμ
Cytosine	Peak at 277 mμ. Same absorption as that of cytosine at 267 mμ	—

* The solution of thymidine-5′-phosphate after bromination and treatment with formic acid was again treated with bromine water. The peak at 267 mμ was again eliminated.

at 37° C., a reagent, which, as has already been reported[9], oxidized almost completely the guanine, cytosine and thymine in deoxyribonucleic acid, but left 95 per cent of the adenine intact. The latter reagent is, therefore, superior to bromine for the determination of the distribution of adenine in deoxyribonucleic acid.

We wish to thank Prof. M. Stacey for his interest, Mr. C. G. James for technical assistance and the British Empire Cancer Campaign (Birmingham Branch) for financial support.

Androgens in the Bovine Testis and Spermatic Vein Blood

BULL testis is the organ from which testosterone was first isolated nearly twenty-five years ago[1]. Information is still scarce, however, on the hormone content of this gland at various stages of the animal's development, nor is it known at what age androgenic steroids are first secreted by the gonads in appreciable amounts. Hooker[2] was able to demonstrate the presence of unidentified androgenic material in the testes of prepuberal calves by bioassay. Recent evidence, derived from the chemical analysis of seminal plasma and accessory secretions, indicates that already at the early age of 4–5 months a source of androgens must be present in bull calves, sufficient to induce specific secretory activity in the male accessory glands[3]. The present study was intended to supplement these observations by direct determination of androgenic steroids in the testicular tissue and the spermatic vein blood of the bull.

Material from 25 animals of both dairy and beef breeds, varying in age from 39 days to 17 years, was examined. The 'neutral ketonic fraction' separated from testicular lipid extracts was partially purified by a countercurrent distribution and resolved by paper chromatography in systems developed by Bush[4]. Compounds exhibiting the ultra-violet absorption curve of an α-unsaturated 3-oxosteroid were determined by their absorption at 240 mμ. Additional evidence on the identity of the extracted steroids was obtained by the examination of their absorption spectra in concentrated sulphuric acid and the study of the products formed by acetylation and oxidation or by treatment with Zimmermann's alkaline *m*-dinitrobenzene reagent; finally, purified material was submitted to infra-red spectral analysis. Blood samples were obtained from the spermatic vein of a number of animals and analysed by similar methods. The results were briefly as follows.

Both testosterone (17β-hydroxyandrost-4-en-3-one) and androstenedione (androst-4-en-3 : 17-dione) were identified as constituents of the bull testis at all stages of sexual development, and could be detected at an age as early as 39 days. Per unit weight of tissue, the combined content of the two steroids was not very different in the testes of very young calves (0·4–9 μgm./gm.) and those of fully grown bulls (1–6 μgm./gm.). However, whereas in the mature bull the major testicular androgen was testosterone, in the young calves the predominant steroid was identified as androstenedione. The ratio testosterone/androstenedione was greater than 15 in each of eight adult bulls, but never higher than 0·7 in the eleven calves less than 4 months old.

This pattern was clearly reflected in the steroid composition of the spermatic vein blood. Androstenedione predominated in the blood of 3 months old calves, testosterone in that of adult bulls, while an intermediate ratio of testosterone to androstenedione (approximately 3 : 1) obtained in 4–7 months old calves. Treatment of young male calves with human chorionic gonadotrophin increased both the rate of secretion of androstenedione and its concentration relative to testosterone in the spermatic vein blood. Thus, for example, 0·12 mgm. androstenedione and 0·03 mgm. testosterone were secreted per hr. in the untreated member of a pair of 3 months old monozygous twin calves, while in the other member of this pair, which had received gonadotrophin injections (2,000 I.U./48 hr.) for 7 weeks, the secretion-rate increased to 1·08 mgm. androstenedione and 0·04 mgm. testosterone/hr. By contrast, adult bulls responded to treatment with the trophic hormone with a marked and immediate increase in testosterone secretion. Small amounts of two further steroids were detected by paper chromatography in the spermatic vein blood of gonadotrophin-stimulated calves. Their R_F-values, absorption maxima and behaviour towards acetylating and oxidizing agents and the Zimmermann reagent were those of progesterone and 17α-hydroxyprogesterone (17α-hydroxypregn-4-en-3 : 20-dione).

An additional component was present in a number of extracts of spermatic vein blood collected from bull calves and was shown to be *epi*testosterone (17-α-hydroxyandrost-4-en-3-one). There was reason to believe, however, that this unusual steroid was not secreted as such by the testis, but was formed by the subsequent action of the blood on a substrate of testicular origin. When androstenedione was added to sterile blood (ox or sheep) and the mixture incubated aerobically at 35° C., there occurred a rapid formation of *epi*testosterone, together with smaller amounts of testosterone. This phenomenon was not observed in plasma separated from corpuscles, nor in washed blood corpuscles resuspended in saline.

The present investigation has demonstrated by means of direct chemical determination of steroids that androgenic substances are secreted by the bovine testis into the blood stream already at a very early age. *In vitro* studies by Slaunwhite and Samuels[5] have indicated the following sequence of biosynthetic reactions in rat testicular tissue: Progesterone → 17α-hydroxyprogesterone → androstenedione → testosterone. Our results suggest that the conversion of androstenedione to testosterone may be a rate-limiting reaction in the elaboration of testosterone by the immature bovine testis. A transition to a secretion in which testosterone is predominant would seem to precede the appearance of pubertal changes in this species.

This study is now being extended to other species of farm animals, and in the adult ram, for example, both testosterone and androstenedione were shown to be present in the spermatic vein blood in proportions similar to those found in the bull.

This work has been carried out during the tenure of a scholarship awarded by the Commonwealth Scientific and Industrial Research Organization, while on leave from the Sheep Biology Laboratory, Prospect, N.S.W. I am grateful to Dr. T. Mann for his counsel and continued stimulating interest, to Dr. R. V. Short for advice, and to Mr. L. E. A. Rowson for his generous help in collecting animal material.

Acid Mucopolysaccharides of Normal Urine

The occurrence of at least one acid mucopolysaccharide in normal urine has repeatedly been reported[1-3]. It was found by various authors[1-3] to behave chromatographically and electrophoretically like chondroitin sulphate *A*. Separation and staining, however, were unsatisfactory.

We recently described[4] a convenient and highly specific staining method for acid mucopolysaccharide in which use was made of a 1 per cent solution of alcian blue (Gurr or Harleco) in a 9 : 1 mixture of acetic acid and water (5 min.), followed by alternate washings with acetic acid and tap water. The intensely blue acid mucopolysaccharide spots stand out on a pure white background, and as little as 0·5 μgm. of heparin or 2·0 μgm. of chondroitin sulphate *A* can be detected. Scanning allows quantitative estimations, since the uptake of dye appears to be proportional to the acid mucopolysaccharide concentration over a wide range. A correction factor is nevertheless required to allow for different specific dye uptakes by different acid mucopolysaccharides.

By using an ultrafiltration and dialysis method, to be described elsewhere, it was possible to concentrate normal urines up to 3,000 times without any denaturation of their colloids. Electrophoresis on Whatman No. 1 filter paper in a veronal–acetate buffer of *p*H 8·6 and ionic strength 0·1, using 3 V./cm. for 12 hr., resulted in very sharp separation of three different acid mucopolysaccharides, which migrated ahead of the albumin peak. The fastest and most abundant peak migrated about twice as fast as albumin, and at exactly the same speed as commercial chondroitin sulphate *A*. This is presumably the substance described by other authors[1-3]. The second peak, which was usually though not always smaller than the first, had a mobility of about 1·5 times greater than albumin. The third and smallest peak was about 1·1 times faster than albumin. None of these substances could be stained by protein dyes.

Fig. 1. Urinary acid mucopolysaccharides separated by electrophoresis at *p*H 8·6 and stained with alcian blue. The albumin (unstained) is indicated by arrows

All three appeared to have some anticoagulant activity of the heparin type, which casts considerable doubt on their identification as chondroitin sulphates *A* or *C*, which are known to be devoid of anticoagulant properties. On the other hand, commercial alpha-heparin samples ('Liquaemin', Roche) was found to migrate distinctly faster than the fastest urinary acid mucopolysaccharide peak.

The identification of these three substances must await further investigation, which is now in progress in our laboratory.

Persistence of Cholesterol-4-^{14}C in the Central Nervous System

Recent work from this laboratory[1,2] has shown that once cholesterol-4-^{14}C is incorporated into the central nervous system of developing rabbits and chickens it remains with little change for more than a year. It seems likely that this radioactive cholesterol is incorporated into the myelin sheath, but there remains the possibility that once in the central nervous system the cholesterol undergoes internal turnover, being broken down and resynthesized *in situ*. This communication presents evidence to show that the radioactive carbon atom, even after 18 months, remains in its original position in the cholesterol molecule. In these experiments cholesterol extracted from the central nervous system with chloroform–methanol (2 : 1) was isolated by fractionation on an alumina column. The cholesterol was converted to cholestenone by an Oppenauer oxidation[3]. Next the radioactive cholestenone was ozonized

Table 1. Localization of Radioactivity in the Cholesterol Ring

Time after injection (days)	Dose given (μc.)	Specific activity (c.p.m./mgm. of cholesterol or its equivalent)			
		Crude extract	Cholesterol	Cholestenone	Keto-acid (I)
375 (rabbit)	5	45	47	35	1·8
502 (chicken)	3	22·9	23·4	14	0·96

A crude lipid extract in alcohol–ether (3 : 2) or chloroform–methanol (2 : 1) was obtained from the central nervous system of animals injected with cholesterol-4-^{14}C soon after birth. Pure cholesterol was obtained by recrystallization of cholesterol separated from the crude extract by column chromatography. Cholestenone and the keto-acid were prepared as described below.

and then oxidized with hydrogen peroxide by the method of Turner[4]. The keto-acid (I) obtained as a result of this elimination of a carbon atom at position 4 was purified and recrystallized. The melting point was in agreement with that reported in the literature[4,5]. Comparison of the radioactivity of the cholesterol with the radioactivity of the keto-acid (Table 1) shows that almost all the activity disappears on elimination of the 4-C atom. Furthermore, it was found that all the radioactivity in the original crude extract of the central nervous system was due to its content of radioactive cholesterol (Table 1). This latter result also suggests that the cholesterol molecule remains intact in the central nervous system for more than a year, for if the cholesterol-4-^{14}C had been degraded it would be anticipated that other radioactive lipids would be synthesized from the resultant fragments. These two groups of experiments, therefore, support the view that the cholesterol that persists in the central nervous system remains metabolically inert for more than a year.

A Simplified Physico-chemical Method for Determination of Human Urinary Œstrogens

The methods for estimating urinary œstrogens are open to criticism and are not easily applied as a routine in the laboratory because of their complexity. Our chief aim in the present investigation is to develop a reliable, practical and simplified method for studying the excretion of urinary œstrogens by patients with cancer of the breast.

100 ml. urine of 24-hr. sample was adjusted to *p*H 5 with concentrated sulphuric acid. 10 per cent by volume of acetate buffer was added, followed by 300 Fishman units of β-glucuronidase/ml. urine. This was incubated at 37° C. for five days[1]. After completion of hydrolysis, the urine was extracted four times with 100 ml. peroxide-free ethyl ether. The ether extract was washed with (*a*) saturated sodium carbonate solution, *p*H 10·5, (*b*) 2 *N* sodium hydroxide solution which was neutralized to *p*H 10 with 8 per cent sodium bicarbonate solution and shaken again with the ether extracts, (*c*) 8 per cent solution of sodium bicarbonate, (*d*) water[2]. The ether extract was evaporated to dryness and the residue dissolved in about 80 ml. toluene; this was extracted four times with 0·25 volume *N* sodium hydroxide and washed twice with 0·05 volume water. Neutral steroids remain in toluene layer. Alkaline extracts and washings were acidified to *p*H 9 with sulphuric acid (6 *N*) and extracted four times with 0·25 volume ether. This was evaporated and the residue was transferred to small storage bottles with methyl alcohol and evaporated to dryness at 60° C. Counter-current distribution in 50 per cent methanol, 50 per cent water (upper layer)/carbon tetrachloride (lower layer)[3] was then carried out for 24 transfers. Œstrogen extract was dissolved in 0·2 ml. ethanol and heated in a water-bath with 1 ml. 90 per cent sulphuric acid at 80° C. for 10 min. This was diluted with 4 ml. 65 per cent sulphuric acid and cooled in crushed ice for 30 min. Fluorescence was measured in a Farrand photofluorometer model *A* using Corning glass No. 3389 and No. 5113 as the lamp filter (436 mμ) with Nos. 3387 and 4308 and a 483 mμ interference filter as the photocell filter[4–6].

The specificity, precision and accuracy of the newly developed technique are shown in Table 1. These results were obtained by running a series of recovery experiments for the three major naturally occurring œstrogens.

Table 1. Recovery of Œstrone, Œstradiol-17β and Œstriol added to 100 ml. of Normal Male Urine before Hydrolysis

Œstrogen used	Amount added (μgm.)	Percentage recovery	Partition coefficient*
Œstrone	100 50	85 82	3·4
Œstradiol-17β	100 50	91 87	2·1
Œstriol	100 50	93 94	15·3

* Between 50 per cent methanol and carbon tetrachloride.

Effect of Drugs upon Components of Bacterial Cytoplasm

ULTRACENTRIFUGAL analysis has shown that one of the main ribonucleoprotein components of bacterial cytoplasm is sensitive to alterations in the concentrations of certain salts present in the growth medium, or in the medium in which cells are suspended before they are disrupted[1-3]. This component sediments at about 40S. (uncorrected) and its breakdown within whole cells is favoured by lowering the concentration of magnesium ions or raising that of inorganic phosphate; ribonucleoprotein particles sedimenting at about 29 and 20S. are relatively insensitive to these extracellular changes in concentration.

It does not appear that the 40S. component plays any part in the metabolism of the cell which other ribonucleoprotein units of smaller molecular weight cannot share. For example, when bacteria were depleted of this component their ability to synthesize β-galactosidase was not impaired[4]. A connexion between bacterial cell-division and stability of the 40S. component is suggested by the requirement of both processes for magnesium ions. Accordingly, we examined cultures grown in the presence of 5 I.U. penicillin/ml., which stopped cell-division but allowed synthesis of cellular material to proceed, so that the whole culture eventually consisted of filamentous cells several times their normal length. However, no change was observed when schlieren diagrams were compared; the amount of 40S. component present in extracts from filamentous cells was the same as that from normal cells.

These results stand in contrast to those obtained for 'Chloromycetin' (chloramphenicol). *Escherichia coli* was grown in the medium containing peptone, glucose and inorganic phosphate as previously described[2] except that the concentration of magnesium sulphate was raised to 6·5 m*M* to avoid breakdown of the 40S. component at high cell populations[4]. During an incubation period of 150 min. five samples were removed at intervals from a control culture and, after centrifuging, the cells were disintegrated in bacterial presses[5], and five soluble cell-free extracts were obtained. The experiment was repeated using *E. coli* cells from the same overnight grown culture for inoculation but with addition of 5 μgm. of 'Chloromycetin'/ml. of growth medium; this caused a lag in both growth and cell-division, and no filamentous bacteria were observed. Ultracentrifugal analysis showed that this treatment with 'Chloromycetin' caused marked alterations in schlieren diagrams of extracts. Incubation with the drug for 30 min. resulted in a considerable increase in area of a peak sedimenting at 18S. and the appearance of a new peak at 14S.; both increased further during the lag period. In Fig. 1, schlieren diagrams for extracts from cells incubated for 30 and 150 min. with 'Chloromycetin' are contrasted with one of those obtained in the absence of the drug. Previously[2], prominent components have been designated 40, 29 and 20S. for ease of reference, although these values are subject to variations, particularly in the crude extracts studied; in the present series the measured values are respectively about 35, 22 and 18S. The additional material responsible for enlargement of the peaks at 18 and 14S. is probably the 'unstable ribonucleic acid' sedimenting as nucleoprotein, which other workers have shown to be synthesized by bacteria in the presence of 'Chloromycetin'[6-8]. A small peak sedimenting a little faster than 22S. is also seen in diagram (*b*); this was not present in diagrams for the control or in those taken later in the lag phase for cells treated with 'Chloromycetin'.

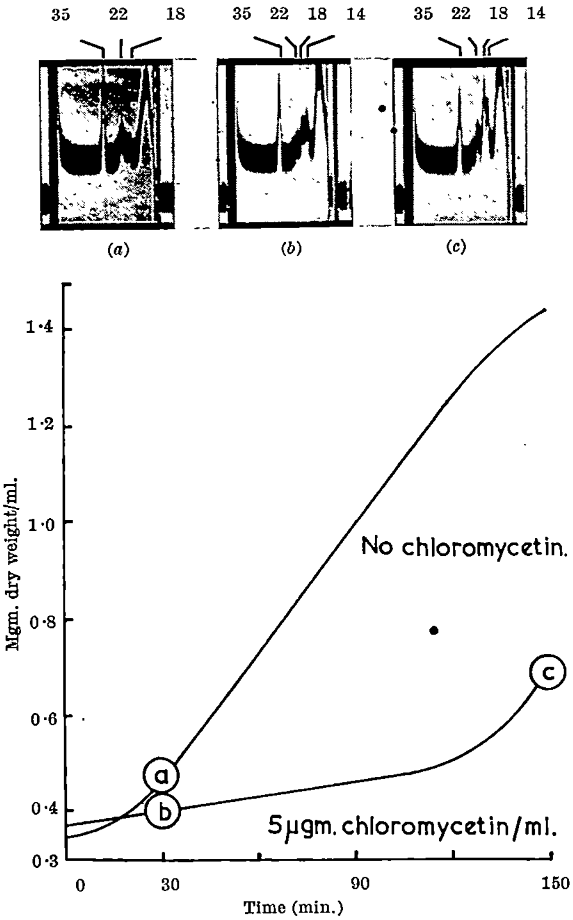

Fig. 1. Schlieren diagrams of extracts from cells (*a*) untreated, and (*b*) and (*c*) treated, with 'Chloromycetin'. Cell-free extracts were prepared in 0·06 *M* phosphate buffer at times indicated on the growth curves and were each diluted to 10 mgm. protein/ml. Photographed of the same schlieren angle (41°) at 16 min. after reaching speed of 187,000*g*. The numbers above the photographs give the uncorrected sedimentation coefficients of boundaries in Svedberg units

A second effect of 'Chloromycetin' is that produced on the '29S. component', which in Fig. 1 has a measured coefficient of 22S. As the 18 and 14S. peaks enlarged in the early part of the lag period due to the drug, so the 22S. peak diminished; and when cell-division began at 120–150 min., the 22S. peak increased rapidly in area, as can be seen by comparing diagrams (*b*) and (*c*). The area of the 35S. peak changed little during these experiments. An increase in the '29S. component' at the onset of logarithmic growth is normally observed[2]; further, this component remains when '40S.' breaks down due to changes in ion concentrations which do not impair cellular metabolism. If ribonucleoprotein particles of a critical size have a specific role in, say, synthesis of bacterial protein, then the '29S. component' appears from the present work more likely to be involved than larger units. Attempts to assign particular functions in the living cell to components of preparations made from them must always take account of the possibility that particles may have arisen simply by mechanical disintegration of larger structures. Smaller units do not always arise from such processes, however ; thus, the ribonucleoprotein components of bacterial cytoplasm tend to aggregate or associate in the presence of magnesium ions ; and unless the concentrations of these and other ions in extracts approximate to those in the living cell, the larger particles may have no greater metabolic significance than the smaller ones.

Pardee, Paigen and Prestidge[8] also found that the '29S. component' disappeared from extracts of cells which had been incubated with 'Chloromycetin' but they found no additions to the schlieren diagrams at 18 and 14S. such as we have described. However, until we have completed work on the factors affecting stability of this additional material, it must not be concluded that our results are opposed to those of Pardee *et al.* Thus we have studied cultures containing the rather high concentration of 6·5 mM magnesium sulphate which favours ribonucleoprotein association ; and it has been observed that degradation of ribonucleic acid formed during 'Chloromycetin' treatment is rapid when cells are suspended in phosphate buffer[6], conditions which also favour breakdown of the ribonucleoprotein particle sedimenting at 40S.

We are grateful to the Medical Research Council for financial support of this work. We also wish to acknowledge a gift of pure 'Chloromycetin' from Parke, Davis and Co., Ltd.

Effect of Salicylate on Muscle Phosphorylase

During the course of an investigation of the effects of salicylate on glucose metabolism it was observed that incubation of the isolated rat diaphragm in a Krebs–Ringer bicarbonate medium containing salicylate caused a loss of glycogen from the muscle. Such an observation had been made previously by Smith and Jeffrey[1], who employed a phosphate medium with higher levels of salicylate. Under the conditions of our experiments, however, the loss of glycogen from the diaphragm occurred mainly within the first 30 min. of incubation and thereafter occurred at a much slower rate despite the fact that muscle glycogen was still present in abundant amounts (a paper describing this and other effects of salicylate on glucose metabolism is in preparation). In an attempt to explain the alteration in rate of glycogenolysis occurring after 30 min., assays were carried out of active (*a* form) and total (*a* + *b* form) phosphorylase present in the muscle.

Fed male Sprague–Dawley rats (150–175 gm.) were killed by stunning and decapitation. 3–4 isolated hemidiaphragms were placed in a 25-ml. flask with 5 ml. of Krebs–Ringer bicarbonate medium *p*H 7·4 containing 100 mgm. glucose and 30 mgm. salicylate/100 ml. (this is a concentration of salicylate which when present in human blood is in the nearly toxic range). As a control, the paired hemidiaphragms were placed in medium without salicylate. After being gassed with 95 per cent oxygen, 5 per cent carbon dioxide for 30 sec., the flasks were stoppered and incubated for varying periods of time in a Dubnoff shaker at 37° C. At the end of the incubation a 10 per cent homogenate of the diaphragms was made in the cold with a Potter–Elvejhem homogenizer, using 0·01 M disodium versenate in 0·01 M phosphate buffer *p*H 7·4 as the homogenizing fluid. The homogenate was centrifuged to precipitate cell debris, and the supernatant fluid was diluted 1 : 8 with cysteine-glycerophosphate buffer *p*H 6·0.

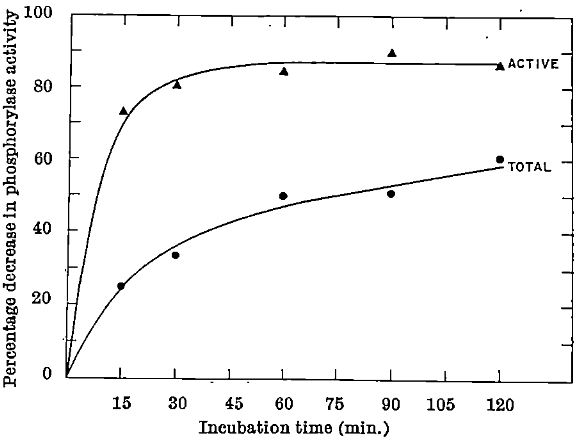

Fig. 1. Effect of incubation with salicylate on muscle phosphorylase in rat diaphragm

The phosphorylase activity of the supernatant fluid was assayed by Cori, Illingworth and Keller's method[2] and expressed as μM inorganic phosphorus[3]/mgm. of protein[4] in 20 min. Concomitant determination of glycogen[5] revealed that glycogen was synthesized in stoichiometric amounts to inorganic phosphorus liberated. When phosphorylase activity was measured by synthesis of glycogen, the findings with salicylate paralleled those obtained by measuring liberation of inorganic phosphorus. Phosphoglucomutase activity was minimal in both control and salicylate-treated preparations.

The results are shown in Fig. 1, each point representing an average of two experiments. At the end of a 15-min. incubation of the diaphragm with salicylate a 70 per cent decrease in active phosphorylase (*a* form) had occurred, eventually reaching about an 87 per cent decrease in activity. Total phosphorylase (*a* + *b* forms) showed a decrease in activity but at a much slower rate. In representative experiments shown on Table 1 the quantity of active phosphorylase in the controls ranged from 34 to 50 per cent of the total amount of enzyme present. This was reduced to 10 per cent by incubation with salicylate for 1 hr.

Since salicylate has been known to uncouple oxidative phosphorylation[6], experiments were performed with dinitrophenol, another uncoupling agent. Table 1 demonstrates that dinitrophenol produces a similar effect on muscle phosphorylase. On the other hand, parahydroxybenzoate, an isomer of salicylate, caused no decrease in the enzyme activity. Studies carried out on crystalline rabbit muscle phosphorylase

showed that salicylate in the concentration used in the diaphragm experiments produced no decrease in enzymatic activity of the crystalline material (obtained from Sigma Chemical Co., St. Louis, Mo., 2,000 U./mgm. all in active form).

In one group of experiments epinephrine hydrochloric acid (10 γ/ml.) was added to the media after the diaphragm had been incubated with salicylate for 30 min. During subsequent incubation for an additional 60 min., epinephrine increased the active phosphorylase by more than 100 per cent of the low value found in diaphragms incubated with salicylate a total of 90 min. Epinephrine had little or no effect on the level of total phosphorylase.

Since salicylate does not affect the activity of the crystalline enzyme, the decrease in phosphorylase activity in the diaphragm resulting from salicylate treatment is probably a secondary effect on one or more factors necessary for maintenance of the *a* and *b* forms of phosphorylase in the muscle. The initial and most profound effect is a decrease in active phosphorylase which could result either from a stimulation of the *PR* enzyme[7] converting the *a* to the *b* form, or from an inhibition of the activating enzyme[8] which converts *b* to *a* and which is dependent on adenosine triphosphate. The slower decrease in total phosphorylase suggests that the *b* form normally activated by adenosine-5′-phosphate is converted to a form no longer activated by the nucleotide. The effects of salicylate on phosphorylase would adequately explain the observed effects of this compound on the rates of glycogenolysis in the diaphragm.

We wish to express our thanks to Dr. Marshall Nirenberg for his helpful suggestions during the course of this work.

CHEMISTRY

5-Co-ordination of Divalent Copper

CONSIDERABLE attention has recently been given to the co-ordination of additional ligands along the axis normal to the molecular plane of planar 4-co-ordinated complexes. Ballhausen and Liehr, for example, explain the blue and yellow isomers of Lifschitz's nickel stilbene-diamine salts in terms of co-ordination of the associated anions in this way[1]; Harris, Nyholm and Stevenson have shown by X-ray analysis the analogous attachment of iodide ions in *bis*-(*o*-phenylene-*bis*-dimethylarsine)palladous iodide[2] and Sacconi, Lombardo and Paoletti have determined stability constants for the adducts of heterocyclic bases with the planar inner-complex nickel diacetyl-*bis*-(benzoylhydrazone) in benzene solution[3].

The resistance of planar complexes of divalent nickel, palladium and platinum to further co-ordination derives from the effect of the ligand field in so raising the energy of the $d_{x^2-y^2}$ orbital, which points directly at the ligands, that it remains unoccupied; the consequent pairing of electrons in the d_{z^2} orbital produces regions of high electron density normal to the molecular plane, so resisting the approach of further ligands[4]. A similar situation arises in planar cupric complexes (the $d_{x^2-y^2}$ orbital being then singly occupied), and the elongated octahedral co-ordination of this ion in crystalline salts has been known for many years[5]; but apart from this, comparatively little attention has been given to co-ordination of further groups normal to the molecular plane of cupric complexes, though the solubilities of cupric α-amino-acid chelates suggest that solution may occur by co-ordination of water in this way[6].

It thus seems of interest to report the formation in non-polar solvents of 5-co-ordinated complexes by attachment of heterocyclic bases to the planar molecules of cupric acetylacetonate and cupric ethylacetoacetate.

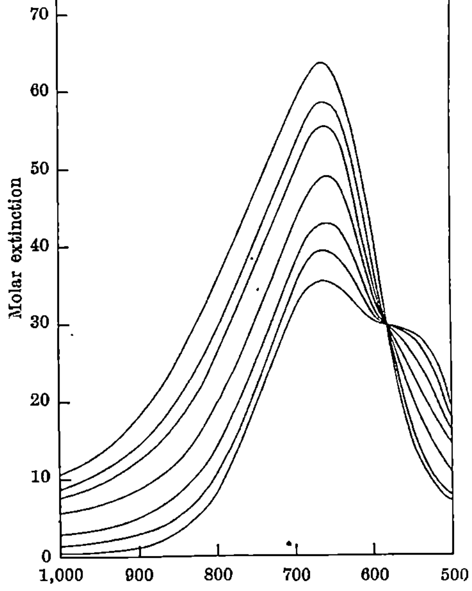

Fig. 1. Absorption spectrum of cupric acetylacetonate in chloroform with increasing concentrations of pyridine

The absorption of cupric acetylacetonate in chloroform solution is considerably modified on addition of pyridine, most noticeably by a progressive increase in extinction of the peak at 660 mμ with increasing concentration of the base. The successive absorption curves have a sharply defined isosbestic point (Fig. 1), indicating a two-phase equilibrium. The equilibrium constant, calculated from the molecular extinctions, is of the form :

$$k = \frac{[\mathrm{Cu(acac)_2.pyridine}]}{[\mathrm{Cu(acac)_2}] \times [\mathrm{pyridine}]}$$

showing that only one molecule of pyridine is co-ordinated. Though formation of the 5-co-ordinated complex is incomplete, even with a two hundred-fold excess of pyridine, the equilibrium constants are so consistent over the whole range that any alternative form of the equilibrium constant, such as that required for 6-co-ordination, can be excluded. Thus, at 20° C. with 5×10^{-3} *M* cupric acetylacetonate the results in Table 1 were obtained. Similar results were obtained with piperidine ($k = 3 \cdot 3$; extrapolated extinction of complex = 86·5). It is significant that the extrapolated absorption curves of the pyridine and piperidine complexes are, within the limits of error, identical with those observed by Belford, Calvin and Belford[7] using pure pyridine or piperidine as solvents, so that any possibility of the completion of 6-co-ordination by the solvent may be discounted. This possibility would not arise in paraffin solvents, but the solubility of cupric acetylacetonate in these is too low to allow their use ; cupric ethylacetoacetate, however, is much more soluble in paraffins, and parallel results have been obtained for its reaction in *cyclo*hexane solution at a concentration of 10^{-3} *M* with piperidine ($k = 640$; extrapolated extinction = 83), pyridine ($k = 54$; extrapolated extinction = 76), γ-picoline ($k = 36$; extrapolated extinction = 77) and α-picoline ($k = 4 \cdot 9$; extrapolated extinction = 76).

Table 1

Pyridine (*M*/l.)	0	0·045	0·105	0·195	0·400	0·600	1·00	∞
ε (660 mμ)	35·6	39·4	43·0	47·8	55·5	58·5	63·8	75·6*
Cu 5-co-ordinated (per cent)	0	9·5	18·5	30·5	49·5	57·0	70·5	100
k (mean = 2·3)	—	2·33	2·15	2·25	2·45	2·22	2·39	—

* Extrapolated.

The general trend of the equilibrium constants for combination with cupric ethylacetoacetate is similar to that observed by Sacconi, Lombardo and Paoletti[3] for co-ordination to nickel, including the low value for α-picoline, no doubt due to steric interference by the methyl group. The much lower stability of the acetylacetonate adducts suggests that the copper atom in these carries a much smaller net charge, as would be expected from general considerations of structure and from the polarographic results of Calvin and Bailes[8], though a small part of the effect may be due to the change of solvent.

The use of *cyclo*hexane as solvent eliminates any possibility of co-ordination by the solvent and these stability constants thus share with those of Sacconi, Lombardo and Paoletti the unusual property of referring to a process of co-ordination uncomplicated by the displacement of co-ordinated solvent molecules, implicit in all equilibria observed in aqueous solution.

Detection and Estimation of Benzenoid Compounds by Chromatography

METHODS have frequently been described for the detection and estimation of heterocyclic compounds on chromatograms by ultra-violet photography[1-4]. These methods use a mercury discharge lamp suitably filtered. This type of lamp, however, yields predominantly the 253·7 mμ mercury line and is only suitable for compounds having a considerable absorption at this wave-length. With the benzenoid ring class of compounds, the absorption maxima are generally between 265 mμ and 285 mμ, frequently with the trough near the 253·7 mμ line. Consequently, in order to detect these compounds by a similar technique, a different source of light is necessary.

Table 1

Compound	Absorption	
	Maximum (mμ)	Minimum (mμ)
cis-trans β-Chloromuconic acid	264	—
cis-cis Muconic acid	259	—
2-Hydroxy-4-chlorophenoxyacetic acid	283	255
4-Chloroguiacol	283	255
p-Chlorophenoxyacetic acid	280	247
4-Chlorocatechol	284	250

A hydrogen discharge lamp, similar to that used in the 'Unicam' quartz spectrophotometer (*S.P.* 500), was used as the source of ultra-violet light, utilizing the stabilized power unit of the *S.P.* 500. It was necessary to reduce the continuous spectrum of the hydrogen lamp to a band of 260–300 mμ with a peak at 285 mμ. An aqueous nickel sulphate solution (27·5 gm./200 ml.) has a high transmission of light between 220 mμ and 360 mμ and also above 400 mμ. An aqueous solution of quinine sulphate (125 mgm./250 ml. + 1 drop of sulphuric acid) transmits a band between 260 mμ and 290 mμ and also above 360 mμ. A mixture of three parts nickel sulphate solution to one part of quinine sulphate combined with a 'Chance' *OX* 7 filter, to cut off the visible light, provided a suitable stable filter system. The transmission curves of the component filters are shown in Fig. 1. The filter compartment comprised of the *OX* 7 filter as one face and a quartz plate as the other (3 in. × 3 in., optical faces) with a rubber cushioned 'Perspex' 'U' (4 in. × 4 in. × ½ in., diameter of central hole being 2 in.) separating the two. Two brass plates (4 in. × 4 in. × ¼ in.) with 2-in. diameter holes cut centrally, also rubber-cushioned, were placed at each end of the compartment and the whole bolted together at the corners with brass bolts to a suitable lamp

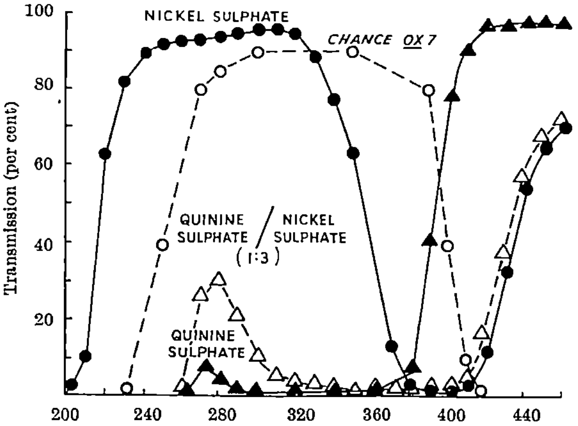

Fig. 1. Transmission spectra of filters

housing. A heat–light baffle was made at the top of the lamp housing. The chromatogram from which the solvent system had been completely removed was stretched tightly over Ilford bromide document paper No. 60 and exposed to the light source. The exposure was approximately 30 sec. at 2 ft. Table 1 shows the absorption maxima and minima of some metabolic intermediates which were resolved in this manner[5-7]. It was possible to trace the spots on to the chromatogram, and after elution estimate them quantitatively in the ultra-violet spectrophotometer. 0·10 μmole of *cis-trans* β-chloromuconic acid, 1 μmole of 2-hydroxy-4-chlorophenoxyacetic acid and 1 μmole 4-chlorocatechol could be estimated in this way.

Melting Point and Sublimation of Molybdenum Disulphide

Molybdenum disulphide has until recently been reported as having a melting point[1] of 1,185° C. In 1956, however, Zelikman and Belyaevskaya[2] reported that samples of molybdenum sulphide did not melt at temperatures up to 1,350°, and only those which had been heated to temperatures in excess of 1,650° C. showed any (microscopic) signs of melting. The purpose of the present communication is to report experiments made in connexion with the preparation of clean molybdenum disulphide surfaces, which are relevant to the question of the melting point of the material.

By heating pure powdered molybdenum disulphide, suspended from a quartz spiral, *in vacuo*, plots of weight vs. temperature were obtained. The sample was purchased from the Alpha Molykote Corp. of Stamford, Conn., and contained 58·9 per cent molybdenum (calc. for molybdenum disulphide, 60·0 per cent). The sensitivity of the system was about 0·5 per cent of the sample weight and the ultimate vacuum in the system better than 10^{-6} mm. mercury. The heated zone of the apparatus was made from fused quartz. Apart from losses in weight at lower temperatures due to the evolution of material adsorbed from the atmosphere, the weight losses of interest are one of about 2 per cent in the temperature 850–950° C., which presumably corresponds with the volatilization of surface molybdic oxide, and a much larger one at temperatures in excess of 1,050° C., when a brown film begins to cover the inside of the apparatus. This film, when examined by the electron-diffraction technique, proved to be hexagonal molybdenum disulphide. The weight loss at this highest temperature was proportional to the time the specimen was held at that temperature. The residual solid was observed to be a loose sinter of no great mechanical strength, even after the sample had been held at 1,250° C. for 4 hr. At this temperature, the quartz wall was attacked by the deposited molybdenum disulphide, with the formation of a zone of powdered silica. The net result was the ultimate devitrification of the apparatus.

Table 1

Sample No.	Temperature, °C (± 20°) at which sample was taken	Gas pressure (μ)	Composition in sample bulb
1	1,000	2	CO or N_2 + a little H_2
2	1,200	11	CO or N_2
3	1,450	0·03	CO or N_2
(Sample was allowed to cool and experiment recommenced after the system had been pumped down (once more, hard))			
4	980	2	95 per cent CO 5 per cent H_2
5	1,400	0·8	85 per cent CO 15 per cent H_2
6	1,510	1	88 per cent CO 12 per cent H_2
7	1,720	0·5	85 per cent CO 15 per cent H_2
8	1,800	0·3	75 per cent CO 25 per cent H_2

A pair of specimens of pure natural massive molybdenite (locality Kingsgate, New South Wales, molybdenum obs. 58·4 per cent, no other metals present to the extent of more than a trace except lead, 0·01 per cent) were mounted by molybdenum bolts to molybdenum leads in such a way that the resistance, and hence the continuity, of the specimens could be checked. A molybdenum crucible was arranged around the specimens, the assembly placed in a quartz envelope, and attached to a high-vacuum pumping system via a gas sample manifold. The specimens were heated inductively, and the evolved gases were sampled and afterwards analysed on a mass spectrometer (Table 1). Surprisingly, the gases contained no sulphur-bearing materials at all. Temperatures were measured using a calibrated disappearing-filament pyrometer, with suitable corrections for the emissivity of molybdenum metal as viewed through quartz. Quartz strip shields were used to prevent the formation of a continuous condensed film of the sample around the wall, which would have caused coupling of the radio-frequency field with the conducting deposit, and which also would have prevented accurate observation of the temperature of the crucible.

The specimens did not melt even when held at a temperature of 1,800±20° C. for 10 min. Consequently, the melting range of 1,650–1,700° reported by Zelikman and Belyaevskaya[2] cannot be real: their result may be due to reaction of the sample with its surroundings since they used graphite vessels. Such an artefact is certainly the cause of the very low early value of 450° C. due to Joly[3] for the onset of sublimation of molybdenite, which in this work occurred around 1,050° C. If molybdenum disulphide obeys the Tammann rule, that is, if it begins to sinter noticeably at a temperature about one-half of its absolute melting point[4], then it would be expected to have a melting point around 2,375° C.

I wish to thank J. Kelly for preparing the vacuum systems and F. J. Norton for the mass spectrometric gas analyses.

Alicyclicity and Smoke Emission of Coal

MUCH work has been done in the past on the smokiness or the smoke nuisance of coal during combustion, but mainly on its abatement. The fundamental causes of smoke emission have been little studied, though its obvious link with volatile matter and/or tar[1] has been known. Recent dehydrogenation studies[2,3] made by us leading to the determination of alicyclic carbon in coal have resulted in certain findings on the pyrolysis and combustion behaviour of dehydrogenated coals which obviously suggest that alicyclic bodies in coal are the main smoke-forming constituents.

It has been shown elsewhere[3] that dehydrogenated coals (for example, by Vesterberg's technique—dehydrogenation carried out with sulphur below the decomposition point of coal) do not yield any tar and that the char yield increases proportionately to the alicyclic carbon content of coal at the expense of tar-forming bodies. It has been shown[4] that alicyclic bodies in coal are primarily responsible for the formation of tar.

These findings naturally prompted us to study the combustion behaviour of the dehydrogenated coals. As the devolatilization of alicyclic bodies, that is, the tar-forming bodies, is completely inhibited on dehydrogenation, it was anticipated that pyrolysis of such bodies would also be avoided during combustion, resulting possibly in the smokeless burning of such coals. This was found to be so in the case of all dehydrogenated coals prepared from different ranks.

Table 1. ALICYCLICITY AND SMOKINESS OF COAL

Coal	On unit coal (per cent)			
	Carbon	Hydrogen	Alicyclic carbon*	'Smokiness'†
Assam	80·3	5·9	16·1	2·44
Jambad Bhowlah	80·6	5·4	13·7	2·25
Poniati	83·5	5·5	15·5	2·25
Laikdih‡	87·3	5·3	10·1	1·50
Pootki‡	88·0	5·3	11·2	1·40
Jharia, IX	90·7	4·7	5·5	0·87
Jharia, IX	90·4	4·6	3·6	0·75
Anthracite (South Wales)	93·2	3·5	nil	nil

* Data taken from earlier papers (refs. 2, 3 and 4).

† By 'smokiness' is meant here the soot and free carbon in the flue gas which was trapped and filtered off quantitatively in glass-wool and weighed. The experiments were carried out in a small muffle furnace under identical conditions of air-supply, that is, the ratio of air to the amount of volatiles was kept the same in all cases by adjusting the weight of coal.

‡ Vitrains.

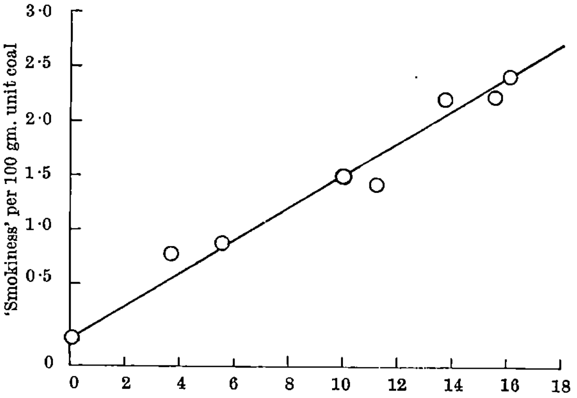

Fig. 1. Relation between alicyclicity and smoke emission of coal

Halogenation also has been found[5] to bring about the same type of dehydrogenation and stabilization of alicyclic carbon during subsequent pyrolysis. Such dehydrogenated coals are also smokeless during combustion. Prior treatment of coal with acids like sulphuric and phosphoric and certain other dehydrating agents like phosphorus pentoxide and potassium hydrogen sulphate also renders a coal smokeless without having to carbonize it. It has been found that during such treatment no tangible loss of carbon or hydrogen takes place, but apparently a reorganization (possibly condensation) of the alicyclic part in relation to the basic aromatic nucleus occurs whereby devolatilization of alicyclic bodies is completely inhibited[6].

Controlled oxidation[7] of any coal will also bring about a similar change.

It would appear, therefore, that smoke emission is primarily due to the alicyclic structures in coal and any process which can help stabilize such structure would make a coal smokeless.

Relative smokiness of different ranks of coal has been measured (Table 1) and is found to bear a linear relationship with alicyclic carbon content of the coals (Fig. 1). Anthracites and semi-anthracites contain very little or no alicyclic carbon, and hence they are smokeless. Semi-coke or char are smokeless fuel as these carbonized products do not contain any alicyclic structure. Thus it is possible to make a smokeless fuel from any coal without having to carbonize it. The inhibition of tar formation on oxidation of coals has been known for a long time; but the fundamental causes have become evident from our studies on dehydrogenation of coals.

Density of Water sorbed on Montmorillonite

A RECENT communication by R. C. Mackenzie[1] on the above subject directs attention to some density measurements made on Wyoming bentonite pastes[2,3]. A confirmatory set of measurements has also since appeared[4]. Although the results were not obtained under exactly comparable conditions or on exactly comparable material, they exhibit adequate internal consistency. The divergences seem to arise in the authors' discussions.

Fig. 1 presents a plot of density versus weight per cent of oven-dry bentonite in the pastes reduced from the tabulations of De Wit and Arens[2], apparently taken at 20° C., and of Oakes[4], taken at 30° C. Levels of accuracy and of temperatures of observation are sufficiently close for points from the two sources to lie on a smooth curve. It also essentially includes the observations of Anderson and Low[3] throughout the range of their results.

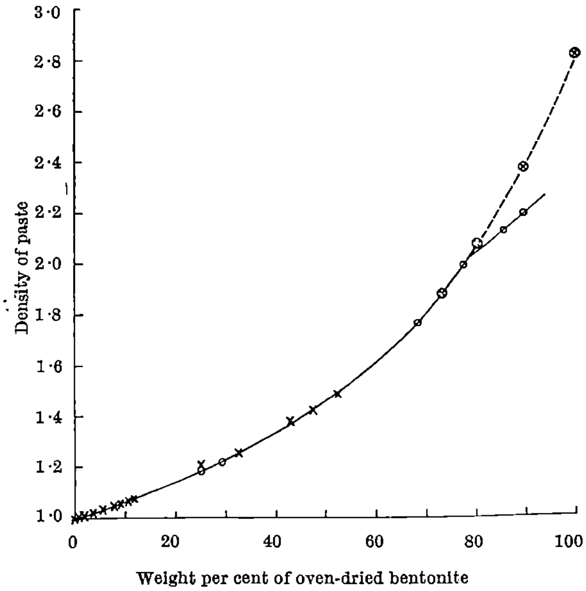

Fig. 1. Densities of Wyoming bentonite pastes. ×, Oakes's results; O, De Wit and Arens's results; ⊗, approximate positions of X-ray densities for the water contents at which the bentonites exhibit three, two and one layers of hydration water, and for the bare lamellæ. The dashed extrapolation indicates the trend which a curve would follow if no porosity were consequent to the shape of independent flakes

Montmorillonite, the main mineral constituent of bentonite, is abundantly documented as having a remarkable laminar structure in which individual laminæ are more or less independent. In the absence of an enveloping medium, the density of an aggregate of independent flakes makes up a fraction of the true density roughly comparable to the 91 per cent of a given volume which can be occupied by a packed set of equal disks. That is, the aggregate volume per disk is 110 per cent of the volume of a single disk. In an excess of enveloping medium, each lamina occupies only its own characteristic volume.

The unit dimensions, based on Pézerat and Méring's[5] X-ray measurement of parameters within layers, and the structural formula of montmorillonite in analysed Wyoming bentonite, afford a calculated density of 2·83 for the laminæ alone. This is in suitable agreement with the observed density of pyrophyllite, in which layers of nearly identical dimensions and compositions are not independent, and is about 1·1 times the 'density' measurements obtained from dry montmorillonite.

Table 1

Conc. wt. per cent oven-dry bentonite in paste	Density determination		Average specific volume of water	Apparent specific volume of bound water, if bound water equals 0·3 the weight of bentonite
	Oakes	De Wit and Arens		
0·000	0·99564	(0·998)	1·0044	
0·982	1·00155		1·0048

77·9		2·001	1·02	
85·75		2·134	1·16	
89·60		2·199	1·33	

* Note departure from curve in Fig. 1

In Table 1, apparent average specific volumes of water in the several pastes cited are arrived at by simple subtraction of the volumes of the montmorillonite laminæ present from the total volume.

It is also frequently inferred that montmorillonite laminæ rather strongly control up to about one-third of their own weight in water molecules (cf. Bradley[6]). If normal specific volume be assumed for the residue of water in these pastes which is not so controlled, the apparent specific volume of controlled water may be calculated and is listed for several cases in Table 1.

In Oakes's pastes the exchange base present was sodium ion, and it must be presumed that these ions were associated mainly with the bound fraction. Their abundance with respect to bound water is about 8 per cent by weight, or 2 per cent by volume. Allowance of 2 per cent positive error for each of the sodium ion paste entries still leaves an average of about 1·04 for the specific volume of the bound water.

The more elegant procedure of Anderson and Low[3] avoids the rather complicated assumptions outlined above by measuring the rate of change of volume of a paste as water is expressed from it. At the level of 62·5 per cent solids (Fig. 1), they found apparent specific volumes for the water being expressed of 1·02–1·03, in excellent agreement with the calculated volumes at comparable solid content in Table 1.

In the region 75 per cent solids (77 per cent if the estimate for bound water of 0·3 by weight of the solid were assumed to be a fixed quantity) the water becomes insufficient to constitute a continuous phase. Apparent specific volumes for water then lose their meaning, and the density determinations depart gradually from the smooth 'theoretical' curve toward the bulk density of packed solid disks. Instead of the 'apparent molar volumes' for the last two entries in Table 1, apparent porosities may be estimated, and they are about 3 per cent and about 6 per cent respectively. Apparent porosities for cited weighed oven-dried aggregates are about 10–15 per cent.

[6] Bradley, W. F., Proc. Fourth Nat. Conf. on Clays and Clay Minerals, 41 (Nat. Acad. Sci.—Nat. Res. Council Pub. No. 456, 1956).

DR. BRADLEY has very successfully correlated data from diverse fields of study to show the essential agreement in density determinations on montmorillonite pastes. In this connexion it is interesting to note that early determinations carried out at this Institute, and referred to previously[1], fall quite nicely on the spur of the curve above 77 per cent solids.

In considering the extrapolated part of the curve, however, it must be remembered that montmorillonite oven-dried even at 135° C. (as used by Oakes[2]) always contains some residual sorbed moisture (the amount may be a few per cent[3]), and hence it is rather surprising that Dr. Bradley's density value for dry montmorillonite (calculated from X-ray and chemical data) fits the curve so closely. One would have expected some slight discrepancy in view of the fact that the pastes involved were made up with oven-dry montmorillonite. A montmorillonite (Wyoming bentonite) for which we have X-ray and accurate chemical data[3] gives a calculated density of 2·78—somewhat lower than Dr. Bradley's value, and the true hypothetical value for 100 per cent oven-dry montmorillonite would be expected to be even lower. The value for dry montmorillonite is somewhat critical in estimating the specific volume of the 'bound' water and, furthermore, it might be remarked that the bulk specific volume of the 'bound' water would be expected to vary with the exchangeable ion and may not be the specific volume of all fractions of this water. One wonders, too, whether it would necessarily be expected that the extrapolated density : montmorillonite-concentration curve need be a smooth continuation of that obtained in the lower concentration regions.

In view of the difficulties in assessment of the final part of the curve (more than 77 per cent solids) there is, to my mind, as yet no unequivocal evidence from density measurements as to the configuration of the *first* amounts of water sorbed by montmorillonite.

The divergences in discussion mentioned by Dr. Bradley surely arise from the fact that different authors have been considering the interpretation of results from rather different points of view. In the lower solids-concentration region all are agreed that density measurements can give an overall estimate of the density of the water present, the essential accuracy of which is clearly demonstrated by the elegant experiments of Anderson and Low[4].

Structure and Mode of Action of the Contact γ-Aluminium Oxide/Platinum

ON the hypothesis of the free-radical structure of heterogeneous catalysts[1,2], the mechanism of many catalytic reactions has been deduced in recent years[3]. In order to explain the action of the γ-aluminium oxide (Al_2O_3)/platinum contact, the structure of the radical γ-Al_2O_3 (ref. 4) as an active transient phase with structural defects should be considered. The model formula of the non-active oxide Al_2O_3 can be represented as follows : $O{=}Al{-}O{-}Al{=}O$. The active γ-Al_2O_3 contains the radicals : $O{=}Al{-}$ and $-O{-}Al{=}O$. Though this formula could be written in several similar forms, because Al_2O_3 is a macromolecular compound, only two types of radical can be expected, namely, $R{=}Al{-}$ (electron donor) and $R{=}Al{-}O{-}$ (electron acceptor).

Since the contact γ-aluminium oxide/platinum is obtained as a product of the action of chloroplatinic acid on active γ-aluminium oxide, there is a possibility of exchange between the two compounds, according to the equation :

$$(O{=}Al{-}\ \ {-}O{-}Al{=}O)_2 + 2H^+PtCl_6^{2-} \rightleftharpoons (O{=}Al{-}OH)_2 + 2(AlO)^+PtCl_6^{2-}$$

Under the influence of an excess of chloroplatinic acid, the dissociation of aluminium–platinum compound goes backwards; this can also be explained by the action of the active γ-aluminium oxide as a chromatographic column[5]. In the stream of hydrogen the undissociated $(AlO)_2PtCl_6$ undergoes reduction as follows :

$$(AlO)_2PtCl_6 + 3H_2 \rightarrow (O{=}Al{-})_2 + Pt + 6HCl$$

and as a result of this the radical $O{=}Al{-}$ appears, which is necessary as an important link in the chain of reactions leading to the hydrogenation of benzene. Thus the active γ-aluminium oxide acquires electron donor properties. But when the concentration of chloroplatinic acid is small, the complete suppression of the dissociation of $2(AlO)^+PtCl_6^{2-}$ is doubtful, this compound being able, under the influence of hydrogen, to retain its ionic form. This checks the regeneration of the primary radical $O{=}Al{-}$, according to the reaction :

$$2(AlO)^+PtCl_6^{2-} + 2H_2 \rightarrow 2(AlO)^+2Cl^- + 4HCl + Pt$$

This explains why γ-aluminium oxide/platinum contacts with small contents of platinum lose their activity quickly[6], because, in my opinion, in the absence of sufficient numbers of $O{=}Al{-}$ radicals, platinum only activates hydrogen so long as it is saturated with it or with a hydrogen compound (*cyclo*hexane) :

$$Pt + H_2 \rightarrow Pt/H + H$$

But when the radical $O{=}Al{-}$ appears and co-operates with metallic platinum, then platinum, passing into the atomic state, can also make use of the electrons of $O{=}Al{-}$ and of molecular hydrogen in turn, so that hydrogen is activated. In consequence of this the hydrogen electron, together with its proton, is as it were thrown aside after the electron arising from the $O{=}Al{-}$ radical becomes available, and so on in a constantly repeating rhythm[7]. The mechanism of the reaction of hydrogenation of benzene at the γ-aluminium oxide/platinum contact can be represented in the form of a chain reaction, which is accompanied by a migration of electrons[7].

$$O{=}Al{-} + Pt + H_2 \rightarrow O{=}Al{-} \ldots Pt \ldots H + H$$
$$3\,(O{=}Al{-} \ldots Pt \ldots H) + 3H + C_6H_6 \rightarrow C_6H_{12} + 3\,(O{=}Al{-} \ldots Pt), \text{etc.}$$

The γ-aluminium oxide/platinum contacts are prepared by mixing a suspension of the oxide with the solution of chloroplatinic acid; in consequence the acid is adsorbed on the surface of aluminium oxide. The method described by Trzebiatowski and Kubicka[6] produces less active catalyst than that of Kobozev and co-workers[8]. It should be made clear that in the first case the authors worked at a higher temperature-range of the mixture (on a water-bath), while in the second case all operations are carried out at room temperature. It is believed that the O=Al— radicals disappear more easily at higher temperatures, transforming themselves into cations $(AlO)^+$ according to the first reaction given above.

GEOLOGY and MINERALOGY

A Marine Transgression of Boreal Age in the Southernmost Part of Norway

IN the summer of 1956 the Quaternary history of a number of trough-shaped basins was investigated in the area between Lindesnes and Kristiansand. In one such basin, at Dostad in the innermost part of Hartmarkfjord (lat. 58° 02′ N., long. 7° 38′ E.), a mire was found at a depth of about 1·5 m., lying between layers of marine sediments (Fig. 1). The basin is very well sheltered from the sea by, among other things, a rock threshold which is about 2 m. above present sea-level. The mire is 1·5–1·7 m. thick.

A variation in the proportions of marine to freshwater diatoms was observed in the mire. The 50 cm. directly above the marine clay (*e*) and including the gyttja (*d*) contains only freshwater forms. Farther up, a few salt water forms appear together with freshwater species. The proportions of salt water forms increase upwards until at the top only marine forms are present.

The mire rests on marine clay and is covered by marine diatomaceous earth (quantities of *Melosira* (*Paralia*) *sulcata* and many *Navicula lyrata* types) on top. It seems probable that these diatoms have actually lived here.

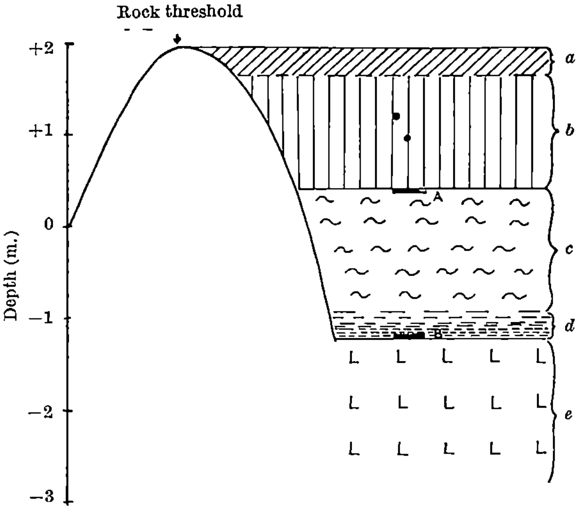

Fig. 1. Vertical scale exaggerated. *a*, Cultivated soil; *b*, marine diatomaceous earth; *c*, 'peat'; *d*, freshwater gyttja; *e*, marine clay

Samples were collected for pollen and diatom analyses by means of a Hiller peat sampler. Miss Kari Egede Larssen, of the Norwegian Geological Survey, has been kind enough to carry out pollen analyses of samples from the base and the top layers of the mire. Both samples contain considerable quantities of *Corylus* (15–17·5 per cent), but practically no *Alnus* pollen. In addition, many macroscopic fossils were found, among which were nuts and leaves of *Corylus* and tree branches. Miss Egede Larssen states that in all probability the samples are of boreal age.

For carbon-14 datings, horizontal slices of the 'peat' 2–3 cm. thick were collected. One was taken from the top of the mire and one from the bottom (Fig. 1, *A* and *B*). The datings have been carried out by the Radiological Dating Laboratory at the Norwegian Institute of Technology in Trondhjem. The ages of the samples were found to be 8,770 ± 100 years (B.P.) and 9,410 ± 220 years (B.P.) respectively.

This part of Fennoscandia is peripherically situated with respect to the rise of the land after the last Ice Age and the marine transgressions could occur because eustatic movements would easily be stronger than the isostatic movement.

Referring to the above-mentioned datings, one must accept that the Dostad basin was isolated from the sea because of a regression which occurred approximately 9,400 years ago. A rich vegetation came into existence and lasted until approximately 8,800 years ago, when a transgression of the sea, probably eustatic in origin, drowned this boreal vegetation.

Such a great amount of marine diatomaceous earth as was formed afterwards has, apparently, never previously been recorded in Norway. Marine diatomaceous earth has been observed in Sweden[1].

Several Swedish authors[2,3] have given diagrammatic representations of the movement of the shoreline in the Gothenburg area, and these show that a transgression began to make itself clearly apparent about 7000 B.C. One of these authors repeats this again in a later publication[4]. The "time of sinking of the land" must in any event have begun before *Alnus*, *Quercus* and *Tilia*, etc., appeared in the region[1] (northern Halland). Fromm is quoted[5] as having found, from the pollen analysis results of varved sediments, that the *Alnus* curve began about 6300 B.C. This dating is valid for southern Sweden. A great peat column at Adak in Northern Sweden has been dated by the carbon-14 method, thus placing the beginning of the *Alnus* curve at 6620±125 B.C.[5]. The pollen analysis from the upper part of the mire (Fig. 1,*c*) indicates that its age is apparently not far from the time when the *Alnus* curve began. This correlates very well with the radiological dating from Sweden.

Marine sediments resting directly upon a boreal terrestrial deposit have apparently not been previously reported in Norway. The occurrence of marine diatoms, as described above, indicates that sea-level was not far below the rock threshold and that waves were able to break over it, for example, during storms and exceptionally high-water levels. The minimum level of the boreal shore-line, judging by the evidence of the diatoms, was not far from the present sea-level in the area. However, work on a graph of the movement of the shore-line is being carried out at present, and more detailed results will be published later.

Olivine-Spinel Transformation

IN the light of A. E. Ringwood's recent synthesis of a spinel form of fayalite (private communication), Fe_2SiO_4 (the iron end-member of the fayalite–forsterite mixtures which comprise the bulk of natural olivines), it seemed worth while to attempt a synthesis of a spinel form of forsterite, Mg_2SiO_4. Ringwood prepared the fayalite-spinel at about 50 kilobars and 500° C., and his calculations indicated that the forsterite-spinel should become stable at about 100 kilobars and 500° C. It is possible that olivine is abundant in deeper layers of the Earth (50–1,000 km.) and hence some knowledge of its phase transitions would be of geological interest[1].

To study these possible phase transitions, appropriate mixtures of dry and hydrous oxides were loaded into a carbon capsule contained in a high-pressure, high-temperature apparatus. After the pressure on the capsule was increased to the desired level, it was electrically heated to about 550° C. for about 20 min. (Crystals of 10 or 20μ average diameter formed in 5 min.) Then the sample was quenched to room temperature and the pressure was reduced to atmospheric. In this way any phases formed at high pressure would tend to be preserved. Various hydrated phases formed if the maximum temperature did not exceed about 500° C.

Table 1

Charge	Pressure (kilobars)	Products identified
2 $Mg(OH)_2+SiO_2 \cdot nH_2O$	95–130	Forsterite
$Fe+Fe_3O_4+SiO_2 \cdot nH_2O$	110	Ringwood's fayalite-spinel (Debye–Scherrer patterns agree)
$Fe+Fe_3O_4+MgO+SiO_2 \cdot nH_2O$	110	Forsterite, fayalite-spinel
Hawaiian olivine	93–(hot)	Olivine melted and frozen this run. Olivine recovered
Moist Hawaiian olivine	90–110	Olivine unchanged
2 $Mg(OH)_2+0{\cdot}9\ SiO_2+0{\cdot}1\ GeO_2+H_2O$	110	Forsterite
2 $Mg(OH)_2+SiO_2 \cdot nH_2O$ +5 per cent Ni_2GeO_4	110	Forsterite
2 $NiO \cdot SiO_2 \cdot nH_2O$	90–110	Nickel forsterite (no spinel)
2 $ZnO \cdot SiO_2 \cdot nH_2O$	90	New phase, r.i. 1·78, biaxial. No spinel

Table 1 summarizes the results of these experiments.

Thus no other olivinic spinel other than Ringwood's fayalite-spinel formed in these experiments. Perhaps higher pressures are necessary. This work will be continued.

I am indebted to A. E. Ringwood and Prof. F. Birch for stimulating the work on this problem and for providing some of the oxide mixtures.

PALÆOMAGNETISM

Late Tertiary Geomagnetic Field in North-western Canada

THE fundamental assumption made in interpreting palæomagnetic results is that the average geomagnetic field corresponds to that of a central axial dipole. This communication reports on some palæomagnetic results which support this assumption and which were made on Late Tertiary volcanic rocks, which were collected during the summer of 1955 from north-western Canada by field geologists of the Geological Survey of Canada from flat-lying, undisturbed, vesicular basalts.

Forty-eight samples were collected from four different localities. The largest suite, twenty-nine amples, was collected by J. O. Wheeler from lavas exposed near Whitehorse, Yukon, at a latitude of 60·5° N. and longitude of 135·0° W. Another nine samples were collected by W. H. Poole near Wolf Lake, Yukon, at 60·0° N. and 130·5° W. L. H. Green collected six samples near Selkirk, Yukon, at 63·0° N. and 138·0° W., and J. D. Aitken collected four samples near Surprise Lake, British Columbia, at 59·5° N. and 134·0° W.

These samples were measured on a magnetometer of the rock generator type at the Geological Survey of Canada during 1958. The results of these measurements are shown in Fig. 1 on a stereographic projection, full and open circles representing north poles on the lower and upper hemispheres respectively. All the rocks collected by Wheeler and Green are reversely magnetized while the rest are normal except for two of Poole's samples, which are almost horizontally polarized.

The mean direction of these rock samples has been computed by reversing all the reversely polarized rocks and adding them to the normal ones. The two horizontally polarized samples are considered to be anomalous, due perhaps to magnetization caused by lightning, and have not been included in the statistical analysis. The mean direction, *H*, with its Fisher statistics, has been listed in Table 1, where it is compared with the field, *F*, produced by a central axial dipole and the present geomagnetic field, *F′*, at

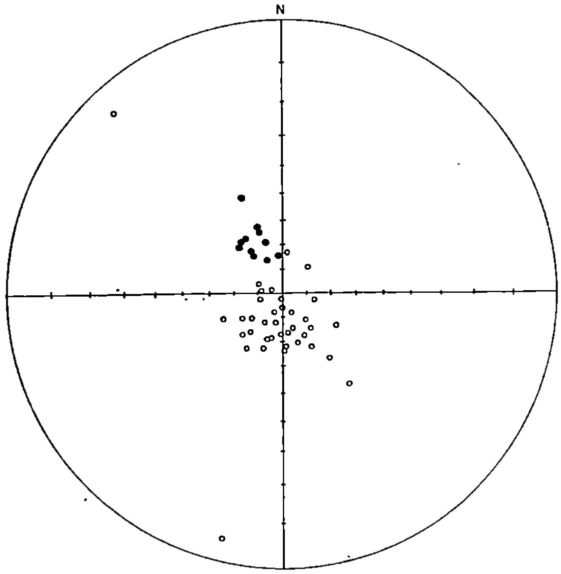

Fig. 1. Stereographic projection of palæomagnetic directions of Late Tertiary volcanics from north-western Canada. ●, North pole on lower hemisphere; ○, north pole on upper hemisphere

60·0° N. and 135·0° W. The λ's are the angles between the palæomagnetic direction, *H*, and *F* and *F′*.

Table 1 shows that the mean palæomagnetic direction of these Late Tertiary rocks is equivalent to the axial dipole field expected at this locality and is significantly different from the Earth's present field. These results are therefore further evidence to support the basic assumption of most geophysical interpretations of palæomagnetism, namely, the average magnetic field of the Earth is due to a geocentric axial dipole.

Table 1

	H	*F*	*F′*
D	348·5	0·0°	31·0°
I	+ 75·0	+ 74·0°	+ 76·0°

PHYSICAL SCIENCES

Simultaneous Occurrence of Sub-Visual Auroræ and Radio Noise Bursts on 4·6 kc./s.

SINCE July 1958 the red oxygen (6300 A.) airglow has been recorded at Camden, near Sydney (geomagnetic latitude 42° S.), with a sky-scanning photometer. This instrument has been described by St. Amand[1]. These observations frequently detected greatly enhanced emission towards the south, and less often structures such as arcs and rays. We interpret these as auroræ, usually sub-visual, though on seven nights auroræ were seen.

Table 1. OCCURRENCE AND ABSENCE OF NOISE ON 4·6 KC./S. AND AURORÆ

		Noise on 4·6 kc./s.	
		Yes	No
Auroræ	Yes	18	2
	No	6	27

During the same period, radio noise on 4·6 kc./s. was continuously recorded by a method[2] which largely eliminates impulsive atmospheric and industrial interference. These observations[3] frequently detected distinct noise bursts, many times stronger than the background and usually lasting a few hours.

A comparison of the radio and nightglow records shows that there is a definite correlation between the two. Of 53 nights of simultaneous observations of noise and airglow between June and December 1958, noise bursts and sub-auroræ were recorded during the same hours on 18 nights. On 27 nights neither noise nor sub-auroræ were recorded; on 6 nights noise was recorded in the absence of any auroral pattern in the airglow, while on two occasions auroræ were recorded without any noise bursts. This is summarized in Table 1.

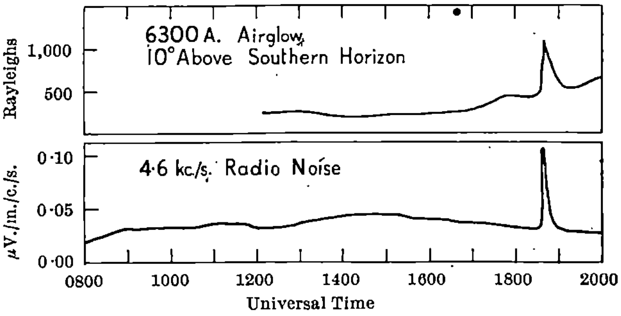

Fig. 1. Noise and auroral burst observed on July 21, 1958

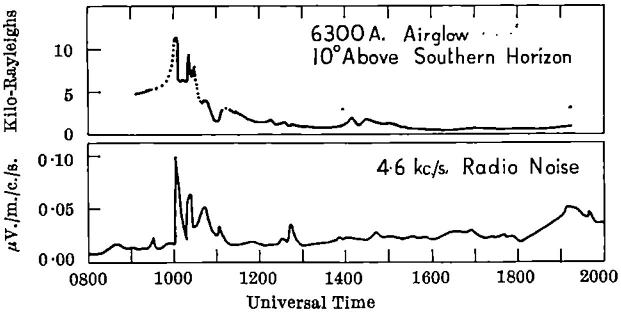

Fig. 2. Airglow and noise records for August 27, 1958. No red airglow observations were made during those periods for which the trace is dotted

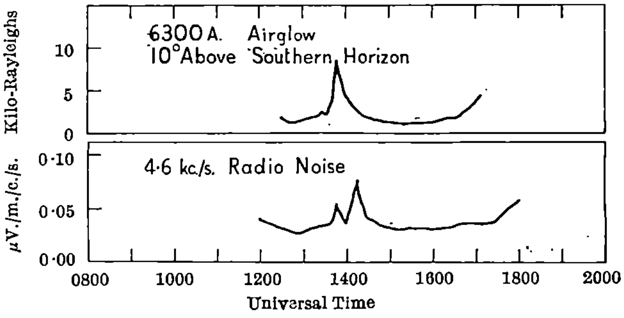

Fig. 3. Noise and airglow records for January 5, 1959

As might be expected, both phenomena are related to magnetic disturbance. They tend to occur when the disturbance index (K) reaches or exceeds 5.

On a few nights the fluctuations of noise and light intensities have shown a minute-to-minute correspondence (Figs. 1–3). This suggests that they may both be directly generated by the same phenomena, possibly the entry into the atmosphere of proton or electron streams.

However, there is in general no exact correspondence between the two; as Table 1 shows, one is occasionally observed without the other. The radio noise, unlike the auroral light, should be detectable even when its apparent source lies below the horizon. This probably accounts for much of the looseness in the association between the two, and for the occasional observations of noise without auroræ. However, the two cases of auroræ without accompanying radio noise cannot be explained in this manner. If the auroræ are caused by proton or electron streams, then it follows that such streams do not always generate radio noise.

This work forms part of the research programme of the Upper Atmosphere Section of the Commonwealth Scientific and Industrial Research Organization.

Dual Pumping Speeds of Some Ionization Pumps

In recent years the phenomenon of ion pumping in ionization gauges has received widespread attention. Work in many laboratories has shown that in an ionization gauge, activated gas molecules interact with the glass walls of the tube and are removed from the gas phase at a rate depending largely upon the pumping history of the gauge. Alpert[1], Nottingham[2] and others have shown that in the Bayard–Alpert form of gauge, the glass walls assume an electrical potential, slightly negative with respect to the cathode delivering primary electrons, and the pumping action of the gauge is due largely to ions which acquire a high kinetic energy and are driven into the walls.

Comsa and Musa[3,4] have described an ion pump in which ions are collected by the glass walls alone—there is no specific ion collector in their tube—and have calculated that the glass walls acquire a potential, determined by the equality of electron and ion bombardment, about 5 V. negative with respect to the cathode. The pumping speed of such a tube was reported to be 0·03 l./sec./m.amp.

However, experiments performed during the past three years in these laboratories on Bayard–Alpert gauges have revealed that such gauges possess two distinct pumping speeds, one about five times the other, and it has been suggested[5,6] that the electrical potential of the inner surface of the glass walls, which, it has been proposed, assumes a value approximating to either cathode or anode potential, determines at which speed the gauge shall pump. Later work on a gauge of similar design to that of Comsa and Musa has shown that this type of gauge also possesses two distinct speeds and that the wall potential can assume either of the two aforementioned values.

The potential of the inner glass surface was measured by surrounding the gauge envelope with a metal sheath which was connected via any of a number of capacitors of known value to ground. The voltage appearing upon the sheath was applied to an electrometer amplifier. The approximate voltage on the inner glass surface was then deduced from a knowledge of the capacitance of the gauge-sheath system (approx. 50 pF. as measured with a similar tube and sheath).

These measurements showed that if the glass potential approximated to that of the cathode the gauge pumped relatively quickly, but if the potential was high ($\sim$ 200 V. in our estimation) there was only a slight pumping action. In this latter condition probably few ions could reach the walls. When the gauge had been outgassed for a short time only, soon after commencing experiments, it was found possible to control the wall potential. If the electron emission was initiated before applying anode potential, the walls become stabilized at cathode potential. If, however, anode potential was applied before activating the filament, the walls became charged positively. After a number of outgassing cycles (a total of about 10 hr. at 400° C.) had been performed it was observed that no control could be exercised over the wall potential, stabilization occurring at cathode potential only.

As pointed out by Comsa and Musa, the walls become stabilized at cathode potential when the primary electron and ion currents balance, but it is believed that a second stabilization potential occurs at which the primary electron current is balanced by a current of secondary electrons emitted from the glass[7] (at about 200 V. in our experiments). When the glass is comparatively new and contains much occluded gas, the second stabilization potential can be obtained since the secondary emission coefficient of the glass can exceed unity, so allowing a current balance. When the glass is well outgassed there is evidence[8,9] to show that this coefficient will fall and stabilization at the higher potential becomes impossible. It is probable that Comsa and Musa observed one pumping action only, since they always activated the filament before applying any accelerating potentials and their outgassing techniques were stringent.

In this work a dynamic vacuum system[5,10] has been used so that the gas pressure in the experimental tube ($1{\cdot}0 \times 10^{-5}$ mm. mercury of argon) remained constant. Subsequent desorption of the pumped gas by heating the gauge enabled an evaluation of the speeds of the gauge to be made. These were: (1) when the glass became stabilized at -5 V. (approximately cathode potential), speed, 0·0003 l./sec./m.amp.; (2) when the glass became stabilized at $+$ 200 V. (approximately anode potential), speed, 0·00005 l./sec./m.amp.

The rate of ionic bombardment of the walls was determined in a gauge which included a cylindrical ion collector close to the walls, and it was shown that the higher of the above speeds corresponds to an ion clean-up efficiency of about 10 per cent.

In conclusion, it can be stated that an ion pump of the design proposed by Cosma and Musa inherently possesses two pumping speeds and in the early stages of use of this pump, especially if the pump has not been well outgassed, either speed can be obtained by a suitable electrode potential switching sequence. The duality of pumping speeds has been found to be a result of charging of the glass walls to either approximately cathode or anode potential.

Evidence for a Variable Long-range Order in Nearly Anhydrous Gamma Alumina

THE nature of the cubic or nearly cubic alumina called γ- or η-Al_2O_3 has been the subject of much speculation. Its structural similarity to the spinels has been known for many years[1–3] and led to the view that γ-Al_2O_3 is a defect structure which can be written $Al_{21\frac{1}{3}}\square_{2\frac{2}{3}}O_{32}$ with 21⅓ aluminium ions occupying statistically 24 cation sites in the spinel structure.

The recognition that γ-Al_2O_3 is frequently not a fully dehydrated alumina led de Boer and Houben[4] to suggest that 'water' may be an integral part of the structure and that an ideal formula may be $H\,Al_5O_8$ analogous to the spinels $Li\,Al_5O_8$ and $Li\,Fe_5O_8$ (see ref. 5). In these structures the lithium ions occupy particular positions in the lattice and therefore one might expect that if γ-Al_2O_3 is really $H\,Al_5O_8$, the hydrogen ions (or more likely the OH ions) likewise will occupy particular positions.

Saalfeld[6] has discussed the dehydration of gibbsite to boehmite and the subsequent formation of a nearly anhydrous alumina. The reactions are orderly in a crystallographic sense and the resulting γ-alumina is shown to be tetragonal with $a = b = 7{\cdot}95$ A. and $c = 7{\cdot}79$ A. We have found confirmation of this result in the course of studying the dehydration kinetics of a well-crystallized gibbsite. The nearly anhydrous alumina yielded a double peak in the position of the strong (400) spinel reflexion with components $d = 1{\cdot}98$ and $1{\cdot}95$ A. The longer spacing gives the more intense reflexion and corresponds to (400) and (040) with $a = b = 7{\cdot}96$ A. and the shorter spacing corresponds to (004) with $c = 7{\cdot}80$ A.

One may reasonably surmise that if dehydration occurs slowly from well-crystallized material, the ordered tetragonal structure is formed. This appears to be the γ-alumina of Stumpf[7] and Russell[8]. When dehydration takes place in a less orderly manner or from less favourable starting materials, then a statistically cubic material is formed which gives the spinel-type X-ray pattern.

We have obtained additional evidence for structural order in nearly anhydrous alumina prepared by slow dehydration of gibbsite. When the dehydration is carried beyond about 90 per cent of completion, a long spacing of the order of 30–90 A. is reproducibly formed and is fairly stable to atmospheric conditions. The peak occurs in the region of $2\theta = 1$–$2°$, with copper $K\alpha$ radiation. The peak is observed first at about 80 per cent of complete dehydration but at this stage some boehmite still remains. Fig. 1 shows plots of diffracted intensity against 2θ and it is obvious that, as dehydration goes to completion, the diffraction peak moves to smaller 2θ values and finally is lost in the direct beam. Usually only one peak is observed, occasionally two can be observed, so that the long-range order arising from the residual 'water' is of a statistical character. The well-defined peaks shown in Fig. 1 were obtained by 12-hr. heat-treatments at successively higher temperatures up to about 500° C. Dehydration carried out directly at 450–500° C. gave poorer peaks, though they still occurred.

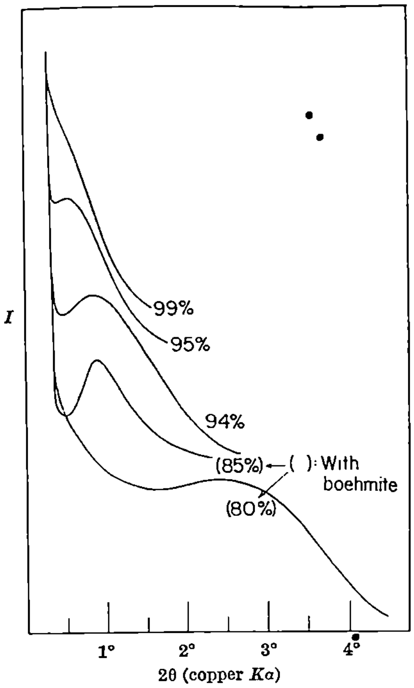

Fig. 1. Small-angle X-ray diffracted intensity from nearly anhydrous gamma-aluminas prepared from gibbsite. The percentage dehydration of the gibbsite is given for each curve. Note, however, that for 80 and 85 per cent dehydration, the remaining water is contained partly in residual boehmite

In terms of oxides, the ideal formula $H\,Al_5O_8$ is $Al_2O_3.\frac{1}{5}H_2O$ and corresponds to one-fifteenth of the initial 'water' content, that is, 6·7 or 93·3 per cent of complete dehydration, and the corresponding long spacing in Fig. 1 is about 65 A.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Monday, June 8

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Captain M. E. B. Banks, M.B.E.: "The Ascent of Rakaposhi".

Tuesday, June 9

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Papers.

University of London (at the Institute of Archæology, Inner Circle, Regent's Park, London, N.W.1), at 6 p.m.—Mr. S. S. Frere: "Animals in the Roman Empire".* (Last of six lectures on "Animals in Archæology".)

Tuesday, June 9—Thursday, June 11

National Physical Laboratory (at Teddington, Middlesex)—International Symposium on "Interferometry".

Wednesday, June 10

Commonwealth Fruits Council (joint meeting with the Food Group of the Society of Chemical Industry and the National Farmers' Union, at the Royal Commonwealth Society, 18 Northumberland Avenue, London, W.C.2), at 10 a.m.—Meeting on "The Utilization of Apples and Citrus Fruits".

Institute of Information Scientists (at the Shaftesbury Hotel, Monmouth Street, London, W.C.2), at 6 p.m.—Annual General Meeting. 7.15 p.m.—Dr. Alexander King: "The International Development of Scientific and Technical Information Services".

British Psychological Society, Social Psychology Section (in Room 425, Birkbeck College, Malet Street, London, W.C.1), at 8 p.m.—Mr. L. T. Wilkins: "Some Aspects of Research Strategy in the Field of Delinquency".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. R. S. Nyholm, F.R.S.: "Colour in Inorganic Chemistry".

Thursday, June 11

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. C. M. P. Johnson, Mr. G. A. Jones, Mr. W. R. Phillips and Prof. D. H. Wilkinson, F.R.S.: "A Study of the Levels in ^{19}F Following the Beta Decay of ^{19}O"; Mr. P. Dagley, Mr. M. A. Grace, Mr. J. M. Gregory and Mr. J. S. Hill: "Nuclear Alinement of Manganese-56".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Physics—The Secretary, The University, 38 North Bailey, Durham (June 12).

Chief Agricultural Research Officer (with a first- or second-class honours degree in natural science or agricultural science, considerable research experience in tropical agriculture, and an aptitude for the direction of research) with the Government of Western Nigeria, to plan, organize and develop the work of the Research Division of the Ministry of Agriculture and Natural Resources, assist in the formulation of a crop research policy, and to advise the Agricultural Extension Services of the Region on the application of research findings to crop production problems—The Official Secretary (Recruitment Branch), Office of the Commissioner for Western Nigeria, 178/202 Great Portland Street, London, W.1 (June 13).

Lecturer in Chemical Engineering—The Registrar, University College, Singleton Park, Swansea (June 15).

Lecturer (with veterinary qualifications and postgraduate research experience) in Animal Health in the Biochemistry and Nutrition Section of the Department of Agricultural Chemistry—The Secretary and Registrar, University College of North Wales, Bangor, North Wales (June 15).

Research Assistant (preferably with a knowledge of vacuum techniques or infra-red detectors) in the Department of Physics for work in the Optic Group on problems connected with the construction of filters for the infra-red region above 5 microns in wavelength—The Registrar, The University, Manchester 13 (June 15).

Tutorial Students in the Departments of Botany, Civil Engineering, Geology, Mathematics, Physics and Zoology—The Registrar, King's College, Strand, London, W.C.2 (June 15).

Scientific Officer or Senior Scientific Officer (male graduate with a first- or second-class honours degree in chemistry, and preferably with some postgraduate experience) in the Department of Spectrochemistry, for duties covering various aspects of emission spectrochemical analysis and trace element investigations—The Secretary, Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen (June 16).

Assistant Lecturer, and a Temporary Lecturer (medically qualified and preferably with experience in clinical bacteriology or virology) in the Department of Bacteriology—The Registrar, The University, Manchester (June 20).

Assistant Lecturer, Grade III (preferably with special qualifications and interests in plant physiology and biochemistry) in Botany—The Registrar, The University, Bristol 8 (June 20).

Demonstrator (preferably with an interest in histochemical or physiological aspects of comparative endocrinology) in Zoology—The Registrar, The University, Nottingham (June 20).

Junior Research Fellow in Pure Mathematics—The Registrar, The University, Sheffield (June 20).

Lecturer or Assistant Lecturer in Applied Mathematics—The Registrar, The University, Southampton (June 20).

Lecturer (with practical experience in the aircraft industry and preferably some research experience) in Aircraft Structures in the Department of Civil Engineering—The Registrar, The University, Leeds 2 (June 20).

Lecturer in Chemistry, and a Junior Lecturer in Biochemistry—The Secretary, Medical College of St. Bartholomew's Hospital, West Smithfield, London, E.C.1 (June 22).

Research Assistant in the Department of Botany, for research on physiological genetics using tissue culture techniques—The Secretary, University College, Gower Street, London, W.C.1 (June 22).

Research Assistant (with a good honours degree, a knowledge of French and German and the ability to draw maps) in the Department of Geography—The Registrar, The University, Leeds 2 (June 22).

Junior Fellow (with a university degree) in the Department of Veterinary Surgery—The Registrar, The University, Bristol 8 (June 26).

Assistant in Mathematics—The Secretary of University Court, The University, Glasgow (June 27).

Lecturer or Assistant Lecturer in Applied Mathematics—The Registrar, The University, Hull (June 27).

Lecturer or Assistant Lecturer (with special interests in organic chemistry) in Chemistry—The Registrar, The University, Sheffield (June 27).

Lecturer (with a medical qualification) in Bacteriology at the Royal Infirmary, Glasgow—Joint Clerk to the University Court, The University, Glasgow (June 27).

Research Fellow in Mathematics—The Secretary of University Court, The University, Glasgow (June 27).

Chair of Education in the University of Malaya—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (June 30).

Demonstrator in the Department of Organic Chemistry—The Registrar, The University, Leeds 2 (June 30).

Lecturer in the Department of Clinical Tropical Medicine—The Dean, London School of Hygiene and Tropical Medicine (University of London), Keppel Street, Gower Street, London, W.C.1 (June 30).

Lecturer or Assistant Lecturer in Organic Chemistry—The Registrar, The University, Leeds 2 (June 30).

Research Worker (with either an ordinary B.Sc. in chemistry and some knowledge of extraction and degradation of complex organic compounds or an honours B.Sc. with emphasis on natural products) in the Departments of Organic Chemistry and Botany, to aid an investigation into organic constituents of soils—The Registrar, The University, Liverpool (June 30).

Lecturer in Biochemistry at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, July 31).

Senior Lecturer (preferably with a sound knowledge of descriptive and/or experimental vertebrate embryology) in Zoology—The Registrar, University of Stellenbosch, South Africa (July 31).

Assistant Lecturer (with special qualifications in applied mathematics) in Mathematics—The Registrar (Room 22, O.R.B.), The University, Reading.

Assistant Librarian (Chartered Librarian, preferably with a working knowledge of German)—The Establishments Officer, Zoological Society of London, Regent's Park, London, N.W.1.

Fisheries Officer (with a university degree in biology with emphasis on zoology and experience of fisheries work) in the Northern Region of Nigeria, to execute plans for the development of river fisheries and the demonstration and organization of peasant fish culture—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.65/408/01.

Instructor or Assistant Professor in Protozoology—Dr. James R. Adams, Department of Zoology, University of British Columbia, Vancouver, B.C., Canada.

Junior Research Fellow in Mathematical Statistics—The Registrar, The University, Leicester.

Lecturer (with a good background in physics or chemistry with experience of research, as supervision of student thesis work is involved) in Plastics, and non-metallic materials generally, in the Department of Aircraft Materials—The Recorder, The College of Aeronautics, Cranfield, Bletchley, Bucks.

Master to teach Mathematics at all stages of the School, including the Sixth Form—The Headmaster, Boston Grammar School, Boston, Lincs.

Master to teach Physics up to at least first-year sixth standard—The Headmaster, King's College School, Wimbledon, London, S.W.19.

Professor of Physics at the University College, Colombo—The Ministry of Labour and National Service (E.9), 26–28 King Street, London, S.W.1, quoting E.9/72/TCS/CEY.

Reader in the Department of Electrical Engineering—The Registrar, Royal Technical College, Salford 5.

Research Biochemist (Ph.D. or Ph.D. candidate), for work on pyrimidine metabolism—Dr. Arnold H. Schein, Department of Biochemistry, University of Vermont College of Medicine, Burlington, Vermont, U.S.A.

Senior Lecturer (with a good honours degree in zoology and preferably a special interest in either entomology or physiology) in Zoology—The Secretary, Sir John Cass College, Jewry Street, London, E.C.3.

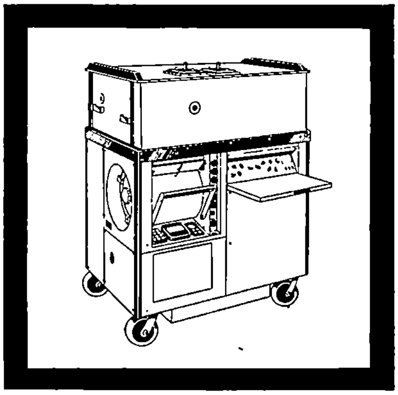
"The Infrared Spectrum..............."



" The infrared spectrum of a chemical compound is probably the most characteristic physical property of that compound."* From this fact has grown to-day's dependence on infrared analysis for rapid, complete information on the structure and composition of nearly all chemical compounds.

A parallel development in infrared instrumentation has reached its peak in the Unicam SP.100 Infrared Spectrometer which offers a unique combination of performance and utility. Both technical and commercial management in many fields have been quick to recognise a powerful tool in the search for a better product—or a better way of making existing ones.

Write for a detailed description of the SP.100 Spectrometer and for a copy of a new leaflet "Economics of Infrared" which indicates some of the ways infrared spectroscopy can help a lively business keep ahead.

* *G. B. B. M. Sutherland and H. W. Thompson, Faraday Society Transaction,* 41 *175 1945.*

TEACHING IN THE UNIVERSITIES

THE main functions of a university can be simply set down. There is the need to discover and interpret new knowledge; to impart knowledge and its interpretation to students; and to inspire them so that they will wish to join in the search for new truths themselves. In all that is done, the importance of imparting knowledge and understanding is pre-eminent. It is often wise to reflect how far this is successfully accomplished.

The university teacher has many critics; but those who are bad and beyond redemption are not nearly so many as the critics would have us believe. They are probably equal in number to those men and women who are naturally good lecturers and seem to have been born for the job. The large majority of university teachers are reasonably good craftsmen, sometimes aware of their deficiencies, conscious that their lectures frequently fail to impress, and whose shortcomings could be put right if they were prepared to spend some time learning their craft. They would get considerable help if they followed some of the advice put forward by G. Kitson Clark, reader in constitutional history in the University of Cambridge, and Commander E. Bidder Clark, who has had considerable experience with the use of visual aids to teaching in civil defence classes*.

As universities get bigger the problem of providing adequate and competent teaching staffs will become more and more acute. With increase in scientific and technological knowledge, the need for skilful exposition to promote real understanding will become more difficult, will require staffs prepared to make themselves good lecturers and who are prepared to use all the aids available to make their subjects intelligible.

The situation confronting a university lecturer is that confronting all lecturers. He must watch his audience to see that they are hearing and understanding him and that he is going neither too fast nor too slow. Yet how many lecturers find their inspiration on the ceiling, on the floor, or by the light of the windows: the students need not be present.

Nor should the lecturer be content with transmitting what is in his notes to the notebook of the student who, be he diligent, later returns them to the lecturer at an examination. The lecturer should seek to transmit what is in his mind to the mind of the student. This he will not do unless he periodically introduces checks to ascertain what is happening to the student's mind. A little acquaintance with the principles of pedagogy would help him considerably in practice.

For convenience, methods of instruction can be grouped into three. There is the straight lecture in which one voice alone is heard and which is particularly suitable for large classes. There is the discussion method in which a leader seeks to draw out and synthesize the combined knowledge and wisdom of a group. Then there is the 'lesson' method, so well developed in our schools, in which, by question and answer, the teacher uses an analytical method to develop knowledge and understanding in his pupil's mind. The tutorial class, so long an established feature at some universities, makes use of all three methods of instruction. The introduction of some questions and discussion would greatly improve the quality of many 'lectures', especially in science and technology, where the lecturer's voice is often broken only by the scratching of pens on paper.

Before a lecture begins, the teacher should consider his aims. As Kitson Clark and Bidder Clark write: he is there to serve his audience and should think of himself the whole time as "teaching *them*, interesting *them*, and giving *them* what they require, and can take". There is a limit to what men and women can digest in an hour, and too much produced too quickly in too complicated a fashion will leave them mystified and unsatisfied. The lecturer should aim at getting home a limited number of points, well defined, properly emphasized and arranged in some sort of logical order rather than in providing a running commentary or long stretches of narrative from which nothing stands out. Too often lecturers preparing their first course greatly exaggerate the amount that they will be able to cover in an hour as well as the amount of detail that they can deal with.

In general, the larger the class the slower the lecturer should go. The good lecturer, however, adapts himself to conditions which reveal themselves in the class-room itself.

The advice given by Kitson Clark is severely practical and contains hints as to how the lecturer should deliver his lecture. He suggests that the lecture should be divided into sections so that the lecturer may keep an eye on the clock and, if a section is taking up too much time, reduce it or cut it out altogether. The lecturer should take the class into his confidence and they should be told how he intends to arrange the course. A class which does not know where a particular lecture fits into a course will soon lose interest; and if, as some do, the lecturer conveys the impression that the course is not very important and rather uninteresting, he may not only lose the attention of the class but also their persons as well.

Many people find it a strain to listen too long to a lecture presented wholly in abstract terms. A lecture should be relieved from time to time by something concrete, a story used as illustration, a piece of narrative, or a striking fact which clinches some argument and makes it memorable; illustrations should be subordinated to the general purpose of the lecture.

---

* The Art of Lecturing: Some Practical Suggestions. By Dr. G. Kitson Clark and Commander E. Bidder Clark, O.B.E. Enlarged edition. Pp. 41. (Cambridge: W. Heffer and Sons, Ltd., 1959.) 3*s*. 6*d*. net.

The successful lecturer never under-rates his hearers' knowledge or under-estimates their intelligence. He does not talk down to them—a matter of judgment and of sensitivity which grows from careful and continuous observation of their reactions during the course of a lecture. Above all, and this is probably the greatest fault with the majority of bad lecturers, he does not give the class at any time information which is readily obtainable from standard text-books. It is a sad commentary on university teaching that many students leave having read little more than the notes provided by their lecturers; the use of books as guides and friends is something they have to acquire much later.

The lecturer should consider his own physical position when he lectures. He should look at the class the whole time, and will be more effective if he stands rather than sits. If he stands he should always check his mileage; some lecturers travel surprising distances in an hour. (One famous 'walker' was estimated to have covered five miles during a striking lecture on the ketones.) Too much restlessness, manipulative tricks with one's gown, balancing on the edge of the rostrum, are disturbing and fidgeting to a class; the mouth should remain visible.

Some of Kitson Clark's most useful advice concerns voice production. Speaking at a wall from about 5 ft. off and cupping one's ears with one's hands gives a good idea of the effect on an audience. A lecturer should speak up with his head well up; shouting is less easy to hear than a comparatively soft voice with the words properly enunciated. A higher pitched voice is more easy to hear, but a lower pitched voice is more agreeable to listen to. As a lecturer becomes preoccupied or fatigued the voice tends to work up to a high note, sounding unpleasant and strained. This is more common in women than men; sometimes they inadvertently "sound aggrieved or lachrymose because their voices have got out of control".

It goes without saying that no lecture will be successfully presented unless it has been thoroughly prepared; one wit has argued that all good lectures are given the night before. Other matters which the lecturer should consider are the use to which he will put his notes, whether or not he expects his class to take notes, and the form they will take, and positive recommendations about books.

The case for the use of visual or aural aids to learning needs no arguing. Yet it is still surprising how little or badly they are used. The blackboard is a much-abused instrument which is seldom used to full advantage. Previous preparation of maps or diagrams in invisible (purple) chalk is of great help to the lecturer unskilled in cartography; a chalk broken before use saves many nerve-rending squeaks, especially if it is held at an angle of 45° to the board. Bidder Clark describes the contributions to better learning made by the blanket board, the prepared 'chart', models, the episcope and the film projector. These are well known but frequently little used because of the extra trouble involved in preparation and in manipulation during the lecture. The lecturer who is most concerned with teaching his class will undertake the additional preparation required and will always be welcomed by his class.

The fact that some university lecturers approach their teaching with the dilettante air of the amateur bewilders many students who have been brought up to expect high standards and find the change from school to university somewhat disturbing. They ask themselves why this should be so in institutions which are adorned by institutes and departments of education. Are university teachers unable to profit from courses on pedagogy? This is a matter which should be carefully considered by vice-chancellors and principals, particularly in the light of the Willis Jackson Report on the Supply and Training of Technical Teachers. The position could well arise that, in future, students taking Diploma in Technology courses at senior technical institutions may be better taught and acquire greater depth of understanding of their subjects than students taught by the all-too-prevalent lecturing method so widely used in British universities.

MAN AND THE UNIVERSE

The Individual and the Universe

By Prof. A. C. B. Lovell. (B.B.C. Reith Lectures, 1958.) Pp. vii+111. (London: Oxford University Press, 1959.) 10*s*. 6*d*. net.

ONLY those who have actually been confronted with the task of giving a series of broadcast lectures on such a subject as "The Universe" can fully appreciate the difficulty of the assignment: the Reith Lectures particularly so, for with these it is expected that the speaker will go beyond the mere science and say something about the social, political, and even religious implications of his subject. Moreover he is cut off from any easy reliance on the developed language of science, faced as he is by an audience spanning the whole population and ranging from mentally unskilled everymen to hypercritical scientists who tend to frown on such excursions by their colleagues into the popular realm. These latter may be right from some points of view, and it may well be useless pandering to the curiosity of the man in the street by telling him at his own level about the latest developments in science, but as with most lecturing it is the lecturer that profits most, and I imagine that Prof. Lovell will agree that such a public performance can be a thrilling and salutary exercise.

I have to confess that it is beyond my comprehension why it should be that the problem of the expansion of the universe should be singled out above other problems of science to become strongly associated not only in the popular mind but also in that of philosophers and even scientists with religious and ethical matters. Although the interior of the Earth is a good deal less accessible to direct observation than are the remoter parts of the universe, yet people would laugh if some well-meaning geophysicist were to lecture on "The Individual and the Inside of the Earth". But the Reith lecturer must deal with his audience as he finds it, and Prof. Lovell is to be congratulated on this masterly presentation of a fascinating account of the epic struggles that scientists are now making to understand this mysterious universe. As effective owner of the world's largest telescope, Prof. Lovell naturally tends to lay emphasis on the importance of fabulously expensive equipment for solving these major problems, but unless strongly supported at every stage by theory, and the intelligent imagination needed to develop it, the meaning of the messages produced by such equipment will not always emerge. The encouragement of originality of thought, with the conflicts this involves, is perhaps the main social problem of science in our time or any other time so far, as Prof. Lovell is at pains to bring out in his talks.

The theories so far developed to account for the expansion of the universe, described herein, illustrate how easily theory can slip over into metaphysics. The 'big-bang' exploding super-atom hypothesis, with its attempt to 'explain' the expansion by postulating far less known things, seems to me reminiscent of Huygens' rarefied medium moving round the Earth with great velocity, introduced to 'explain' gravitation, when what is always wanted is a workable theoretical structure that can enable predictions to be made. My own feeling is that there is some major element still missing in our appreciation of this whole problem, and I would venture to predict that until some new theoretical approach on less mystical lines than hitherto is forthcoming, no serious progress with the problem will occur however large a telescope we or others build—mainly it seems at present, according to Prof. Lovell, to impress the neighbours. Nature seldom yields her secrets to this sort of wooing, but prefers the subtler approach.

I believe that the continued creation and maintenance of the universe will eventually seem as natural and intelligible by means of theory (yet to be established) as the view that the Earth is round seems natural and intelligible on gravitational theory, and that in such an attitude lies the only hope of solving this or indeed any other problem. Even though at present it seeems difficult compared with problems already solved, there are not the smallest grounds for suspecting that its solution is destined to remain for ever beyond the range of man's intelligence and inventiveness. And this spirit of hopefulness for scientific method is the main message that pervades Prof. Lovell's enthralling lectures.

R. A. Lyttleton

CAMBRIDGE ANTHROPOLOGY

The Developmental Cycle in Domestic Groups

Edited by Dr. Jack Goody. (Cambridge Papers in Social Anthropology, No. 1.) Pp. vii + 145. (Cambridge: At the University Press, 1958. Published for the Department of Archæology and Anthropology.) 21*s*. net.

THIS is the first in a projected series of symposia in social anthropology, each to be devoted to essays by Cambridge anthropologists on a particular theoretical topic. The theme of this issue is the changing form and significance of the domestic group during its development, and the analytical use of taking this process into account.

The volume comprises an introduction by Prof. Fortes and four papers, three of which are based on field research by their authors. Freeman, in a characteristically thorough ethnographic description, deals with the formation and partition of the family among the Iban of Borneo: his essay is of especial value in that they reckon descent cognatically, a widespread mode of relationship the theoretical interest of which has been obscured by an almost exclusive concern of anthropologists with lineal descent systems. Goody correlates differences in social groupings and processes of production with variant rules of inheritance in West Africa. Stenning relates the composition and stability of the pastoral Fulani domestic group to the herd on which it depends, and incidentally gives some information on a highly interesting dyadic system of symbolic classification. The concluding essay, not based on field research but an analysis of Trobriand data, is a brilliant demolition by Leach of Malinowski's assumption that the different and apparently conflicting meanings of the word *tabu* are unrelated homonyms. This theoretical exercise is related to the volume's theme mainly in its consideration of the significance of the change of a Trobriand youth's residence from his father's to his mother's brother's hamlet; but it is of far wider theoretical import than this theme, for Leach deals also with origin myths, incest and exogamy, political hierarchy, local groupings, land-holding, economic obligations, and why the Trobrianders happen to have four clans. It is a little chastening to reflect that such ingenuity as Leach displays is required to give systematic conviction to Malinowski's renowned data and to order the facts of Trobriand life as the people themselves do. This fascinating structural analysis shows how necessary and profitable it is to take native categories seriously, and how essential it is to understand the social structure if we are to grasp what the terms denoting these categories mean. The essay bears the marks of a sociological classic, and alone would justify the launching of a new publication. Its author is to edit and introduce the second number in the series—on caste—and one eagerly awaits this as any vehicle for the ideas of one of the most fertile and penetrating minds in social anthropology.

Rodney Needham

EXPERIMENTAL STUDIES OF PERCEPTION

Readings in Perception

Selected and Edited by Prof. David C. Beardslee and Prof. Michael Wertheimer. (The University Series in Psychology.) Pp. xiii + 751. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: D. Van Nostrand Company, Ltd., 1958.) 66*s*.

THIS book is a valuable attempt to represent the present position in the experimental psychology of perception, and to some extent also the steps which have led up to that position, by means of outstanding papers and chapters from important books. The result is an extremely interesting and often rather bewildering collection of fifty-two selections grouped under five main headings.

The authors consider that they have selected studies which represent the core of the experimental psychology of perception, upon which so much current research in the fields of personality, motivation and social psychology is built. They have included a large number of recent investigations, which show the reader clearly what has been and is being done in the study of perception, and will certainly give him a vivid impression of the tremendous interest, complexity and difficulty of the tasks of research. Some of the papers are models of clear thinking, lucid exposition and decisive conclusions. The instructive quality of others lies partly in the evident difficulty of satisfactorily controlling the experimental conditions, and/or drawing conclusions upon which confidence may be placed. Some papers are models of nearly unreadable prose, but in a collection in which the level of specialization of the contributions is unavoidably so varied, this may be inevitable. The editors have also wisely included some papers of classical interest, provided they have not been rendered obsolete by more recent research. These are landmarks for the reader. It is illuminating that in passing from the work of men of outstanding genius to that of ordinary experimenters there is often such a vivid impression of the differences between them. The problem of classification of the papers chosen seems to have been a very difficult one, and anybody reading the book or taking parts of it for discussions, lectures or seminars, would probably have to re-arrange the papers in an order which he felt to give a rational sequence.

The main themes covered by the book are: (1) biological factors in perception (two papers); (2) psychophysical measurement (one paper); (3) perception of objects and events, divided into five sections, (*a*) the stimulus field and its differentiation (four papers), (*b*) perception of organized figures and areas (twelve papers), (*c*) effects of learning and limited experience (four papers), (*d*) perception of successive and changing stimuli (seven papers), (*e*) space perception (eleven papers); (4) imagery and fantasy (three papers); (5) recognition and identification of figures, divided into two sections, (*a*) perception of words as stimuli (five papers) and (*b*) perceptual categorizing (three papers).

In reading the book it is interesting to consider whether the editors might not have done better to re-write the whole mass of material in their own words. At least the length of many papers could have been greatly reduced with advantage. Much boring matter could have been eliminated, and the essential points could have been brought into clear focus. However, in doing this, they might have lost the unique quality which belongs to the thought and writing of many of the gifted authors represented in the collection.

R. W. PICKFORD

EARLY STEAMBOATS

The Birth of the Steamboat

By H. Philip Spratt. Pp. 149 + 11 plates. (London: Charles Griffin and Co., Ltd., 1958.) 28*s*. net.

THIS authoritative little book has clearly been a labour of love on the part of the author and it will be of interest mainly to the specialist rather than to a general reader.

The subject-matter is grouped under the three main headings of "Inventive Aspirations", "Experimental Steamboats" and "Steamboats in Service", and each chapter then deals in chronological order with the various inventors, experimenters or builders who had any effective impact on steamboat development. The book thus tends to be rather episodic, but the author attempts to overcome this by inserting cross-references in the text where necessary. There is a good index, and the list of references is impressive: 390 of them from libraries in Great Britain, the United States, France, Canada, Italy, Germany and Spain.

The material is given factually and without bias. The great names stand out and one cannot help but feel disappointment that the great French pioneer, the Marquis Claude de Jouffroy d'Abbans, was not successful with his fine vessel, *Charles-Philippe*; the ratchet mechanism that he used to drive the paddles proved defective. One of the most likely early vessels was one built by the partners, Fourness and Ashworth, of Yorkshire, having three steam cylinders acting on a three-throw crankshaft driving two paddle wheels. It is described as having undergone "severe tests on behalf of the Prince Regent". Unfortunately, the vessel was soon afterwards mischievously burnt before it had any chance of extended service.

The book clearly brings out the reasons for the failure or success of most of the vessels tried and, as well, it emphasizes that the success attained by that great American steamboat pioneer, Robert Fulton, was considerably due to his willingness to make himself familiar with the work of others in the use of steam and adapt their ideas to his own use. He made no claim to invention but concentrated his attention on well-tried mechanisms and tested hull proportions.

The book closes at 1822 with the development of the first iron-built steamer to put to sea, *Aaron Manby*, and the author has completed a volume which gives the background of the endeavour and the efforts, the triumphs and the failures of those pioneers who made modern ocean commerce possible.

In talking of the size of machinery, reference is often made to a figure for 'nominal horse-power'. It would have added to completeness if a definition of this term had been included.

A. W. JONES

MODERN TAUBERIAN ANALYSIS

Tauberian Theorems

By Prof. H. R. Pitt. (Tata Institute of Fundamental Research Monographs on Mathematics and Physics, No. 2.) Pp. x + 174. (London: Oxford University Press, 1958.) 37*s*. 6*d*. net.

THE integral transform:

$$f(x)=\int k(x,y)\,g(y)\,\mathrm{d}y$$

where k is a given kernel, defines f, in a sense, as an average of g; hence we might expect that while properties of f will follow the type of properties of g, the converse inference will not usually be possible without supplementary conditions. Thus Abel's theorem, that if Σa_n is convergent, lim $\Sigma a_n x^n$ exists as $x\to 1$, has a false converse, which becomes true if supplementary conditions are laid on the a's. Tauber (1897) gave the condition $na_n \to 0$, but this, though sufficient, is not necessary.

The first phase of Tauberian theory began in 1910, when in spite of formidable difficulties, Littlewood showed that a sufficient condition for the Abel converse is that na_n should be bounded; the distinction between tending to zero and being bounded marks a general and characteristic difference between the 'elementary' and the 'deep' theorems in this field. The Hardy–Littlewood partnership then obtained and exploited numerous Tauberian theorems. The second phase dates from about 1923, when Wiener showed that practically all the known Tauberian theorems could be expressed in terms of integral transforms with kernels of the type $k(x-y)$, thus shifting emphasis from results about summation processes for divergent series to a more general theory of transforms. Since then the theory has branched out in several directions, and a comprehensive treatise would be voluminous. But along the main lines laid down by Hardy–Littlewood and Wiener, simplifications and generalizations have been made by many workers, among whom Prof. Pitt has been prominent.

He has now organized this material into a single short volume, the second in the series of monographs on advanced topics sponsored by the Tata Research Institute of Bombay. It is a book for the professional mathematician contemplating work in this field, and a fair degree of sophistication is needed to follow the clear but very concise reasoning. There are chapters on the Hardy–Littlewood and Wiener theorems, and one on theorems developed from Mercer's result (1907), that if σ_n is the mean of $s_1, \ldots, s_n$, and $\alpha > 0$, the convergence of $\alpha s_n + (1-\alpha)\sigma_n$ implies the convergence of s_n; this has the remarkable air of being a Tauberian theorem without a Tauberian condition. Finally, there is a chapter on the prime number theorem; here it appears essential to work with means related to the primes, so that Tauberian theorems are obviously relevant. But Pitt points out that neither the Ikehara-Landau proof, perhaps the simplest, nor the recent Selberg-Erdös proof, certainly the most elementary since it demands no knowledge of Riemann's ζ-function, uses Wiener-type Tauberian theorems, and he offers some pointers towards a study of general Tauberian theorems which are not of Wiener's type. If this prompts some young research worker to investigate the topic, the author and the Tata Institute should be gratified. T. A. A. Broadbent

MAGNETIC AMPLIFIERS

The Theory and Design of Magnetic Amplifiers

By Dr. E. H. Frost-Smith. (Automation and Control Engineering Series.) Pp. xix + 487. (London: Chapman and Hall, Ltd., 1958.) 75*s.* net.

THIS well-written and comprehensive book can be recommended to both students and professional engineers, and many will wish that it had appeared earlier.

The introductory chapter is noteworthy for the emphasis which it puts on mean rectified values of voltages and currents in terms of which transductor characteristics are conveniently described. Two chapters are then devoted to the principal parameters and characteristics, both steady-state and transient, of transductors with idealized core-materials. From this basis the theory of self-excited and auto-excited transductors with practical core-materials and imperfect rectifiers is developed and the influence of reactive loads is discussed.

A short chapter on the theory of control systems is included and a further treatment of the dynamic response of transductors with resistive and reactive loads is discussed in terms of control-system theory. This leads naturally to the need for quick-response transductors in control systems and an admirable chapter is devoted to half-wave, full-wave and three-phase transductors having short-response times.

The three chapters which follow deal with balanced magnetic amplifiers, low-level signal amplification and cascaded amplifiers, and magnetic modulators.

The section on design summarizes the properties of core-materials and their influence on transductor characteristics. A design procedure is developed and is illustrated by three examples, one of which extends to the overall performance of a magnetic-amplifier position-servo. The mixture of units with which engineers still have to deal, despite the adoption of the M.K.S. system for basic equations, is apparent in this chapter.

The final chapter on applications covers a wide field and leaves no doubt as to utility of transductors.

Most chapters have concluding summaries and these, together with the list of references to original papers, make this book a valuable acquisition for engineers entering this field. J. G. Henderson

TREES OF BRITAIN

Trees of Britain

By Dr. Robert Gurney. Pp. 228 + 18 plates. (London: Faber and Faber, Ltd., 1958.) 30*s.* net.

THE late Dr. Robert Gurney had wide biological interests and collected a great deal of information from his own painstaking observations over a period of many years, particularly around Oxford (his home) and in Norfolk. Trees were, perhaps, his primary interest in his later years, and an earlier book of his, "Our Trees and Woodlands" (Medici Society, 1947), will be known to many. The present volume possesses certain special features that are not to be found in the usual books dealing with trees in the British Isles. Most of the books that have appeared hitherto have dealt either with the native trees or with the introduced trees, grown for ornament or for timber. In the present volume Dr. Gurney deals with both these categories, covering all the common trees, wild or cultivated, that are to be found throughout the country. About one hundred different species are dealt with, each receiving separate treatment. The general information accompanying each description includes facts concerning the origin of each species, date of introduction to Britain (where known), general behaviour and growth characteristics. The clear line drawings that accompany each description are a notable feature of the book. They are the work of Dr. Gurney himself, and they usually include a drawing of the seedling, which the author raised from seed which he had himself collected. Another feature of the book is the emphasis that has been placed on buds or bud morphology, and bud development, the features brought to light being illustrated in the drawings. In addition to line drawings there are photographs showing individual trees or groups of trees in various parts of the British Isles. These are all pleasing or exceptional photographs of their kind and may well have been selected for their æsthetic value.

In the section on "Conifers and their Allies", all the species yielding softwoods of importance in Britain or of use in other respects are described. A table giving the dates of introduction of coniferous trees to Britain is of interest. From this it appears European spruce (*Picea abies*) is the earliest introduction (1548), while *Metasequoia glyplostroboides* is the most recent (1948). It is of interest to note that two important conifers, Japanese larch (*Larix leptolepis*: introduced 1861) and western hemlock (*Tsuga heterophylla*: introduced 1863), have not yet been in cultivation for a hundred years in the British Isles.

F. N. Howes

How to Know Western Australian Wildflowers

By William E. Blackall and Dr. Brian J. Grieve. Part 2: A Key to the Flora of the Temperate Regions of Western Australia. Pp. xxxiii + 321–460 + lvii. (Nedlands, W. A.: University of Western Australia Press, 1956.) 30*s*.

SINCE Gaston Bonnier and G. de Layens—with their classic "Flore de la France", published so long ago as 1887—introduced the illustrated-key type of flora, there have been many imitations. The book noticed here is the first example dealing with any part of the flora of Australia and is, in the reviewer's opinion, a good example of this type of flora. Actually the present work is Part 2 of a book first published in 1954, this part containing families 60 to 72 of the original scheme and also the family Goodeniaceae which is of especial interest in Western Australia. Dr. Blackall's original manuscripts have again been worked up by Dr. Grieve and the whole checked against as much fresh and dried material as could be obtained. From examination of the keys forming the flora it is clear that the results of monographic or other specialist work have been fully incorporated.

On the whole the drawings accompanying the different alternatives presented in the keys illustrate well the characters mentioned in the text, though in some cases the small scale makes it difficult to show the special features as clearly as one would have liked. This, however, is a common defect in such illustrated floras. Small sketches of all the species keyed-out help the student to confirm the correctness of his determinations. A complete key to the families in the whole flora is included, while the index to the species gives the authorities for the names and also the distribution according to a standard map provided. There is also a useful glossary. In addition to the many drawings in the key itself, there are five coloured plates which illustrate some of the more striking plants included in this part. Altogether, Dr. Grieve is to be congratulated on the continuation of a useful book. V. S. Summerhayes

The Cherry Kearton Animal Book

By Cherry Kearton. Pp. 168 + 16 plates. (London: Hutchinson and Co. (Publishers), Ltd., 1958.) 12*s*. 6*d*. net.

SOME of the best stories and anecdotes of Cherry Kearton's pet animals have been incorporated into this entertaining volume. In it the reader will meet Simba, the intrepid fox terrier, whose adventures in Africa are a far cry from his acquisition by Cherry Kearton at the Battersea Dogs' Home, and Toto, the intelligent and mischievous chimpanzee who accompanied his owner on some of his African travels. Another section of the book illustrates the wide range of Cherry Kearton's interest in animal life and recounts his friendships with a penguin, an Algerian sand rat and a trapdoor spider. The book closes with some stories of Mary, in her time probably one of the best known chimpanzees in the world, whose accomplishments seem at times to be almost human.

Cherry Kearton's pleasant and easy style carries the reader effortlessly through these stories of his animal friends, and throughout them there runs his understanding that patience and kindness are the only ways to gain the trust and affection of animals. The book is illustrated with photographs of its characters, and in addition there are a few photographs of animals in their natural setting. There is little to criticize: deer do not occur in Africa and three of the photographs have little relation to the text. The book has an obvious appeal to children, and is an admirable introduction for them (and perhaps for their parents) to the writings of Cherry Kearton. J. E. Hill

Nuclear Reactor Metallurgy

By Walter D. Wilkinson and William F. Murphy. With a chapter by Warren J. McGonnagle. Pp. viii + 382. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: D. Van Nostrand Company, Ltd., 1958.) 42*s*.

THIS book is based on a course of lectures given at the Argonne National Laboratory since 1955. Appropriately, at least half of it deals with uranium, which is treated in detail from the ore to radiation damage in the reactor in a series of chapters. Other chapters deal with plutonium, thorium, ceramics, canning and control rod materials, liquid metals, and radiation damage in engineering materials. A final chapter on non-destructive testing is contributed by Warren J. McGonnagle. In general, the treatment of the chemical and metallurgical engineering topics is much better than that of the physical topics. The important effects of thermal and irradiation strains on the mechanical properties of uranium are overlooked, and the discussion of specific heats and thermal conductivity in Chapter 6 is very weak. Radiation damage in graphite is dismissed in four lines. This latter, as well as the omission of a discussion of magnesium as a canning material, is perhaps understandable since the authors confine themselves mainly to American reactors; but it will disappoint British readers. The chapter on liquid metals is interesting, as are also those on thorium, beryllium, and zirconium, and the book as a whole serves as a useful partial account of the science of reactor materials. A. H. Cottrell

Truth and Denotation

A Study in Semantical Theory. By Prof. R. M. Martin. Pp. xii + 304. (London: Routledge and Kegan Paul, Ltd., 1958.) 42*s*. net.

THIS is likely to be a useful book, both to the specialist and to anybody who is prepared to take some trouble to read and think carefully about formalized languages and their place in the methodology of science. It will go some way to answer the question as to why mathematicians and logicians invent the particular signs and symbols which are now becoming almost common coin. The first chapter deals in general with this theme, whereas the rest of the book is an able and clear discussion of the machinery, including such topics as first-order languages, syntax, non-translational semantics, and the theory of sets and types.

It is well to recollect that it is a feature of non-translational meta-languages that they are not strict translations of the object language. Thus is introduced the relation of 'comprehension'. The importance of this, among other things, is that the classical system of Aristotelean logic is not very satisfactory, when *relations* are involved; but from here, with one semantical primitive, one can build up a species of extended Boolean algebra. It will be interesting to see whether it will stand up to the desire of some applied mathematicians to use these methods for complex electrical networks. Considerable success has already attended efforts to do so with some of the 'classical' Boolean equations. F. I. G. Rawlins

THE ROCKEFELLER INSTITUTE, NEW YORK: A NEW GRADUATE UNIVERSITY

By L. J. F. BRIMBLE

History and Constitution

IN the United States, it was considered that up to 1900 the growth of medical science had not kept pace with the physical sciences, despite the constantly increasing rate at which medical research had been carried on in American universities. Therefore, Mr. John D. Rockefeller accepted the expressed opinion of his adviser, Frederick T. Gates, that "medicine could hardly hope to become a science until it should be endowed, and qualified men be enabled to give themselves to uninterrupted study and investigation, on ample salary, entirely independent of practice". As a result, the Rockefeller Institute for Medical Research was founded in New York during 1901 by Mr. Rockefeller "to conduct, assist and encourage investigations in the sciences and arts of hygiene, medicine and surgery, and allied subjects, in the nature and causes of disease and the methods of its prevention and treatment, and to make knowledge relating to these various subjects available for the protection of the health of the public and the improved treatment of disease and injury . . . to use by any means . . . including research, publication, education, and the establishment and maintenance of charitable and benevolent activities, agencies and institutions appropriate thereto . . .".

The original Board of Directors, comprising William H. Welch (president), T. Mitchell Prudden, L. Emmett Holt, Theobald Smith, Christian A. Herter, Herman M. Biggs and Simon Flexner first set out to study the availability of adequately trained younger men in universities for the furtherance of medical research. The first rented buildings, at 127 East 50th Street, were directed by Simon Flexner, and there investigations in pathology, bacteriology, physiology and biological chemistry were conducted, thus immediately establishing medicine as a science. Later, Mr. Rockefeller purchased the land overlooking East River in York Avenue at 66th Street which now forms the present campus of the Institute. There he had built a laboratory, now known as Founder's Hall (Fig. 1) which was completed in 1906, and this provided space for experimental surgery and experimental biology in addition to the subjects already mentioned.

In 1908, Mr. Rockefeller provided further funds for the establishment of a hospital and isolation pavilion (Fig. 2). This was opened in 1910 with Rufus Cole as director. To this day, only patients of special scientific and medical interest are admitted on the recommendation of a panel of medical men. There they receive exceptional treatment and excellent service and nursing. In return for this they may be looked upon as contributing their diseases for the benefit of medical learning, for no payment is allowed, whether they be rich or poor.

At the same time, a Corporation was set up with increased powers. It included a Board of Trustees as well as the original Board of Directors, the name of the latter having meanwhile been changed to Board of Scientific Directors. The first president of the new Corporation was Frederick T. Gates (adviser to Mr. Rockefeller), and on his death in 1929 he was succeeded by Mr. John D. Rockefeller, jun., who, after twenty-one years service, was followed by his son, Mr. David Rockefeller. As time passed, further generous gifts were made by Mr. John D. Rockefeller and his son (Mr. John D. Rockefeller, jun.).

In 1914, a Department of Animal Pathology was established for the Institute near Princeton University under the directorship of Theobald Smith, who was succeeded in 1930 by Carl TenBroek. In 1931, research in plant pathology was also introduced, so that now the Institute could rightly claim to cover all the main groups of living things. In 1951, the work of the laboratories of animal and plant pathology at Princeton was transferred to the campus in New York.

Simon Flexner retired from the directorship of the Institute in 1935, and he was followed by Herbert S. Gasser, who remained in charge until 1953, when he was succeeded by Thomas M. Rivers. Both Dr. Gasser and Dr. Rivers are now directors emeriti of the Institute, and both still have rooms there.

The year 1953 saw extensive re-organization of the Institute, and Dr. Detlev Wulf Bronk was appointed first president of the Rockefeller Institute of Medical Research. Dr. Bronk is also president of the U.S. National Academy of Sciences, chairman of the National Research Council, and one of America's leading physiologists. He has been professor of physiology in Cornell University and professor of biophysics and director of the Johnson Foundation, University of Pennsylvania. Eventually he became president of the Johns Hopkins University (1948–53) before transferring to the Rockefeller Institute. He is a foreign member of the Royal Society. It has not taken very long to prove that the Institute was indeed fortunate in the election of Dr. Bronk.

In 1953, the Boards of Trustees and of Scientific Directors were merged into a single Board of Trustees which now has fifteen members. They are laymen of distinction in public affairs and men of outstanding scientific achievement, in the ratio of about one to one. These include: Mr. David Rockefeller (chairman), Dr. Detlev Bronk, Prof. R. F. Loeb, Prof. G. H. Whipple, Prof. William J. Robbins, Prof. Philip Bard and Prof. Vincent du Vigneaud.

At present, the staff of the Institute includes twelve members emeriti, all of whom have earned international reputations for their researches in the life sciences; twenty-nine members and professors; seven affiliates; nineteen visiting professors, including such authorities as Lord Adrian of Cambridge (physiology), Prof. T. Dobzhansky of Columbia (zoology), Prof. L. Edelstein of Johns Hopkins (humanistic studies), Prof. Ragnar Granit of Stockholm (neurophysiology), Dr. L. J. Haworth, director of the Brookhaven National Laboratory, Prof. J. G. Kirkwood of Yale (chemistry), [the late] Prof. K. V. Linderstrøm-Lang, Carlsberg Laboratory, Copenhagen (chemistry), Prof. A. M. Monnier of the University of Paris at the Sorbonne (functional physiology), Prof. I. I. Rabi of Columbia (physics), Prof. William J. Robbins,

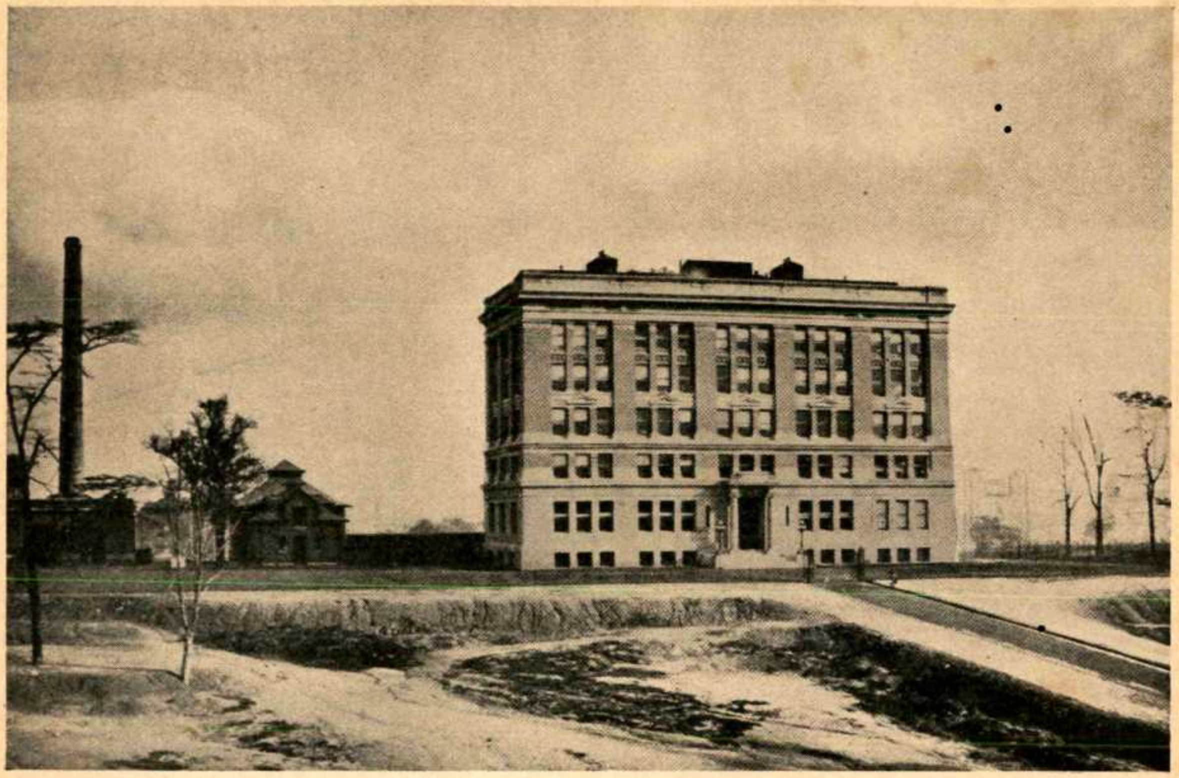

Fig. 1. The Rockefeller Institute for Medical Research as photographed in 1906. Founder's Hall, the only building then in existence

formerly of Columbia (botany), etc.; twenty-four associate professors; thirty-two assistant professors; sixty-two research associates; and forty guest investigators. Prof. Frank Brink is dean of graduate studies, and graduate fellows will this year number 65.

After about fifty years activity, and in order to include graduate education in the natural sciences with special emphasis on the life sciences, the charter of the Institute was amended in 1954 so that it could become part of the University of the State of New York with authority to grant the advanced degrees of doctor of philosophy, doctor of medical sciences, doctor of science (*honoris causa*) and doctor of laws (*honoris causa*). Thus the Institute assumed the status of a graduate university; there are, of course, no undergraduates. It cannot be said, therefore, that the Rockefeller Institute, as a university, is a one-sided affair, for all students have already had those educational and other benefits associated with a full university course before being admitted.

In 1954, the fiftieth anniversary of the opening of the first laboratory, three new buildings were opened, so that then there were Founder's Hall, Welch Hall, Simon Flexner Hall and Theobald Smith Hall, and the Hospital. Since that date, other buildings have been erected and are in use, whereas others are undergoing completion. These are an auditorium, a huge laboratory building, a faculty-visiting scientists social centre, a graduate residential hall, a building for seminars and conferences and a President's House. These buildings and the superb landscaping of the campus (Fig. 3) have been rendered possible by gifts from the estate of Alfred H. Caspary and from Mr. John D. Rockefeller, jun., Mr. David Rockefeller and the United States Public Health Service.

In 1958 the charter of the Institute was amended to change its name from that of Rockefeller Institute for Medical Research to the Rockefeller Institute—a wise decision in view of the comprehensive researches in the life sciences which are now being carried out there.

The current market value of the Institute's endowments is more than 160 million dollars. At present, no more than seventy-five students are to be admitted, at the rate of about twenty each year, to read for the degree of doctor of philosophy or doctor of medical science, so that here we have an aggregate body, a community of scientific scholars, living and working under ideal conditions—a place where they can work, think and dream, away from the sometimes excessive demands made by administration and teaching. The students are few, the faculty (staff) are many. Their creature comforts are catered for in an environment at once functional, beautiful and serene.

The entire organization is of a flexible and personal nature, built around individuals rather than departments, thus allowing the maximum freedom for research and study. The subjects at present being pursued are diverse: they include animal pathology, biochemical genetics, biochemistry, biophysics, biosynthesis, cytology, developmental biology, ecology, general physiology, genetics, history of science, immunology, mathematics, medicine, neurophysiology, parasitology, pathology, physical and organic chemistry, physiology of reproduction and plant pathology.

This academic institution must be unique. It is essential that the graduate students fortunate enough to be accepted be capable of self-directed study. Teaching is mainly done in seminars, tutorial conferences and in faculty research laboratories. The first three months of each initial academic year are devoted to lectures, seminars and discussions in many fields of natural science. Each week a topic in basic science is discussed by one or more members of the staff. Thus, at the outset of his career the student is enabled to develop a broad foundation of competence in many related fields of science and to grasp the connexions of his special field of research with other aspects of science. Thereafter, the educational programme is designed to suit the needs and interests of each individual student. As soon as the student has formulated a significant problem for investigation, he is encouraged to begin research either independently or under the direction of one or more members of the faculty, knowing full well that extraordinary physical facilities for research are at his disposal.

Moreover, in close proximity to the Institute are opportunities for satisfying interests in the theatre, art, literature, music and other branches of science, and fellowship stipends are of a magnitude to permit students to take some advantage of these (see, for example, *Nature* of May 16, p. 1365). Truly, an international centre of research and culture, for, as the supervisor of one of the Halls remarked: "These students and research workers are also men and women". They look not only inside but also outside the Institute for full development and—the main aim of education—complete living.

First Convocation

The first Convocation of the Rockefeller Institute as a graduate university was held during May 21–22. It opened with a luncheon attended by about three hundred guests, including members of the Rockefeller family, some other prominent Americans and distinguished scientific and academic guests.

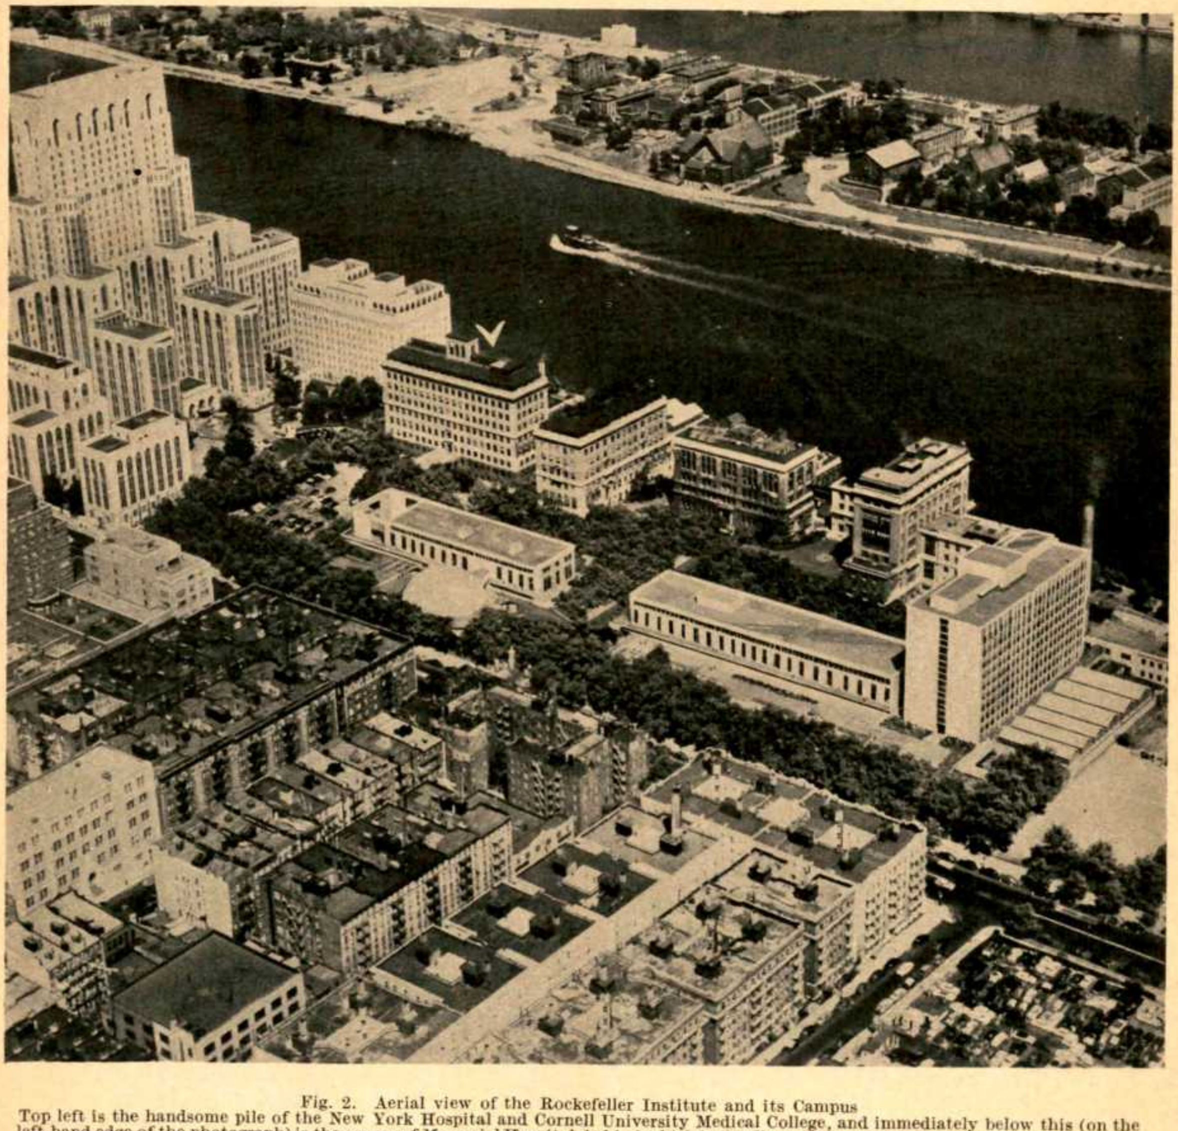

Fig. 2. Aerial view of the Rockefeller Institute and its Campus
Top left is the handsome pile of the New York Hospital and Cornell University Medical College, and immediately below this (on the left-hand edge of the photograph) is the corner of Memorial Hospital, behind which is the Sloan–Kettering Institute for Cancer Research. The arrow indicates Theobald Smith Hall of the Institute, behind which is the President's Residence—a beautiful home built in contemporary American style and commanding a magnificent view of East River. Passing to the right are: Flexner Hall; Founder's Hall (see Fig. 1); behind this on the lower slopes facing the River is Welch Hall; the Hospital. On the extreme right are the new laboratories which are nearing completion. Next to this, and facing York Avenue, is the Graduate Students' Residence Hall. Further to the left are Caspary Hall and Abby Aldrich Rockefeller Hall (both included in one building), in front of which is the dome-shaped Caspary Hall Auditorium

In the afternoon, four commemoration addresses (to be published in later issues of *Nature*) were delivered by: Dr. Detlev Bronk, president of the Institute and of the U.S. National Academy of Sciences; Dr. Douglas M. Knight, president of Lawrence College, one of America's leading undergraduate colleges; Lord Adrian, Master of Trinity College and vice-chancellor of the University of Cambridge; and Dr. Henry A. Moe, secretary-general of the John Simon Guggenheim Memorial Foundation and president of the American Philosophical Society.

A reception and dinner were held in the evening, followed by a concert in the auditorium of Caspary Hall. This concert was given by a section of the New York Philharmonic Orchestra conducted by Carlos Surinach. Apart from one item, the pieces played were by contemporary composers—all American except for one Japanese and one Mexican. Introductory remarks by the conductor and the presence of some of the composers rendered this musical occasion one to be happily remembered, for the presentation was exquisite. Even he without an ear for music or he who usually cannot understand or appreciate the modern musical idiom could not help but be impressed by such a full-blooded and enthusiastic performance.

Dancing followed inside and outside the Abby Aldrich Rockefeller Hall under a full moon.

The proceedings on the following day were initiated by the first graduation of this new university—a completely honorary graduation, for the first so-called 'earned' graduation was to be held a few weeks later. The degree of doctor of laws (*honoris causa*) was conferred on the highest academic officers of six of the oldest universities in Europe and the Americas and on Mr. John D. Rockefeller, jun. With the exception of the last-named, the recipients were presented in order of age of the institution they represented.

Dr. G. G. Forni, rector of the University of Bologna, was presented by Prof. R. Dubos, professor of pathology and microbiology in the Institute. Bologna is the oldest of Europe's universities: by tradition it was founded in 1088, though the names of some teachers in Bologna have survived in parchments dating from 1067. By the year 1200, Bologna had some 10,000 students, most of them from foreign lands. Throughout the centuries, this University has been able to count among its alumni such great names as Dante, Petrarch, Copernicus, Malpighi, Margagni, Spallanzani, Galvani and Marconi.

Dr. T. S. R. Boase, president of Magdalen College and vice-chancellor of the University of Oxford, was presented by Prof. G. W. Corner, historian of the Institute. Oxford is the oldest university of the English-speaking world, dating from the reign of Henry II, when, in 1167, foreign-born scholars were driven from Paris. As pointed out by Prof. Corner: "in the year 1649, three hundred and ten years ago, a handful of scholars, vanguard of the new era in experimental science, founded the Philosophical Club, cradle of the Royal Society, exemplar of our National Academy of Sciences". Oxford has been called the 'home of lost causes'; but this is only another way of saying that she is for ever the home of a cause our world must never lose—the cause of liberty to study, think and teach with untrammelled mind in the free city of the spirit.

Lord Adrian, Master of Trinity College and vice-chancellor of the University of Cambridge, was presented by Prof. Peyton Rous, professor emeritus of pathology and microbiology in the Institute. Cambridge also dates back to the twelfth century, and was granted its charter during the reign of Elizabeth I. Oxford and Cambridge "have gone forward side by side throughout almost seven hundred years and have been competitors along most of the way, however impersonal their scholars. Together they emerged from Scholasticism, changed with the Reformation, weathered the Puritan Revolution, the Georgian Era; and yet despite all vicissitudes neither has gained superiority over the other when viewed in the sharp light of the present. Where else does such a state of affairs obtain amongst old universities? Can it be that the love of the English people for contests under fair terms has extended far beyond boat races that almost subconsciously, by giving and taking in a myriad ways, they have maintained the great rival universities in balanced power?"

Dr. J. L. Barandiaran, rector of the University of San Marcos, Lima, Peru, was presented by Prof. R. E. Shope, professor of animal pathology in the Institute. The University of San Marcos was founded in 1551 by royal decree issued by Charles V of Spain. Since that time, it has developed a distinguished record as a centre of intellectual leadership.

Dr. Nabor Carrillo, president of the National University of Mexico, was presented by Prof. Paul A. Weiss, professor of developmental biology in the Institute. This University was also founded in 1551 by Charles V of Spain. It now has a large number of students and teachers working on what must be one of the most beautiful and impressive campuses in the world.

Dr. N. M. Pusey, president of Harvard University, was presented by Prof. A. E. Mirsky, professor of general physiology in the Institute. Harvard, the oldest college in the United States, was founded in 1636 with a gift of £400 from the General Court of the Massachusetts Bay Colony. In the same year, John Harvard, of Emmanuel College, Cambridge, and a Puritan immigrant, bequeathed to the seminary £780 and 260 books; the College was then re-organized, and in 1639 was named Harvard College. Such alumni as Lowell, Longfellow, Agassiz and Emerson have left their stamp on that University; and such presidents as C. W. Eliot, A. L. Lowell and J. B. Conant influenced the entire course of American education.

Owing to his indisposition, the degree of doctor of laws (*honoris causa*) was conferred on Mr. John D. Rockefeller *in absentia*. His son, Mr. David Rockefeller, received the insignia of the degree, after a moving citation by Dr. Detlev Bronk. John D. Rockefeller was born on January 29, 1874, and in 1901 he married Miss Abby Greene Aldrich. They had one daughter and five sons—John D. 3rd, Nelson A. (now governor of New York), Laurance S., Winthrop and David (chairman of the Board of Trustees of the Institute). His life has been devoted to the philanthropic and civic activities of the Rockefeller family, particularly those designed to advance human welfare and those furthering international, inter-faith and inter-racial concepts. He has been active in the organization, administration and policy development of these activities and has made many of them financially possible. He was associated with his father in the creation and development of the Rockefeller Institute for Medical Research in 1901, the General Education Board in 1902, the

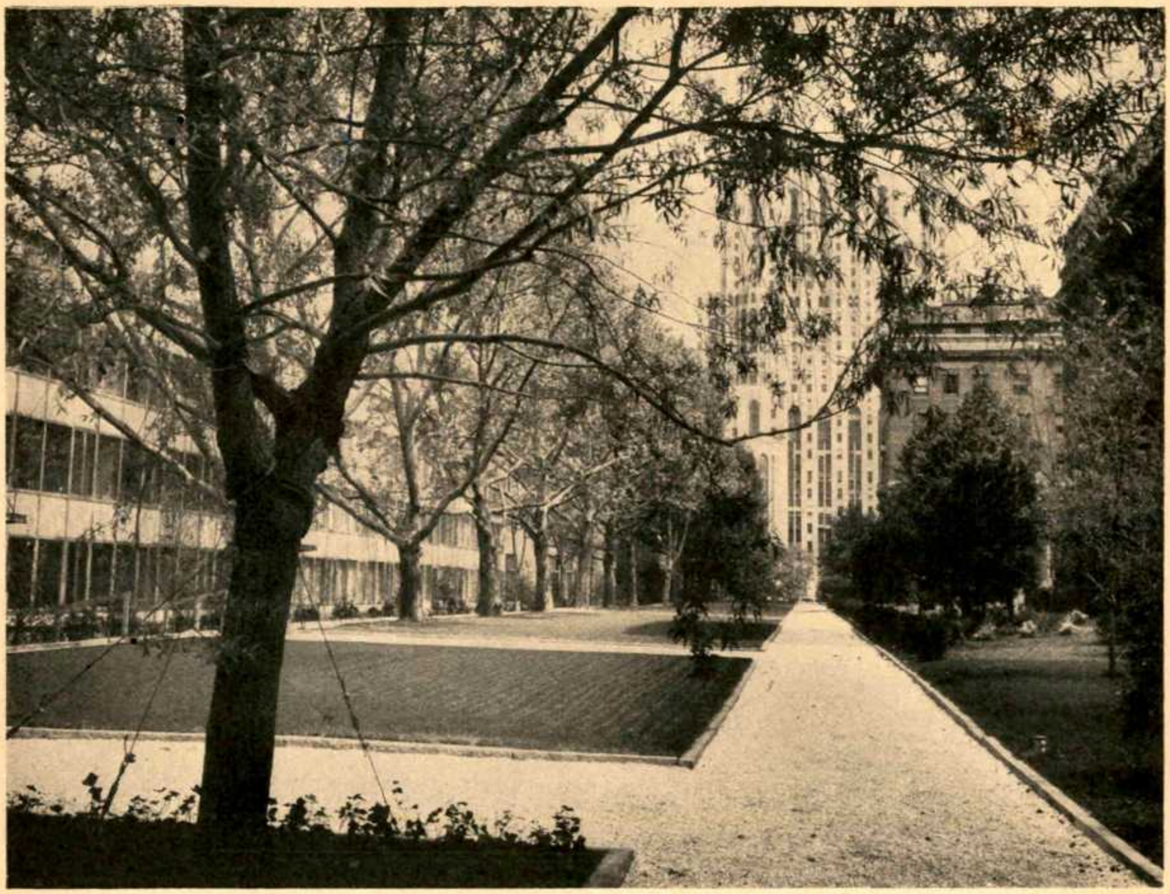

Fig. 3. View of the new campus area of the Rockefeller Institute, looking toward New York Hospital. On the left is the Graduate Students' Residence Hall and, on the right, one of the Institute's older laboratory buildings (Flexner Hall)

Rockefeller Foundation in 1913 and the Laura Spelman Rockefeller Memorial in 1918. The last two were merged in 1928. Thus father and son have, as Dr. Bronk said, "been unequalled in their sympathetic understanding, their selfless service, and the scope of their unrestricted, generous gifts in support of scholars and their corporate institutions".

Dedication of New Buildings and Campus

Five new buildings and the North and South Campus were dedicated during the afternoon of May 22. Of necessity in New York, though the buildings are large and spacious, the total area of the campus is comparatively small. This has much to recommend it ; for the tendency among some modern universities is to spread themselves over huge areas, thus rendering intercommunication inconvenient if not exhausting.

Caspary Hall contains an auditorium to hold five hundred, numerous seminar and conference rooms, and rooms for the Board of Trustees and senior administrative officers concerned with the educational activities of the Institute. The auditorium is dome-shaped, and its furnishings are of striking beauty. The acoustics are excellent.

Abby Aldrich Rockefeller Hall contains social halls, refectory, library, meeting rooms and private dining rooms for the friendly association of members of the faculty and their families. It also provides living quarters for visiting scientists so that this building may become an international scientific centre for meetings and the exchange of ideas. The air-conditioned residential suites leave nothing to be desired, and the library, refectory and lounges are adorned by some impressive, though controversial, examples of modern American art.

The President's House likewise fosters the development of the Institute as a centre of scientists in a great international city.

The Students' Residence Hall is designed to meet the needs of the most fastidious.

The South Laboratory (Fig. 2) is a huge building which will soon be offering comprehensive facilities for research in many fields.

The campus is charmingly landscaped (Fig. 3).

Of the older buildings, Founder's Hall, Flexner Hall and Theobald Smith Hall are devoted primarily to the housing of 109,000 sq. ft. of laboratories, most of which have been reconstructed and re-equipped within the past ten years. The Hospital, of fifty-six beds, serves as a laboratory for the study of the physiology of man and certain of the diseases which afflict him. Greenhouses provide approximately 10,000 sq. ft. of facilities for botanical research.

Welch Hall contains a library of more than 40,000 volumes, including an unusually fine collection of scientific periodicals. In this building there are also a large faculty dining hall, another for the women of the administrative, secretarial and technical staffs, and social rooms for both groups.

Other buildings comprising the Institute are the Jacques Loeb Laboratories in the Marine Biological Laboratory at Woods Hole, Mass., for those wishing to study marine organisms. Special facilities are also available in the research laboratories of the New York Botanical Garden for those members of the faculty who desire to use the extensive resources there.

Because of increasing dependence of modern scientific research on adequate technical facilities, many supporting services are maintained in order to facilitate and make more effective the work of the Institute. For example, the Animal House contains 40,000 sq. ft. of quarters for animals ranging in size from mice to horses. There are well-equipped shops for the construction of instruments and electronic equipment; whereas shops for machine work and cabinet work make possible the construction and maintenance of all laboratory equipment. Central facilities for electron microscopy, spectroscopic determinations, microanalyses, X-ray studies, photographic work and media preparation are among the many aids maintained for the general use of the various laboratories.

Publications

The Rockefeller Institute Press was established in 1958 and now publishes *The Journal of Experimental Medicine*, *The Journal of General Physiology* and *The Journal of Biophysical and Biochemical Cytology*. Reprints of recent publications are issued periodically as volumes of *Studies*. Events of general interest are published in *The Rockefeller Institute Quarterly*. Monographs and scientific texts are to be published by the Rockefeller Institute Press in association with Oxford University Press.

The celebrations of the first Convocation of the Rockefeller Institute were rounded off by a pleasant garden party in the grounds of the President's House.

In announcing his resignation from the presidency of the Board of Trustees of the Rockefeller Institute in 1950, Mr. John D. Rockefeller, jun., said he had always regarded "this enterprise as the most significant and the most permanent of any that my father established". It is certainly true that the world of scholarship, and especially of science and medicine, owes a great debt of gratitude to the Rockefeller family: particularly through the Rockefeller Institute is the world indebted to John D. Rockefeller, his son John D. Rockefeller, jun., and his son David Rockefeller.

To Dr. Detlev Bronk the world of science and learning will tender their congratulations and express deep admiration for his almost superhuman efforts to further the development and advancement of the Rockefeller Institute and especially for the foundation of this new graduate university.

EVOLUTIONARY SYSTEMS—ANIMAL AND HUMAN*

By Prof. C. H. WADDINGTON, C.B.E., F.R.S.
Institute of Animal Genetics, Edinburgh, 9

THE major advance in the theory of biological evolution since Darwin's day has been the rise of Mendelian genetics. It is scarcely an exaggeration to say that when Darwin wrote biology possessed no theory of inheritance. Since then, the existence of more or less discrete hereditary factors has been discovered, their position in the cell ascertained to be on the chromosomes in the nucleus, and the behaviour of these chromosomes analysed in great detail both in normal and in various more or less unusual conditions.

The whole of this complex of phenomena which are concerned with the manner in which hereditary determinants are passed on from one generation to the next may be referred to as the 'genetic system'. From the point of view of evolutionary theory three main points have emerged concerning it. The first is that the existence of discrete hereditary determinants safeguards variation against being lost if dissimilar animals cross-breed, as Darwin feared it might[1]. Indeed the fact that during the greater part of the life-cycle of most animals and plants the hereditary factors are present in the diploid condition implies that most organisms carry within them much greater potentialities for variation in their offspring than would appear at first sight. The second point, which is one that we owe primarily to the insight of Darlington[2], is that the genetic system itself can be regarded not only as an agent but also as a subject of evolutionary change, which is to say that the genetic system itself evolves. This I shall return to later.

The third point concerns the origin of new variation. It is essential to any theory of evolution that there must be some mechanism by which new variation is brought into being. Darwin was driven to speculate as to what this mechanism might be. In the absence of any understanding of how hereditary qualities are transmitted, he made no pretence that he had found a solution fully satisfactory to himself, although he was somewhat tempted by the theory, usually associated with the name of Lamarck, that characters acquired by organisms in the course of their lifetime might be transmitted to their offspring. Later experimental investigations have shown that in general this is not so.

Our knowledge of the genetic system, which is very extensive and detailed, forces us to the conclusion that the origin of new hereditary variation is to be found only in alterations and rearrangements of the atomic groupings out of which the hereditary factors of the chromosomes are composed. These alterations follow rules of stability which are still entirely unknown to us, but which must be properties of the hereditary molecules themselves and have little or no relation to the precipitating events by which the alterations were stimulated. One of the most firmly based doctrines of modern genetics is that mutation is a random process. I do not wish to challenge this, but I shall suggest later that some care is necessary in interpreting the word random.

---

* Substance of the Woodhull Lecture delivered at the Royal Institution on February 27.

In present-day biology, evolution is envisaged as resulting from the interaction between, on one hand, the genetic system characterized by random mutation, and on the other, natural selection. The evolutionary pressures exerted by these two factors are exhibited as being quite external to the nature of the organisms involved. The essential evolutionary pressure exerted by the genetic system is that of mutation, and mutation, it is explained, is a random process. Any explanation which might be offered for the nature of the mutational changes would have to be found, it is asserted, in the chemical composition of the genes and not in the nature of the complete biological organism in which these genes are carried. Mutation thus appears as essentially an external force to which the organism passively submits. Again, natural selective pressures are usually thought of as arising simply from the external environment. When the climate changes, a new predator appears, or industrial fumes blacken the tree trunks on which the animal lives, the populations of organisms concerned cannot, it is usually implied, do anything but submit to these pressures and wait until the equally uncontrollable process of mutation throws up a new hereditary variant which enables them to meet the environment's challenge more successfully.

The time seems to have come when we need to take into account two further aspects of the evolutionary mechanism[3]. In the first place, natural selective pressures impinge not on the hereditary factors themselves, but on the organisms as they develop from fertilized eggs to reproductive adults. We need to bring into the picture not only the genetic system by which hereditary information is passed on from one generation to the next, but also the 'epigenetic system' by which the information contained in the fertilized egg is expanded into the functioning structure of the reproducing individual. Each organism during its lifetime will respond in some manner to the environmental stresses to which it is submitted, and in a population there is almost certain to be some genetic variation in the intensity and character of these responses. Natural selection will favour those individuals in which the responses are of most adaptive value.

Two consequences can be expected to follow, and have in fact been demonstrated experimentally. In the first place, natural selection will build up genotypes which set going developmental mechanisms which easily respond to environmental stresses by the production of a well-organized modification which is of adaptive value. It will, as it were, build into the genotype a gun which is not only set on a hair trigger but which is aimed to hit the target when it goes off. In so far as such a developmental response becomes precisely delimited and easily initiated, it becomes the more likely to be produced by unspecified changes in the chemical nature of the hereditary substance. Mutations, which we can think of as random when we are considering the nucleo-proteins of the chromosomes, will have effects on the phenotype of the organisms which are not necessarily random, but which will be modified by the types of instability which have been built into the epigenetic mechanisms by selection for response to environmental stresses.

Since this is an unfamiliar point of view it may be as well to illustrate it by actual example[4]. If eggs of *Drosophila* are submitted to ether vapour shortly after laying, a proportion of them tend to have their development modified so that they produce a very peculiar phenotype, known as bithorax, in which the third segment of the thorax of the animal is transformed from its normal small and obscure structure into a duplicate of the large second thoracic segment. We can treat the response as though it were favoured by selection, and in each generation breed from those individuals in the population which respond to the stress in this way. When this was done with a population taken from a normal wild-type stock, it became apparent that there was some genetic variation of the capacity to respond in this manner. If selection favoured the response, the frequency with which it occurred increased from generation to generation, until after some time it became practically universal when the selected stock was submitted to the ether. After some time a new gene mutation occurred; this was a sex-linked factor which had not been present in the original stock. Its effect is that females homozygous for it lay eggs which tend to develop the bithorax phenotype. This is particularly striking when the factor is present in the selected stock, in which, as it were, the bithorax modification has been set on a hair trigger. If the factor is transferred into an unselected wild-type stock, the tendency to produce bithoraxes is very much reduced. We have here an example in which selection has built up a genotype which exhibits a particular type of developmental instability. A gene mutation has occurred which in the normal *Drosophila* would have only a very slight tendency to produce this phenotype, but which does so with considerable frequency in the selected stock. Thus, if one merely refers to such a gene mutation as 'random', one does not say by any means everything of interest which can be told about it.

The other main evolutionary effect of the epigenetic system depends on the fact that the development of organisms is usually to some extent canalized, in the sense that even though it may become somewhat modified in response to an environmental stress, it also exhibits a tendency to reach its normal end-result in spite of disturbing circumstances If a strain of animals is selected over many generations for its capacity to respond in a particular way to a certain stress, a set of genotypes will be built up in which this response is easily exhibited when the environmental stress is applied, but the developmental resistance to change may be sufficient to ensure that some of it is still retained even if the stress is removed. If that happens, we should have a system which exactly mimics the inheritance of an acquired character, but one which depends not on the direct induction of a hereditary variation, in the manner suggested by Lamarck, but on selection operating on the genetical structure of the population.

Again, there is a practical chapter and verse for such a suggestion in the experiments with the bithorax modification. After rather more than 20 generations of selection for ease of response to ether vapour, the strain had reached a condition in which a high proportion of bithorax individuals appeared even when the ether treatment was not given. This is the process which I have spoken of as the 'genetic assimilation' of an acquired character.

To obtain a complete picture of the evolutionary system, we need to take into account one further set of factors. These may be spoken of as the exploitive system. Animals—the following considerations do not apply so directly to plants—are usually surrounded by a much wider range of environmental conditions than they are willing to inhabit. They live in a highly heterogeneous 'ambiance', from which

they themselves select the particular habitat in which their life will be passed. Thus the animal by its behaviour contributes in a most important way to determining the nature and intensity of the selective pressures which will be exerted on it. Natural selection is very far from being as external a force as the conventional picture might lead one at first sight to believe.

The problems which arise in this field have as yet been rather little studied, even in the biological field, where the relations are likely to be relatively simple. This area of study is, however, likely to be of particular importance for eugenics, since human behaviour is incomparably more elaborate than that of the majority of animals, and in particular the behaviour associated with choice and the seeking of particular goals is much more fully developed.

Biological evolution, then, is carried out by a mechanism which involves four major factors: a genetic system, an epigenetic system, an exploitive system, and a system of natural selective pressures (Fig. 1). All these factors undoubtedly persist in man, but, just as the genetic system is itself subject to evolution, so in broader terms we may say that this whole four-component evolutionary system, of which the genetic system is only a part, itself evolves. The human situation is characterized by an enormously important step in the evolution of the evolutionary mechanism. Indeed, it might be not unreasonable to define humanity by this fact. In man, the processes of teaching by the older members of the population, and learning by the younger ones, have been carried to an incomparably higher pitch than is found in any of the prehuman forms of life, where they play only a relatively minor part, for example, in the determination of bird song, and a few other examples. In man, they have developed not only to highly effective person-to-person learning, as in apprenticeship, but, by the invention of writing and other more recent devices, to an extremely elaborate system by which the whole conceptual understanding of the past is made available to present recruits to human society. We have here what in effect amounts to a new mode of hereditary transmission. It may be referred to as the cultural or 'socio-genetic' system.

Within the past few millennia, the human race has acquired capacities which, in the non-human world, could only have been obtained as the results of evolution. To give a banal example, one may mention the ability to fly. Man has certainly not achieved this capacity by waiting for genes to turn up which have transformed his fore-limbs into wings. In fact there is no evidence that changes in the pool of genes available to the human race had any specific effect on the development of the human conquest of the air. This does not mean, of course, that the genes were irrelevant. Human inventiveness and skill, just like any character of any organism, are produced by the interaction of genes with one another and with the environment during development. But so far as one can tell, all the genes necessary to produce men capable of inventing methods of flying had been present in the human population for many generations. What the development of flight was waiting for was not some change in the genetic system, but some change in the cultural system.

When one attempts to consider the problem of human evolution, the type of phenomena which should rise to one's mind are all the most crucial changes which have occurred between, say, the late Stone Age and the present. It is not in any important sense the slight changes in bodily structure which differentiate us from Cromagnon man which make the greatest impression. Human evolution has been in the first place a cultural evolution.

It is important not to overlook this first impression of what human evolution is all about. It is clear that for an understanding of how the human race has come into the possession of those characteristics which we now think most valuable in human life, a theory is needed which is primarily one of cultural evolution.

It seems probable that in the cultural evolutionary system there are parallels for many of the factors operative in the biological system. For example, parallel to the process of gene mutation there is the arising of new ideas capable of cultural transmission; and there are undoubtedly processes, fulfilling a function similar to that of natural selection, which determine whether newly arisen ideas will in fact be perpetuated in future generations or not. How far is the arising of culturally novel ideas a process which can be characterized as random, even in the restricted sense in which we have seen this term should be used in the biological sphere ? What is it that determines the intensity of the natural selective pressure for or against the preservation of new ideas ? Again, items capable of cultural transmission such as ideas, techniques or skills do not occur in isolation but are found in co-ordinated groups. Can we find here some parallel to the genetic phenomena of linkage and recombination ? The cultural exploitive system, the system of choosing and modifying the environment, is also obviously very highly developed. Again, cultures reacting to external stresses may become particularly liable to modification in certain directions, exhibiting phenomena similar to those we have attributed to the epigenetic system. All these parallels, however, remain as yet very incompletely worked out. It would probably be profitable to pursue them[6].

Although it would seem prudent, when faced by a phenomenon of human evolution, first to consider by what cultural means it has been brought about, it is also very necessary to inquire into the biological or genetical phenomena associated with it. This is, however, exceedingly difficult. Suppose a marked change takes place in the gene pool of the human population; under what circumstances should we expect this to have an important influence on the essential cultural achievements of the group concerned ? It is extraordinarily difficult to find any factual evidence, since most examples of marked changes in the gene pool of a population involve the immigration or emigration of individuals who carry with them not only their transmissible genes but also their transmissible culture. For example, one may postulate, as Darlington[5] has done, that the emigrants from Ireland in the middle of the past century carried out of the population many genes for various types of socially effective behaviour, leaving the home population impoverished. But in practice the existence of these genes is only hypothetical, and even if they did exist the emigrants also undoubtedly carried with them culturally transmitted tendencies to vigorous behaviour.

There are a few cases, however—for example, when Jewish populations have immigrated into or out of a country, with whose population they have not engaged in extensive cross-breeding, but on whose life they have exerted a considerable influence—in which one may deduce that this influence has been primarily a cultural rather than a genetic one. Even if we were to make the unsafe assumption that it is their genes which endow the Jewish people or the Chinese with great ability in trade, the effect which a small number of Jews or Chinese may have on the economic existence of the people surrounding them can only be the result of cultural rather than genetic transmission. Again, the rapidity, in terms of numbers of generations, with which many steps of evolution take place (such as, say, the formation of the characteristic United States culture out of an extraordinarily mixed European immigrant population) is scarcely compatible with the operations of the genetic evolutionary mechanism and, it would seem, must in the main be attributed to the actions of the human cultural evolutionary system.

When we can discern cultural differences between two human groups, does the main responsibility of these lie with the system of cultural transmission or with that of genetic transmission ? Again, from an *a priori* point of view one must expect differences in both systems to be involved, and it is exceedingly difficult to assess the relative importance of the two contributing factors. It is quite clear that races such as the West Africans, the Maoris and the Chinese, differ genetically from Europeans. Some of these genetic differences are obviously expressed in skin colour; there must surely be others, more difficult to detect. But is there any reason, for example, to suppose that it is the differences in the gene pool between the Chinese and the European populations which have caused the one to develop a social system based on such relatively unindividualistic systems as Confucianism and Buddhism and the other a civilization inspired by such a different system of thought and feeling as Christianity ? I see no *a priori* reason to suppose anything of the kind; nor is there sufficient factual evidence to establish such a conclusion.

Again, one can find examples, particularly in quite recent times, in which human populations have undergone important changes in periods of time which seem much too short to allow of noteworthy alterations in their genetic endowment. The change in West Africa from the conditions described a century ago, to the present highly sophisticated and technologically competent modern societies, can only have been accompanied by exceedingly small, if any, changes in the general gene pool. One of the most striking of such changes, and one of the very few that has been carefully studied by a highly trained specialist, is that of the Manus people of the Admiralty Islands in the Pacific, studied by Margaret Mead[7]. This transformation from a palæolithic to at least the beginnings of a modern society has taken place within a lifetime; that is to say, it has involved *no* genetic alteration. It is a most remarkable example of how powerful the cultural evolutionary system may be.

These examples suggest, in my opinion, that in producing the changes of the kind which we consider of major importance in the evolution of mankind, the cultural system of transmission usually contributes incomparably more than the genetical. Even when we can be certain that genetical changes have occurred, as, for example, in the comparison between Africans and Europeans, there are only one or two examples in which these changes can be shown to have any practical importance.

The genetic system of a population, as Lerner[8], in particular, has pointed out, shows a considerable power of resistance to factors such as natural or artificial selection which attempt to alter it. I have argued that the epigenetic system shows similar characteristics of unresponsiveness[3]. One might expect, and I think the evidence suggests, that cultural systems also have some tendency to stability. This is probably correlated to some extent with their size. The fantastically rapid transformation of Manus society occurred in a minute population of only a few thousands; one could scarcely expect the fifty millions of Nigeria or the five hundred millions of China to alter as rapidly. One cannot, therefore, always expect the processes of change mediated by the cultural evolutionary system to occur in a shorter time than those which might be carried out by the genetic system. It is only in favourable cases that the critical evidence emerges which shows that steps in human evolution can occur at a rate much faster than the genetic mechanisms could bring about. Cultural phenomena which involve stability over long periods need not necessarily, on *a priori* grounds, be attributed to the genetical system; there is no reason to doubt that cultural transmission may operate over many generations. Such questions will only be answerable when we find further methods of gathering empirical data which will enable us to distinguish the contributions of the two information-transmitting systems in each particular case.

OBITUARIES

Sir Stanley Angwin, K.C.M.G., K.B.E., D.S.O., M.C.

The death on April 21 at the age of seventy-five of Sir Stanley Angwin brings to a close a remarkable military and engineering career. Educated at Queen Mary College, he received his practical training with Messrs. Yarrow and Co., the shipbuilders. In 1906, at the age of twenty-three, he entered the Engineering Department of the Post Office, a step which took him in the course of fifty years to the highest engineering and administrative positions in the telecommunications field; he became engineer-in-chief of the Post Office in 1939, chairman of Cable and Wireless in 1947 and finally chairman of the Commonwealth Telecommunications Board from 1951 until 1956.

It was provident that Angwin was engineer-in-chief during the Second World War, for the part played by telecommunications was vital and demanded extreme co-operation with the Fighting Services. Angwin had a foot in both the Civil and Services' camps, for he had been associated with the Army Signals since the inauguration of the Territorial Army. His Unit, which he raised as the Lowland Division Telegraph Company, was mobilized in 1914 to form the 52nd Divisional Signal Company and served throughout the First World War in Gallipoli, Egypt, Palestine and France. He was awarded the D.S.O. and M.C., and those who knew his scant personal regard for air raids in 1940 can readily imagine the value and influence of his imperturbable personality as a young commander in the earlier War. His association with Army Signals continued between the Wars, first in command of the 44th Home Counties Divisional Signals and finally as deputy chief signal officer for the Supplementary Reserve.

With this background, Angwin was in an excellent and accepted position to assess and direct the provision of the many long-distance circuits and installations required for the defence of the United Kingdom. The demands for Post Office services were overwhelming, and sometimes competing, particularly for air defence, and later for the U.S. Armed Forces, and the preparations for *D* Day. All this in the face of bomb damage, and incessant repairs, provided a formidable task of direction, while at the same time Angwin fostered the release of technical staff to the Forces for the build-up of the signal staffs and units overseas where their professional knowledge was indispensable.

Between the Wars Angwin's work had been associated with the development of the Post Office and Commonwealth radio services. On his return from the First World War he was appointed to the wireless section of the Engineer-in-Chief's office. There he found, in an era of development, just those opportunities needed to match his many talents. On the technical side he found scope for applying his knowledge and experience in the design and construction of high-power radio stations at Cairo, Leafield and Rugby; and was closely connected with the establishment in 1927 of the first trans-Atlantic telephone service and in the subsequent development of short-wave radio telephone services to all parts of the world.

Angwin's ability in negotiation was equally outstanding. This frequently led to his appointment as chairman of committees, particularly those dealing with controversial matters, at many international telecommunication conferences.

He was chairman of the Radio Research Board during 1947–52. In 1945 he accompanied Lord Reith on a mission to the members of the Commonwealth to discuss changes in Commonwealth communications, leading to the nationalization of Cable and Wireless, Ltd., and to the setting up of the Commonwealth Telecommunications Board.

On retirement from the Post Office, Angwin became in January 1947 the first chairman of Cable and Wireless, Ltd., in its new role, and in April 1951, at the invitation of the partner Governments, followed Lord Reith as chairman of the Commonwealth Telecommunications Board. In 1950, as chief technical adviser to the Board, he had presided over a meeting of technical and traffic experts from all parts of the Commonwealth, which was the first Commonwealth gathering of its kind. He was chairman of the Board for five years, filling this office with his usual distinction and doing much to further Commonwealth co-operation in all spheres of telecommunications. In 1954 he headed a delegation of the Board to Australia and New Zealand. In 1955 he presided over a second successful technical and traffic conference in London, but in 1956, owing to ill-health, he felt obliged to retire.

As engineer-in-chief of the Post Office, Angwin was knighted in 1941 and made K.B.E. in 1945 for his war services. For his services to international telecommunications he was made K.C.M.G. in 1957. He was president of the Institution of Electrical Engineers during 1943–44, Faraday Medallist in 1953 and made an honorary member in 1956. He became a Fellow of Queen Mary College, London, in 1946 and received an honorary degree of doctor of science from the University of London in 1953.

Lady Angwin was an ideal support to him throughout his career. With their family they made their home in Welwyn Garden City, where his charming house and garden must have been a welcome haven in the midst of his exacting duties.

His friends will remember his quiet and seemingly casual manner, his kindly disposition and yet the confidence he could inspire and the force of his leadership. GORDON RADLEY

Mr. L. E. Harris

MR. LAWRENCE ERNEST HARRIS, a leading authority on fen drainage, died on April 5 at Cambridge, aged sixty-six. The Newcomen Society for the Study of the History of Engineering and Technology has suffered a very severe loss by his unexpected death during his second year as president.

After leaving Mercers School, London, Harris studied at the City and Guilds Engineering College, South Kensington, during 1910–12 and won a Mitchell scholarship. He obtained his practical training with C. Isler and Co., London, artesian well engineers. During the First World War he served in the Royal Fusiliers and the Machine Gun Corps and, as a lieutenant, was invalided out due to war wounds. Having taken a refresher course at King's College, London, Harris joined Sulzer Bros., Ltd., as an estimating engineer in their London office. After three months at their Winterthur Works, he went to India in 1923 as the firm's manager, and for thirteen years was responsible for the sale and installation of many Sulzer steam and diesel engines, pumps and electrical machines in pumping and power stations. Returning to England, he was appointed district manager and engineer for the Sulzer organization in the Fen area in 1937, specializing in fen drainage and pumping machinery. He also installed Sulzer pumps for the Somerset River Board's drainage schemes. He lived in Leeds until 1947, and then in Histon, Cambridge, holding the same appointment until his death.

Harris was intensely interested in the history of his subject, and his authoritative book, "Vermuyden and the Fens", was published in 1953. He wrote the chapter, "Land Drainage and Reclamation" in Vol. 3 of "A History of Technology", published in 1957, and contributed to the Newcomen Society "Sir Cornelis Vermuyden, an Evaluation and an Appreciation" and "Some Factors in the Early Development of the Centrifugal Pump, 1689–1851". In his presidential address, "A Neglected Genius of Seventeenth Century Technology", he paid honour to the inventor, Cornelius Drebbel (1572–1633), of Alkmaar. One of Harris's last interests was to ensure that the beam engine and scoop-wheel installed in 1831 at Stretham, near Ely, by the Butterley Company, should be permanently preserved, as it is the last surviving example of the introduction of steam power for fen drainage. The formation of the Stretham Engine Preservation Trust in 1958 was due to him; he was elected the first chairman of the Trustees and wrote the appeal this year for an endowment fund. His many friends hope the appeal will succeed in its object and that it will be a permanent tribute to his memory. He is survived by his widow, Mrs. Kathleen Harris, and his two sons, Michael and John, both engineers. A. STOWERS

NEWS and VIEWS

Special Assistant for Science and Technology to the U.S. President: Prof. G. B. Kistiakowsky

PROF. GEORGE B. KISTIAKOWSKY, a distinguished physical chemist, who succeeds Dr. James R. Killian (*Nature*, 181, 384; 1957) as special assistant for science and technology to the President of the United States, spent four years at Princeton University after receiving the Dr.Phil. in Berlin in 1925. He went to Harvard University in 1930, progressing quickly to a professorship in 1937, which he has held ever since. Following early researches on the ultraviolet spectra of polyatomic molecules, and on thermodynamics, after the Second World War he applied shock and detonation waves to the study of chemical problems, determining the heat of dissociation of nitrogen; and employed soft X-rays and mass spectrometers to investigate the phenomena occurring in shock fronts. His most recent studies have been in classical chemical kinetics. Honours that have been accorded to him include the American Medal for Merit (1946), the British Medal for Service in the Cause of Freedom (1948), and the Nichols Medal of the American Chemical Society (1947).

As a civilian scientist during the war years, Prof. Kistiakowsky headed the explosives division of the Manhattan Project, was consultant to the Office of Scientific Research and Development, and adviser to the United States Army on scientific problems of a military character. His wide experience and ability have been recognized by his election to membership in the Philosophical Society and the National Academy of Sciences. In recent years, as a member of the President's Scientific Advisory Committee, his activities and interests have been focused on national scientific policy and on science as a force and a balance in international affairs.

Metallurgy at Manchester: Prof. F. C. Thompson

PROF. FRANK CHARLES THOMPSON, who is to retire from the chair of metallurgy and directorship of the Metallurgical Laboratories of the University of Manchester on September 30, will then have served on the Senate of the University for thirty-eight years. Prof. Thompson graduated in the University of Sheffield in 1911 and was awarded the Mappin Medal; he then served on the staff of the University of Sheffield until 1919, after which he held the Royal Society Sorby Research Fellowship at Sheffield for one year before being called to the chair at Manchester.

At Manchester, Prof. Thompson rapidly established himself as a bold leader of research in his own special subject of the plastic deformation of metals and gave detailed consideration to the atomistics of plastic flow at a time when few physicists realized that a meaningful problem existed in this field of study. He also, and perhaps in the long run this is more important, established himself as a wise academic statesman and a truly sympathetic 'father' to his department. It was a paternity which protected and encouraged the younger members of his staff while they went their own way in pursuit of their own problems, and gave to the students a basic sense of security spiced with intellectual challenges. The qualities which served the University so well were unstintingly given to the councils of professional bodies, particularly to the Institute of Metals and the Institution of Metallurgists, and he served as president of both these bodies.

Prof. C. R. Tottle

Charles Ronald Tottle, who is to succeed Prof. F. C. Thompson, graduated in 1941 from the honours school of metallurgy at the University of Sheffield with first-class honours. Joining the English Electric Co., Ltd., he was for some years in charge of the metallurgical laboratories of that firm at Rugby. For five years from 1945 he had academic and teaching experience as lecturer in metallurgy at King's College, Newcastle upon Tyne. From 1950 onwards his experience has been in various branches of the atomic energy field, first as scientist in charge of metallurgical developments at Springfield, where, after promotion to senior principal scientific officer, he was appointed assistant director of the Research and Development Branch. In 1951 he was transferred to the new Culcheth Laboratories, of which, in 1955, he was appointed deputy head. In that year he went to Dounreay as head of research and development, and last year became the deputy director and head of the Reactor Division.

Until 1952, Mr. Tottle's publications were mainly concerned with cast iron and residual stress. Two publications dealt with the plastic flow and deformation of cast iron and a third with the general problem of nucleation of cast metals at the mould face. His more recent contributions have naturally been in the atomic energy field and deal with the effect of alloying elements on the creep of metals and the physical and mechanical properties of niobium and its alloys. Much of his work during this period is still 'classified'.

Botany at Aberdeen :

Prof. James Robert Matthews, C.B.E.

Prof. J. R. Matthews, regius professor of botany in the University of Aberdeen, retires at the end of this session. Students and colleagues alike have much cause to thank Prof. Matthews for the unfailing cheerful encouragement and wise council so freely given over a long and distinguished career. Educated at Perth Academy and the University of Edinburgh, Matthews early displayed a deep interest in taxonomy and ecology which has remained throughout his career and has placed him in the forefront of botanists concerned with the problems of the origin and distribution of plants in Britain. Before his appointment as regius professor at Aberdeen, Matthews served as lecturer at Birkbeck College (1913–16) and at the University of Edinburgh (1920–29) and as professor of botany at the University of Reading (1929–34). During the First World War he contributed to our knowledge of the protozoology of dysentery, serving as a temporary protozoologist at the Liverpool School of Tropical Medicine (Western Command). Matthews has given freely of his time to national and local committees as a member of the Nature Conservancy and for a time as chairman of the Scottish Committee, as chairman of the Macaulay Institute for Soil Research (since 1947) and of the Scottish Horticultural Institute (since 1952). He was elected president of Section K for the Brighton meeting of the British Association in 1948.

Prof. Paul Egerton Weatherley

Dr. P. E. Weatherley, who is to succeed Prof. Matthews at Aberdeen, was born in Leicester and received his early education at Wyggeston School; he gained an open scholarship in natural science to Keble College, Oxford, and graduated in the honours school of botany in 1939. Elected to a Keble research scholarship to study fungal metabolism he acted as a part-time demonstrator. Awarded a Colonial Office Scholarship to the Imperial College of Tropical Agriculture (1940), he obtained the A.I.C.T.A. (1942) and was posted to Uganda in the Department of Agriculture. He was in charge of an experimental farm at one of the government research stations and acted as advisory botanist. There he turned his attention to the problems of water relationships of plants and has pursued this as a major research project on his return to Manchester (1947–49) and at Nottingham since 1949. This has culminated in the design and installation of a highly efficient climatological wind tunnel capable of providing a wide range of precisely controlled environments for growing plants (see *Nature*, 183, 94; 1959). The work has been supported by the Nuffield Foundation and the University of Nottingham. The technique used by Kennedy and Mittler to study the feeding habits of aphids has been applied by Weatherley to study the nature and the movement of solutes in plants. He brings to his new appointment a well knit and vigorously pursued field of experimental botany. Through service on the Board of the Faculty of Science and on University committees, he has acquired at first hand a knowledge of the problems of administration facing universities in this expanding phase of higher education. Apart from botany, Weatherley has a wide range of interests, including painting, hill walking and Scottish country dancing. To his duties as regius professor he brings a wide knowledge of experimental botany, a keen and critical interest in the expanding fields of botany and an appreciation of the difficulties and requirements of students in the modern world of science.

Euratom : British Nuclear Energy Attaché

Mr. D. H. Hill, of the U.K. Atomic Energy Authority, has been appointed resident nuclear energy attaché to Mr. A. H. Tandy, the U.K. Government's representative to the European Atomic Energy Community (Euratom) in Brussels. The Government appointed a permanent representative to Euratom last year. The agreement between the Government and Euratom, which was signed in London on February 4, 1959, provides for close collaboration between the parties for the promotion and development of the peaceful uses of atomic energy within the Euratom community and Great Britain. The nuclear attaché will act as adviser to the British representative and will keep in touch with nuclear developments in all the six member countries of Euratom. Mr. Hill has been a member of the staff of the Authority's Industrial Group since 1956.

Royal Society Artificial Earth Satellites Programme

In accordance with the Prime Minister's announcement on May 12, the Royal Society through its British National Committee on Space Research is engaged in preparing on behalf of the Lord President of the Council a programme of scientific experiments to be carried out in a series of artificial Earth satellites. University departments and other research organizations wishing to propose scientific experiments for incorporation in the programme are invited to communicate with the Assistant Secretary, The Royal Society, Burlington House, London, W.1.

Milk Marketing Board

In 1944 a plan was prepared for an artificial insemination service in all areas of England and Wales except those covered by the pioneer centre that had begun with Cambridge in November 1942. From a 'cow-population' map, territorially convenient blocks of 60,000 cows were ringed off as areas in which to build centres. Centres were to be located on the basis of thirty bulls to each centre (the maximum size because of the risk of foot-and-mouth disease); on the estimate that ultimately 50 per cent of cows in each area would be offered for artificial insemination, and in the belief that 1,000 cows would be inseminated from each bull annually. The last two estimates, thought by many at the time to be far too optimistic, have been confirmed by subsequent history. Already, demand in some areas has resulted in more than ninety cows in every one hundred being inseminated, and the use of bulls is already more than twice the original estimate. In 1959—appropriately the centenary year of the publication of Darwin's "The Origin of Species"—the Milk Marketing Board has announced that 10 million cows have been produced by artificial insemination during the past fourteen years. The way this has been achieved, and the administrative structure of the Milk Marketing Board, is set out in a well-illustrated publication called "Breeding 10,000,000 Cattle" (H.M.S.O.). The Board is rightly proud of its work and tells its story with lively enthusiasm. The fact that a cattle raiser can now breed for a change in the market merely by lifting a telephone is a tribute to the Board and the adaptable British farmer.

New Bell Laboratories

A new laboratory, costing 20 million dollars, will be built by Bell Telephone Laboratories at Holmdel, New Jersey, to meet the expanding need for research and development. Bell Laboratories is the research and development organization for the Bell Telephone System, and employs nearly 11,000 people. The new building will be on a 430-acre site which has been owned by Bell Laboratories since 1929; it has been designed by Eero Saarinen. The first portion of the building is expected to be occupied by late 1961.

Journal of Molecular Biology

This journal is to be published six times a year by the Academic Press, Inc. (London), Ltd. (1, No. 1; April 1959. Subscription £5 per volume), and although published in English, papers in French and German will be accepted. The study of molecular biology attracts scientists from numerous disciplines and with its rapid expansion the problem of correlating results obtained by the specialist has become increasingly difficult. The advent of this new journal with an editorial policy of publishing papers on "the nature, production and replication of biological structure at the molecular level and its relationship to function" should be of great value to workers in this field. With one exception the eight papers and two letters in the first number of the *Journal of Molecular Biology* fall into the framework of molecular biology as defined in the instructions to authors. It is to be hoped that the exception does not represent the thin end of the wedge and that the editors will in future restrict publication to papers dealing with molecular biology and not allow the periodical to develop into another journal of general biochemistry, of which there are already a sufficient number.

The United States National Museum

The annual report of the United States National Museum for 1957–58 (pp. iv+150. Washington, D.C.: Government Printing Office, 1958) records that rapid progress in planning the building for the Museum of History and Technology permitted erection to start in the summer of 1958. The building will be of a rectangular shape having an extended platform to form a terrace at first-floor level. It is significant to note that planning for the interior was undertaken by the architects from draft designs and details submitted by the Museum staff. This is the fifth year of the modernization programme, and the Halls of Health, North American Indian and Eskimos, native peoples of America, and military history have been dealt with. A striking exhibit is that depicting the home life of an average Arapaho Indian family some seventy-five years ago: while the warrior and his wife entertain visitors within a completely furnished tipi, the children play with toys outside and a woman prepares pemmican.

Museum and Art Gallery, Durban

The annual report of the Museum and Art Gallery at Durban for 1957–58 (pp. 19. Durban: Durban Museum and Art Gallery, 1958) states that, in spite of a staff below establishment, much work on display for the public and the re-housing of the scientific research collections has been carried out during the year. The group showing the white-tailed wildebeest and warthog has been re-designed, and work has commenced on the Kruger Park waterhole exhibit. Owing to the vacant keepership in the Art Gallery, work in that branch of the service has been virtually at a standstill, although a few temporary exhibitions have been arranged. In the Old House Museum the court dress and accessories of Sir James L. Hulett have been placed on exhibition, and an interesting tollgate erected in Durban in 1867 has been re-erected in the grounds.

U.S. Atomic Energy Commission: Grants for Training in Radioisotope Technology

Mr. John A. McCone, chairman of the U.S. Atomic Energy Commission, has announced that grants amounting to 251,704 dollars to twelve American colleges and universities will be made for education and training in radioisotope principles and technology. An increase in the number of technical graduates who are able to use radiation as an industrial tool is expected to contribute significantly to the expanding uses of radioisotopes and radiation.

The grants are the first of a series of awards to be made under the Commission's new radioisotope technology training programme. The first series also includes a grant to the University of California, for the purchase of equipment to be used in three industrial radioisotope training courses this summer at Berkeley. Further information can be obtained from the Director, Office of Isotopes Development, U.S. Atomic Energy Commission, Washington 25, D.C.

National Research Council of Canada Support for Universities

INFORMATION about the National Research Council of Canada's current programme of university support for science, engineering and medicine is contained in a "Report on University Support, 1958–59" (pp. ii + 143. Ottawa: National Research Council, 1958. 50 cents), which explains the programme, shows how it is conducted, and lists the recipients of scholarships, fellowships and associateships and the direct grants in aid of research. There is also a list of travel grants. Expenditure on scholarships in 1958–59 is estimated at 490,000 dollars, of which 475,000 dollars is for science and engineering and 15,000 dollars for psychology; on fellowships in science and engineering, 360,000 dollars; in medicine, 100,000 dollars; in dentistry, 12,000 dollars; and on medical associateships, 120,000 dollars. Of the grants in aid of research, 2,350,000 dollars is for science and engineering, and 1,250,000 for medical research; 135,000 dollars is allocated for the Prairie Regional Committee, 400,000 dollars for the Atomic Energy Control Board, 136,000 dollars for associate committees, and 366,000 dollars for general research grants. Grants of 43,000 dollars to assist travel by members of university staffs and of 146,580 dollars for special activities at universities bring the total to 5,908,500 dollars, while of a further 749,500 dollars for indirect university support, including administrative costs of the support programme, estimated at 175,000 dollars, 260,000 dollars are for the publication of the *Canadian Journal of Research.*

University College, London: Report for 1957–58

THE annual report of University College, University of London, for 1957–58 includes the report of the chairman of the College Committee and that of the provost. This gives a brief account of some of the research work in progress, and a full list of publications by members of the College, arranged by faculty and department, occupies 34 pages of the report. Of the 2,827 undergraduate students and 803 postgraduate students 609 and 338, respectively, were in the faculty of science, 201 and 76 in that of engineering and 190 and two in that of medical science. Of the total, 2,943 were from the United Kingdom, 352 from the the British Commonwealth of Nations overseas and 335 from other parts of the world.

Laboratory Animals Centre

THE organization and administration of an animal division for research purposes was considered at a symposium arranged by the Laboratory Animals Centre of the Medical Research Council Laboratories on May 5, 1958. The papers, which have now been published (Laboratory Animals Centre: Collected Papers, Vol. 7; 1958. Pp. 107. Carshalton, 1958. 10*s*.), dealt with the economics and efficiency of an animal division, the relation of an animal division to a research division, the problems of equating supply and demand, the organization of the field laboratories at the University of Sheffield, the scientific research within a laboratory animals division, the staffing of an animals division and animal technician training.

A New Method of Particle-counting on the Electron Microscope

IN making estimates of particle counts by electron microscopy it is necessary for the particles from a known volume to be uniformly distributed over the grid in order to get a random sample of the material. In practice, however, this is difficult to achieve, and Backus and Williams (*J. App. Phys.*, 21, 11; 1950; *J. Amer. Chem. Soc.*, 71, 4052; 1949), as a compromise, have counted all the particles in small droplets, the size of which was determined by the number of polystyrene latex particles known to be contained in a unit volume of the solution. This technique has recently been improved upon by Nixon and Fisher (*Brit. J. App. Phys.*, 9, 66; 1958), who used a high-pressure spray gun made of metal, and intended to work with small droplet sizes; it can be used with as little as 0·2 ml. This decreased the size of the droplet, thus making it possible to use much higher magnifications without sacrificing the ability to obtain a picture of each droplet-trace entire on one frame.

Another approach to the problem has now been made by Dr. D. Gordon Sharp, in collaboration with Ivan Sorvall, Inc., Norwalk, Connecticut, in which virus from a known volume is deposited uniformly over a known area of agar jelly by means of centrifugation. The apparatus consists essentially of a centrifuge rotor with eight numbered compartments and a stainless steel cover. It contains eight stainless steel-housed 'Perspex' cell assemblies, and in each cell is placed a 1 cm. square of 2 per cent agar jelly. 1 ml. of the virus is added to each cell and the rotor spun in the centrifuge at 20,000 r.p.m. After spinning the rotor, the cells are opened and the agar squares, which have the virus particles uniformly distributed on their surfaces, removed to dry. A film of collodion is poured over the agar surface, allowed to dry and floated off on water. The floating collodion is then picked up on an electron microscope grid, and the sample is ready for counting. The advantages of this method seem to be that it is simple to use, and, because there are eight cells, eight different samples can be dealt with simultaneously.

Micro-Spot Cathode-Ray Tube

THE new Ferranti 5/71 *CM* micro-spot cathode-ray tube has a line-resolving power comparable with that of a well-designed lens and marks an important advance in electron optics. The tube can display all the detail that a lens could project on to the same area and can be used to produce equally clear photographic prints. In systems employing the flying-spot scanning technique, however, resolution in the line direction is limited, for a given scanning speed, by the phosphor decay time, and unless this can be reduced without sacrificing light output it will not be possible to take full advantage of the 5,000 lines in such applications.

Hausaland Erg

FROM field work and the interpretation of air photographs, A. T. Grove (*Geog. J.*, 24, 528; 1958) advances the view that the landforms of the plains that stretch along the southern border of the Sahara were shaped by erosion and deposition under climatic conditions that differed greatly from the present, associated with deep weathering, water erosion and the formation of extensive lakes in humid periods followed by phases of much wind action and dune building in the intervening arid periods, matching the alternation of ice and river action in high latitudes. He directs attention, however, to the danger of matching glacial periods with tropical pluvials and to the conflicting views regarding the climatic sequences in the tropics during Pleistocene times in relation especially to the definition, expansion, or movement of the margins of major arid regions such as the Sahara. Much of the key to this fascinating problem may well lie hidden in the ancient Saharan erg and other sand accumulations of the desert fringes.

Injury-feigning Behaviour of Wood-pigeons

DESCRIBED as infrequent in the Handbook of British Birds, two apparently related cases of injury-feigning among wood-pigeons (*Columba palumbus*) have been recorded by C. S. Payne (*The Bedfordshire Naturalist*, 12 ; 1959). Disturbed by a pointer dog in Kempton Park, a wood-pigeon flew straight over the grass at a height of only 1 ft. from the ground, in a manner similar to that of a common sandpiper flying over water. Near the dog was a fully grown and feathered young pigeon which had presumably fallen to the ground before it could fly. Six days later the dog again disturbed an adult wood-pigeon which was "floundering along in the grass as if it had no legs, and progressing a few inches at a time, very awkwardly, by means of its wings". When Payne attempted to pick the bird up it rose buoyantly into the air and flew away. On this occasion no young bird was found. This may have been the same adult which had previously been observed, the distraction behaviour of which had been retained.

Urwick Medal for Management Studies

THE Polytechnic Management Association has instituted a new annual award, to be known as the Urwick Medal, for presentation to the best final-year student in the diploma course in management studies at the Regent Street Polytechnic, London. The first award will be made at the end of the session 1958–59. The Association's members are past and present students of management at the Polytechnic.

Royal Society of Tasmania : Officers

THE following were recently elected to office in the Royal Society of Tasmania for the year 1959 : *President*, The Governor of Tasmania ; *Vice-Presidents*, Mr. L. W. Miller, Dr. D. Martin ; *Council*, Hon. Mr. Justice Crisp, Mr. R. M. H. Garvie, Dr. E. Guiler, Mr. K. D. Nicolls, Mr. M. S. R. Sharland, Mr. J. W. C. Wyett, Mr. W. F. Ellis, Mr. G. H. Stancombe ; *Hon. Treasurer*, Mr. G. E. A. Hale ; *Hon. Auditor*, Mr. A. M. Hewer ; *Hon. Secretary and Librarian*, Dr. W. Bryden ; *Librarian*, Miss E. M. Geddes.

Harwell Reactor School Courses

EIGHTEEN standard or full courses have to date been held at the Harwell Reactor School, and Standard Course No. 19 will start on August 31, and continue until December 18. Altogether, 951 students from 32 different countries have so far attended these courses, which began in September 1954 and are designed to train engineers in the techniques of reactor construction and operation, particularly in connexion with nuclear power stations. Half the places at each course are allocated to overseas students, and a fee of £250 exclusive of accommodation is charged. A special course for senior technical executives will be held during September 21–October 1. This is the ninth course of this kind and the fee is fifty guineas exclusive of accommodation. Application forms and details of both courses can be obtained from The Principal, Reactor School, Atomic Energy Research Establishment, Harwell, Didcot, Berks.

Announcements

PROF. J. A. L. MATHESON, Beyer professor of engineering in the University of Manchester, has been appointed as the first vice-chancellor of the new Monash University, Melbourne.

PROF. N. J. PETCH, professor of metallurgy in the University of Leeds, has been appointed to the chair of metallurgy at King's College, Newcastle upon Tyne. For a note on the work of Prof. Petch see *Nature*, 178, 347 (1956).

MR. A. L. BACHARACH has been elected president of the Nutrition Society in succession to Dame Harriette Chick. Prof. R. G. Baskett, Mr. F. le Gros Clark, Dr. H. N. Munro and Dr. F. Yates were elected ordinary members of Council. Dr. R. J. L. Allen (Beecham Foods, Ltd., Brentford, Middlesex) is honorary secretary.

THE Oliver Bird Prize for 1958 has been awarded to Prof. M. C. Shelesnyak of the Weizmann Institute of Science, Israel, in recognition of his work on the role of histamine in the decidual response of the endometrium and the discovery that ovum-implantation can be suppressed by the presence of histamine antagonists in the uterus before nidation.

A CONFERENCE on Co-operative Phenomena and Phase Transitions, organized by Prof. G. S. Rushbrooke on behalf of the Physical Society, will be held at Kings College, Newcastle upon Tyne, during July 6–7. There will be four sessions, devoted to : thermodynamics and phenomenology ; melting and liquids ; quantal fluids ; and lattice interactions (Ising and Heisenberg models). Further details may be obtained from Miss E. Miles, Physical Society, 1, Lowther Gardens, Prince Consort Road, London, S.W.7.

THE ninth Canadian High Polymer Forum will be held at the Guild Inn, Toronto, Ontario, during October 26–28. The Forum is sponsored by the National Research Council of Canada in co-operation with the Chemical Institute of Canada, and is devoted to all aspects of polymer science. Authors wishing to submit papers for presentation at the Forum should write to the programme chairman, Dr. L. A. McLeod, Research and Development Division, Polymer Corporation Ltd., Sarnia, Ontario, Canada. Titles and abstracts of approximately 300 words will be required by August 1. General information concerning the Forum can be obtained from Dr. M. H. Jones, chairman, Ninth Canadian High Polymer Forum, Ontario Research Foundation, 43 Queen's Park, Toronto 5, Ontario.

THE Australian Branch of the Institute of Physics will hold a Conference on Solid State Physics in Melbourne during August 17–22. Some forty physicists from Australia, four from New Zealand, ten from the United States, about five from the United Kingdom, and two from Canada will read papers on original work. The papers offered fall mainly into the fields of lattice and electron theory of metals, low-temperature physics, imperfections and plastic deformation, crystal growth, and surface phenomena. Other fields of solid state physics will also be discussed. Further information can be obtained from the convener, Dr. W. Boas, Division of Tribophysics, Commonwealth Scientific and Industrial Research Organization, University of Melbourne, Carlton, N.3, Victoria, Australia.

FUNCTION OF THE RUMEN

THE 123rd meeting of the Nutrition Society was held at the Royal Veterinary College, London, under the chairmanship of Dr. D. P. Cuthbertson, director of the Rowett Research Institute, on March 7, when a symposium on "Rumen Function" took place. In his opening remarks the chairman described the theme as one of great fundamental and practical interest where the microbiologist, biochemist, physiologist, animal husbandman, veterinarian, and members of the feeding stuffs trade could meet and learn much through the exchange of knowledge and concepts.

Dr. C. C. Balch (National Institute for Research in Dairying, Shinfield) introduced the subject by describing the structure of the ruminant stomach and the movement of its contents. In the course of its development the ruminant stomach has achieved an efficient microbial digestion of plant fibres and also of practically all other plant constituents, and with this goes the syntheses of microbial polysaccharide and protein and also certain vitamins. The structure of the four portions of the ruminant stomach which emerge from the embryonic stomach —the rumen, reticulum, omasum and abomasum—was described. The abomasum with its typical gastric secretory function corresponds to the stomach of non-ruminants; in very young ruminants it is as large as the rumen.

Co-ordinated movements of the omasum, reticulo-omasal orifice, reticulum and rumen can be recorded pneumatically or seen radiographically. These were described by Dr. Balch.

During eating, the food boli are deposited in the anterior rumen, where they rapidly merge. By the end of a meal of hay most of the new food is to be found tightly packed in the dorsal sac as a relatively dry, fibrous layer, whereas the ventral region will contain a layer of more fluid digesta. The reticulo-rumen never empties, and, in fact, in the stall-fed animal rarely contains less than half its capacity. The amounts found in grazing animals are considerably less. The amount of food given, and especially the amount of hay, is a major factor influencing the length of time residues remain in the rumen: there is a slight tendency for concentrates and succulents to pass out of the reticulo-rumen more rapidly than roughages. According to Gordon, the onward passage of particles of hay is greatest during rumination. The transfer of digesta to the omasum is a continuous process.

Dr. B. H. Howard (Rowett Research Institute, Aberdeenshire), in his contribution on the metabolism of carbohydrates by rumen bacteria, first described the various techniques which have been used: (1) *in vivo* studies; (2) 'artificial rumen' preparations; (3) washed cell suspensions; (4) direct microscopic observation including use of fluorescing antibodies; (5) pure culture; and (6) 'enrichment culture' experiments.

Cellulose is the most important of the polysaccharides fermented in the rumen, and xylan occurs in close association with it. Most of the rumen cellulolytic and xylan-decomposing bacteria are very strict anaerobes and some require carbon dioxide and/or rumen liquor. Cellulose yields mainly acetic, lactic and succinic acids in pure culture fermentations, and xylan gives fatty acids, from formic to butyric. Mixed rumen organisms, on the other hand, convert both substances mainly into varying proportions of acetic and propionic acids.

The main rumen starch-fermenter is *Streptococcus bovis*, chains of cells of which can be seen attached to decomposing starch grains. It produces only an α-amylase, and lactic and acetic acids are the chief fermentation products. The same organism will also ferment the oligo- and poly-saccharides containing fructose, found in grass and root crops.

Rumen micro-organisms show a striking capacity to synthesize polysaccharides either internally as iodophilic deposits of 'starch-like' material, or externally as capsules or slime-layers. It is doubtful if the material leaving the rumen to enter the omasum contains any significant amount of digestible carbohydrate of microbial origin.

Lactic and succinic acids added to the rumen are quickly decomposed, yielding mainly propionic acid. Rumen acetic and butyric acids are interconvertible. Formic acid is rapidly decomposed in the rumen to carbon dioxide and hydrogen, which further react to give methane; some five rumen-volumes per day arise from this reaction normally.

In his paper on the utilization of protein by the dairy cow, Dr. M. J. Head (National Institute for Research in Dairying) said that as a result of the action of the ruminal micro-organisms, the value of the nitrogenous moiety of the feed to the dairy cow is not so dependent on its amino-acid structure or its proportion of true protein as is the case with a single-stomached animal. The ammonia produced during the fermentation is either utilized for the growth of organisms which are later digestod to give nutrients of high biological value, or is absorbed through the rumen wall into the blood-stream and largely wasted. This loss has not been sufficiently considered in evaluating protein feeds for ruminants.

The classical assessment of the biological value of a protein is complicated in the case of a ruminant by the fermentation in the rumen, as has been shown by the work of Chalmers and Synge. The greater the loss of ammonia from a protein, the greater the significance to the animal of the amino-acid structure of the feed protein residues leaving the rumen unattacked.

A comparison of the various oil-cake residues normally used as protein sources for dairy cows on the basis of daily *in vivo* rumen ammonia concentration curves did indicate differences between the cakes. A similar classification of these protein sources could be made on the basis of the proportion of their total nitrogen soluble in 1 *M* sodium chloride solution.

While theoretically the most desirable type of protein for a ruminant is one of low solubility in the rumen and yet of high biological value for a single-stomached animal, two further questions need consideration with reference to practical feeding. First, is the dairy cow normally rationed sufficiently stringently for any of these theoretical improvements to be seen to advantage; and secondly, may it not be more economic to feed a theoretically wasteful protein source if it still supplies cheaper units of biological value ?

In discussing lipids in relation to rumen function, Dr. G. A. Garton (Rowett Research Institute) prefaced his paper by a consideration of the nature of dietary lipids. The lipids present in feeding stuffs such as grass, hay, silages and concentrates were considered with special reference to the C_{18} polyunsaturated fatty acids (linoleic and linolenic) which form a large part of the total fatty acid content.

Events in the rumen were considered first with reference to the hydrogenation of unsaturated fatty acids, which occurs to a considerable extent under the influence of the rumen bacteria. This results in the production, *inter alia,* of stearic acid which, following intestinal absorption and deposition, may well account for the characteristic 'hardness' of ruminant depot fats.

Recent findings on the hydrolysis of triglyceride fats in the rumen by a bacterial lipase were then outlined. These demonstrate that most of the fatty acids entering the rumen as glycerides reach the abomasum and small intestine in the free state—a situation markedly different from that in monogastric animals in which partial lipolysis takes place in the small intestine. The fermentation of the liberated glycerol (to yield propionic acid) was briefly discussed.

The ruminant does not appear likely to derive any of the so-called 'essential' fatty acids from the lipids of its rumen bacteria. Thus it appears that, if the ruminant requires 'essential' fatty acids, they must be of dietary origin and must also escape hydrogenation in the rumen.

In his contribution on milk composition in relation to rumen metabolism, Dr. J. A. F. Rook (National Institute for Research in Dairying) indicated that the observations of Powell in 1938–41 provided convincing evidence that the fine grinding of the entire roughage in a ration or, alternatively, a considerable reduction in roughage intake and an increase in the concentrate feed, reduced the percentage and yield of fat without affecting total milk production. This specific effect on fat secretion has been fully confirmed by Balch, Balch, Bartlett, Cox and Rowland at Shinfield. Milk of unusually low fat content was observed by McClymont to result from cows grazing on young herbage or fed on kale, concentrates and limited amounts of hay or straw, that is, diet short of roughage. The operative factor is the physical condition of fibrousness rather than the presence of fibre.

The depression in the milk fat secretion of cows on low roughage diets has invariably been associated with a change in fat composition. Milk fat in the cow and other ruminants is distinguished from the milk fat of other species, and from animal depot fats in general, by a relatively high content (up to 20 per cent on a molar basis) of short-chain (C_2–C_{10}) acids, and when a reduction in fat secretion occurs the proportion of these acids is correspondingly reduced. Some reduction in the weights of higher saturated (largely palmitic and stearic) and also unsaturated (largely oleic) acids secreted is also observed.

Additions of sodium acetate (500–1,500 gm./day) or acetic acid have produced an almost complete recovery in the fat content of milk, but individual animals have failed occasionally to show a response to sodium butyrate. It is held to be the change in the production of acetic and propionic acids that has generally been responsible for the depression in milk fat synthesis.

The role of the protozoa was outlined by Dr. Margaret Eadie (Rowett Research Institute) in her paper on some aspects of rumen ciliate protozoa. According to Dr. Eadie, the basic nature of the association of rumen ciliates with rumen function is a complex one still not clearly understood, but their study is valuable because of the one justified generalization: that certain species of ciliates have been found in the rumen of all normal adult ruminants so far examined.

In general, diet appears to have the greatest effect upon the ciliate population, and variations are so large that no acceptable average figure can be given nor can the ciliate protein contribution be accurately assessed. This may be as high as 20 per cent of the total host requirement, and qualitative studies have indicated that the ciliate protein is of higher nutritional value than the rumen bacterial protein.

Comparisons of faunated and non-faunated animals have so far shown no serious effects on those free from ciliates, but it has yet to be ascertained whether advantage from a ciliate population would appear under conditions of stress. In recent work in collaboration with Dr. Preston at the Rowett Institute, experiments are in progress to determine, by variation of the roughage content of the weaning ration, how soon ciliates may be permanently established in early-weaned calves and whether this is advantageous.

Numerically the oligotrich organisms, particularly *Entodinium* spp., make up the largest proportion of most populations. So far, the holotrichous organisms, which are fewer in number, have been most closely studied and the information of the biochemical and nutritional properties of these organisms suggests that equally interesting information should accrue from similar studies of the oligotrich ciliates.

In his paper on the treatment and prevention of bloat with anti-foaming agents, Mr. C. S. W. Reid (Plant Chemistry Division, Department of Scientific and Industrial Research, Palmerston North, New Zealand, at the Physiological Laboratory, Cambridge) pointed out that if stable foams are generated during fermentation, the elimination of gas from the rumen is impeded and bloat (tympanites) may result. His paper reviewed work carried out in New Zealand on the use of anti-foaming agents in the treatment and prevention of acute bloat in grazing dairy cattle. Administration of foam-breaking substances—fats and oils, certain detergents and other surface-active materials but not silicones—was the only consistently useful treatment found. Materials at present recommended for field use are peanut oil and emulsified ruminant tallow in doses of 120–150 gm. fat. Anti-foaming agents were also effective when given prophylactically. Pasture spraying proved to be a reliable control measure and has been used on New Zealand farms over four seasons. It has also been notably successful in preventing bloat on irrigated pastures in Australia.

Detectable anti-foaming activity is present in the rumen contents and can be shown to be affected by the activity of the micro-organisms. However, apart from indicating the probable complexity of the situation, observations so far have not revealed obvious correlations between lipid intake, anti-foaming activity and bloating.

Dr. A. T. Phillipson (Rowett Research Institute) in his paper on the rumen in relation to the animal considered first the extent of digestion in the reticulum and rumen. He pointed out that several estimates have been made of the extent of digestion in the reticulum and rumen which are based on the lignin ratio and which suggest that the quantity of food constituents disappearing ranges from 43 to 83 per

-cent in cattle and that a similar but rather narrower range has been found in sheep. Most of the material disappearing is carbohydrate. It is more difficult to assess the extent of disappearance of nitrogen-containing materials as the secretions augment the nitrogen of the food, but it appears that considerable losses occur from the rumen in both cows and sheep and presumably these represent the absorption of ammonia. However, losses in the intestine are more extensive when compared with the apparent digestibility of nitrogen for the whole alimentary tract.

Estimates of fatty acid production in the rumen show that they are quantitatively important. The recent work of Armstrong and Blaxter at the Hannah Dairy Research Institute indicates that at levels of feeding up to maintenance the value of the mixture of short-chain fatty acids to the animal as a source of energy is fairly constant irrespective of the quantities of each individual acid absorbed. For production purposes, rations that favour the formation of propionic and butyric acids should be more valuable than those that favour the production of acetic acid. The proportions of propionic and butyric acids increase as the concentrate part of the ration increases in cattle. In particular, starch-rich food increases the proportion of propionic acid. As yet, very little is known of the peptic and intestinal phases of digestion.

In the second part of his paper, Dr. Phillipson dealt briefly with the absorptive capacity of the intestinal tract. One of the conditions of terrestrial life is the necessity of conserving water and sodium, and the ruminant is unusually good at carrying out these two tasks.

The quantities of water and sodium secreted in the saliva alone are far greater than the quantities excreted in the faeces. The contribution made by other digestive juices still needs investigation and is likely to be considerable. Both sodium and water are known to be absorbed from the rumen and omasum, while there is no doubt that absorption also occurs along the remainder of the tract, particularly in the large intestine. It is of particular interest that in conditions of sodium depletion the sodium content of the saliva is lowered and its place is taken by potassium ; there is also a diminution of the volumes secreted. A study of the rates of turnover of body constituents such as water, sodium and other elements and nitrogen in various circumstances may help in the end to understand why occasionally things go wrong.

The final paper of the symposium was by Mr. J. K. D. Dow (Unilever, Ltd.) on the application of recent scientific information through the feeding-stuffs industry.

Studies on the absorption of fatty acids in the rumen, and the connexion with hormone metabolism, indicate dietary means of regulating milk production and quality and of curing conditions such as ketosis. Chemical tests enable processed protein materials to be classified according to the needs of the animals for which they are best suited. The feeding-stuffs industry has already made use of research into the vitamin and mineral requirements of ruminants. Further research on the effect of these on roughage utilization is awaited.

Recent work on antibiotic supplements for calves has indicated results which are not applicable through the industry in the present stage of legislation. This case demonstrates the wide view which is demanded of the research worker to-day, particularly when some manufacturers may depend entirely on published scientific evidence in formulating new feeding stuffs. However, it is doubtful whether fundamental research workers have adequate facilities for testing their results under practical conditions. This problem offers a profitable field for consideration by the feeding-stuffs industry, because co-operation between the research worker and the manufacturer is essential to the efficient functioning of the industry and, ultimately, will ensure that the farmer reaps the fullest benefit.

D. P. CUTHBERTSON

NUCLEAR FUEL CYCLES

THE Institute of Physics, in collaboration with the British Nuclear Energy Conference, held a symposium on "Nuclear Fuel Cycles" at the Institution of Civil Engineers, Westminster, on January 22 and 23. The symposium was opened by the president of the Institute of Physics, Sir George Thomson, who welcomed some 250 members and visitors, including delegates from eight European countries. He stressed the importance of fuel cycles in relation to the large nuclear power stations now under construction in the United Kingdom. These would prove competitive with coal-fired stations only if their uranium fuel were employed in the most efficient manner.

The symposium was divided into three sessions, the first of which considered the basic physics of long-term reactivity changes and nuclear fuel cycles, the second was concerned with the optimization of fuel cycles, and the third session discussed relevant operational problems. The chairman of the first session was Dr. J. V. Dunworth (Atomic Energy Research Establishment, Harwell). The first paper presented was that by Dr. H. Rose and Mr. J. J. Syrett (Atomic Energy Research Establishment, Harwell) on "Long-term Reactivity Changes", which described the basic physical processes occurring as natural or slightly enriched uranium is irradiated in large graphite-moderated thermal reactors. The importance of these changes was emphasized since, together with considerations of metallurgical damage, they would determine the irradiation-level at which the fuel must be replaced. The overall reactivity-changes with irradiation are determined mainly by the small net difference between the large changes arising from the burn-up of uranium-235 and the formation of plutonium-239, making the problem unusually sensitive to all the relevant nuclear data. Furthermore, the plutonium isotopes formed in the irradiated uranium have large resonances in their fission and capture cross-sections at low neutron energies. The prediction of their rates of reaction with neutrons therefore demands a detailed knowledge of neutron spectrum conditions to an extent unnecessary in assessing the initial reactivity of the reactor. For these reasons, present predictions rely considerably upon integral measurements which are made on irradiated fuel elements. Much of this work has been carried out using the *Gleep* pile oscillator at Harwell, where data have been accumulated from uranium which has been highly irradiated in the Windscale, NRX and Calder Hall reactors. Typical predictions were displayed of the long-term reactivity changes to be expected for an individual fuel element in the Calder Hall type reactor, and the dependence of the reactivity curve upon several important design parameters was also illustrated.

In the ensuing discussion, Mr. P. W. Mummery (Atomic Energy Research Establishment, Harwell) explained that the long-term reactivity changes occurring at Calder Hall have been observed directly. Their interpretation was difficult since they applied to a complete reactor, and it was necessary to allow for the effects of different irradiation-levels throughout the reactor and the variation with irradiation of the control-rod effectiveness. Even so, there were some grounds for satisfaction that these measurements were in reasonable agreement with the *Gleep* experiments. Finally, he emphasized the very high accuracy on the basic nuclear data which is demanded for a purely theoretical approach to these problems.

For a given flux distribution and fuel-cycle scheme, the long-term reactivity changes of an entire power reactor may be found by suitably weighting the contribution from each fuel element. This was discussed in the second paper, by Mr. S. E. Lewis (Nuclear Power Plant Co. Ltd.). He considered the basic theory of 'once-through' fuel cycling, in which the fuel supplied to the reactor has a constant composition and does not contain any materials produced during the irradiation of previous charges. Mr. Lewis showed how an equilibrium state is reached in a small region where the flux is uniform and maintained constant, and demonstrated the factors determining the reactivity of the region and the whole reactor during the approach to the equilibrium state. The equilibrium state is determined when fuel is added and removed continuously in such a way that in any region of the reactor all irradiation-levels are represented between zero and the maximum allowable. Certain basic fuel-cycle schemes were outlined, some of which necessitated fuel movement within the reactors. It was concluded that the delay of commencement of continuous fuel replacement could be economically advantageous, and warranted closer study.

It is necessary to investigate the local behaviour of reactor flux and heat output in the small region considered in the previous paper, as the fuel elements will have different irradiation histories. This problem was discussed in a paper on perturbations due to fuel cycles which was presented by Dr. J. G. Balfour, Dr. D. L. Booth and Mr. R. S. Bulloch (Atomic Power Projects). One-group perturbation theory was applied to the calculation of axial flux changes in a single channel caused by the non-uniform irradiation and temperature, and by axial fuel shuffling within the channel. An improved method was then developed in which the non-linear one-group diffusion and heat transfer equations were solved numerically, this being applicable even when the perturbations were large. Axial distributions of flux and of coolant temperature were illustrated both before and after neutron irradiation of the fuel. A final section of this paper described the use of the Feinberg method for estimating local channel-to-channel variations of power and flux during a continuous fuelling scheme. The work suggested that although the fission cross-section of a fuel element varied considerably over its life due to build-up of plutonium, the heat output maintained a more constant level due to the increased depression of the neutron flux.

In the discussion, Mr. Syrett pointed out that the choice of fuel cycle had an important bearing upon reactor economics. In the approach to equilibrium which lasted several years, large sums of money could be saved by a judicious choice which would reduce fuel requirements and investment charges. He explained the potential advantages of radial shuffling for giving improvements during the approach period and in the equilibrium state.

In summing up the session, the chairman emphasized the importance of reaching a practical and economic fuel-cycling procedure for the Central Electricity Generating Board reactors, one which would have to take into account many different technologies. It was imperative that during the first few years of operation of these reactors, intensive operational research should be performed to improve our knowledge of fuel-cycling problems.

The second session (chairman, Mr. L. Rotherham of the Central Electricity Generating Board) contained two papers concerned with the optimization of fuel cycles. The first, by Mr. P. R. J. French and Mr. C. S. Lowthian (A.E.I.–John Thompson Nuclear Energy Co. Ltd.), considered a once-through equilibrium fuel cycle. The influence of the fuel cycle on the optimization of the reactor design through the lattice parameters was studied, and a relationship developed between burn-up of fuel and the initial neutron spectrum conditions. The effect of enrichment upon fuel life was also discussed, together with the allocation of excess reactivity to increase reactor output or fuel life.

The second paper was presented by Dr. P. J. Grant, Mr. W. Oswald and Mr. P. D. D. Russell (General Electric Co. Ltd.) This examined economic factors affecting the choice of fuel cycle for nuclear power stations, and underlined certain aspects often overlooked. Optimization of the fuel cycle is only a part of the overall optimization of cost per kilowatt hour, which depends partly upon local conditions. Neutron economy was important, but might sometimes conflict with monetary economy. As an example, flux flattening with steel absorbers and attendant loss of neutrons at the reactor centre could yield longer fuel life and reduce power costs. The economy of enrichment, plutonium production and fabrication costs was considered, as were the present prices of nuclear fuels. The advantages of axial fuel shuffling in the Calder Hall type reactor, and the necessity for continuous charge and discharge schemes, were also discussed. It did not appear generally economic to reduce deliberately the irradiation-level below the metallurgical limit.

Mr. G. E. Darwin (Babcock and Wilcox Ltd.) commented in discussion on the importance of this limit. The uranium and canning materials would not stand up well to fuel shuffling and the necessity to operate under differing physical conditions. This would result in reduced metallurgical limits depending upon the shuffling schemes, and it was inadvisable to assume a constant limit in fuel-cycle considerations. Mr. Syrett pointed out that delaying the onset of the equilibrium charge – discharge scheme could reduce fuel requirements, and since potential savings of the order of £1 million per reactor were possible this provided an incentive for such schemes. He asked Mr. French and Mr. Lowthian whether large computer programmes were preferable to their analytical approach to fuel cycle considerations. Mr. Lowthian replied that it might be difficult to analyse all the information provided by the machines, but agreed that machine effort was extremely useful. In response to a question by Dr. G. Davis (Israel), Mr. Mummery stated that one could not dismiss fuel cycling and on-load charge – discharge machines as luxuries, since these provided a potential reduction of the order of a factor of two in fuel costs as well as making it possible to discharge burst cartridges without losing output.

A paper on the operational problem associated with fuel cycling was presented by Mr. J. C. C. Stewart and Dr. N. L. Franklin (Risley) in the third session, for which Prof. J. Diamond (University of Manchester) was in the chair. The authors pointed out that unlike some other industries, conservative operating procedures based upon precisely specified codes of practice cannot be expected because of the rapidity of development in the reactor field. It is essential in their opinion to choose an irradiation life-time which represents a compromise between metallurgical failure-rate and reduction in fuel costs. Sums of the order of £1 million per charge might depend upon this choice. They believed that the reactor operator and fuel manufacturer must carry out a sequential experiment to study the development of fuel cycles and ultimate life of fuel elements, using the actual power reactor itself as the test vehicle. This would also allow for the introduction and testing of subsequent types of fuel element as they are developed. The authors pointed out that this would have considerable influence upon the fuel fabrication facilities required.

Dr. C. P. Haigh (Central Electricity Generating Board) remarked that as a reactor operator he had special problems to consider such as on-load refuelling. The high capital costs of reactors had to be offset by low fuel costs and a high load factor. Shut-down of one reactor for one day would cost £8,000, while a prolonged shut-down involving a complete fuel discharge would cost around £2 million. Thus the reactor operator must be somewhat conservative initially in relation to fuel cycling. Experience would be accumulated gradually on reliability, before large-scale use would be made of complex fuelling schemes.

The closing remarks at the end of the symposium were made by Mr. P. W. Mummery, who explained that the main aim of the symposium had been to indicate the implications of the basic physics problems involved in nuclear fuel cycles on the design and operation of reactors. Compromises are necessary between conflicting requirements from many fields such as physics, metallurgy, engineering, heat transfer, operational simplicity, etc. The potential advantages of various types of fuel cycle had been indicated, on the assumption that various kinds of fuel movement within the reactor were possible and that the irradiation life was limited only by reactivity. Although such cycles could not be used initially, until more experience and more information had been gained, the design of reactors should be flexible to allow for developments such as these. It would be many years yet before the best fuel cycle was established for the Calder Hall type reactor. He looked forward to a time, three or four years hence, when actual operating experience of fuel cycling on different systems might be reported at a similar symposium.

The papers presented at the symposium and a summary of the important discussion will be published in the July issue of the *Journal of the British Nuclear Energy Conference*.

THE ROYAL AERONAUTICAL SOCIETY

AWARDS FOR 1958

THE following awards have recently been made by the Royal Aeronautical Society: *Honorary Fellowship* has been conferred on Prof. J. Ackeret (professor of aerodynamics at the Federal Technical College, Zurich), Sir William S. Farren (technical director, A. V. Roe and Co., Ltd.), S. B. Gates (chief scientific officer and consultant to the director of the Royal Aircraft Establishment); *Honorary Companionship* has been conferred on E. C. Bowyer (director and chief executive of the Society of British Aircraft Constructors), Sir William Hildred (director-general of the International Air Transport Association).

Silver Medal of the Society has been awarded to Dr. E. A. Watson, director of Joseph Lucas (Gas Turbine Equipment), Ltd., for his achievements in the development of turbine engine combustion and fuel systems; *Society's Bronze Medal* to D. G. King-Hele, of the Royal Aircraft Establishment, Farnborough, for his contributions to Earth satellite orbital theory; *British Gold Medal for Aeronautics* to R. S. Stafford, technical director, Handley Page, Ltd., for his outstanding practical contributions to aircraft design; *British Silver Medal for Aeronautics* to D. J. Farrar, chief designer, Guided Weapons, Bristol Aircraft, Ltd., and Dr. N. H. Searby, manager, Guided Weapon Research and Development, Ferranti, Ltd., for their practical contributions to the development of guided weapons; *Wakefield Gold Medal* to K. A. Wood, superintendent in charge at the Atomic Weapons Research Establishment, Orfordness, for his practical achievement in the development and application of electronic aids to all-weather approach and landing; *R. P. Alston Medal* to A. W. Bedford, chief test pilot, Hawker Aircraft, Ltd., for his contributions to the technique of flight testing high-speed aircraft; *N. E. Rowe Medal*, for the best lecture given before any branch by a member of a branch, to J. Dunham, Rolls-Royce, Ltd., for his paper on "Damage to Axial Compressors" given before the Derby branch of the Society; *Simms Gold Medal* to Mr. R. P. Probert, deputy director, Engine Test Facilities, National Gas Turbine Establishment, for his paper on "Ram-Jets"; *George Taylor (of Australia) Gold Medal* to Mr. H. L. Cox, of the National Physical Laboratory, for his paper on "The Application of the Theory of Stability in Structural Design"; *Edward Busk Memorial Prize* to Mr. T. R. F. Nonweiler, of The Queen's University, Belfast, for his paper on "The Man-powered Aircraft

—a Design Study"; *Orville Wright Prize* to D. A. Spence, of the Royal Aircraft Establishment, Farnborough, for his papers, "The Lift on a Thin Aerofoil with a Jet-augmented Flap" and "Some Simple Results for Two-dimensional Jet-flap Aerofoils"; *Herbert Ackroyd Stuart Memorial Prize* to Mr. A. A. Lombard, director of engineering, Aero-Engine Division, Rolls-Royce, Ltd., for his paper on "Thinking about Aircraft Engines"; *J. E. Hodgson Prize* to Mr. J. E. Allen, head of Aerodynamics, Project and Assessment Department, Weapons Research Division, A. V. Roe and Co., Ltd., for his paper, "From Aviation to Astronautics"; *Branch Prize* to Mr. B. D. Blackwell, engineering manager, Bristol Aero-Engines, Ltd., for his paper on "Some Investigations in the Field of Blade Engineering"; *Navigation Prize* to Mr. C. M. Cade, of the Research Department of Kelvin and Hughes, for his paper on "Radio-Astronomy and Navigation"; *Usborne Memorial Prize* to Dr. J. S. Przemieniecki, of Bristol Aircraft, Ltd., for his paper on "Matrix Analysis of Shell Structures with Flexible Frames"; *Pilcher Memorial Prize* to Mr. A. W. Kitchenside, of Vickers-Armstrongs (Aircraft), Ltd., for his paper on "The Effects of Kinetic Heating on Aircraft Structures".

NEW NATURE RESERVES IN BRITAIN

THE Nature Conservancy has recently announced the establishment of four new nature reserves and one forest nature reserve.

The Rhinogs Nature Reserve. The Harlech dome and its borders display the thickest succession of Cambrian rocks to be seen in Britain. It forms a region of desolate and almost uninhabited moorland with high, rugged block-like mountains where the Rhinog Grits break the surface. The two principal peaks are Rhinog Fawr (2,362 ft.) and Rhinog Fach (2,330 ft.). The new reserve covers two blocks of these uplands, lying on either side of Bwlch Drws Ardudwy about five miles east of Harlech, which together total about 991 acres; it is hoped that it will ultimately be extended to include other areas of outstanding scientific interest in the area. The first of these blocks comprises the northern slopes of Rhinog Fawr from the peak down to about 1,066 ft., and the second includes the peak and north-eastern slopes of Rhinog Fach down to the 1,000-ft. contour. The terrain is rugged and wild in the extreme, with a considerable amount of exposed rock in the form of steep crags, broken slopes and block screes. A flock of wild goats, thought to be of domestic origin, frequents the Bwlch Drws Ardudwy area, and pine martens have been seen there in recent years.

Compared with other parts of Snowdonia, the Rhinogs are relatively lightly grazed by sheep, and this may be related to the abundance and luxuriance of heather which extends on these hills from about 600 ft. to the summits. The rocky, well-drained slopes up to the 1,500-ft. contour are covered with dense heather, mixed here and there with bilberry, both reaching 5 ft. in height in the more sheltered situations. The less rocky well-drained areas bear patches of acidic hill grassland, mainly of the *Agrostis–Festuca* type, with some bracken. Wherever hollows and stream flushes occur small bog patches are found, and the wettest ground is occupied by blanket bog with peat up to 4 ft. deep. The small summit plateaux and the steep craggy uppermost slopes of the two Rhinogs bear much block scree, and here the heath forms dense prostrate mats with unidirectional growth away from the prevailing south-west winds.

Access to the reserve is unrestricted, but those wishing to collect specimens or to carry out research should apply for permits to the Regional Officer for North Wales, The Nature Conservancy, Y. Fron, The Crescent, Upper Bangor, Bangor, Caernarvon.

Coed Dolgarrog Nature Reserve, which lies about seven miles south of Conway, is an excellent example of an oak wood on the drier north-eastern side of Snowdonia; many of the trees are intermediate in kind between the sessile and pedunculate oak. Viewed from the floor of the Conway Valley, these woods are probably the most impressive in North Wales; they clothe a precipitous slope which falls from 1,000 to 100 ft. It is unlikely, because of the topographical features of the area, that the woods have been subjected to any form of intensive land use. The reserve, most of which lies within the Snowdonia National Park, covers 170 acres and has been established under a lease from the Central Electricity Generating Board.

Coed Dolgarrog is of particular interest ecologically because of the variety of underlying rocks and the clarity with which their effects on the vegetation are displayed. The central part of the wood lies on lime-rich volcanic ash and has a luxuriant ground flora including much dog's mercury, slender false-brome and sanicle. At higher altitudes elsewhere in Snowdonia this particular kind of rock bears a rich arctic–alpine flora which makes Cwm Idwal and other parts of the district of great botanical interest. The southern and northern portions of the wood, on a hard acidic rhyolite, present a striking contrast, having a grassy ground flora often associated with bracken and sometimes with short bilberry and mosses.

Also included within the reserve are the Ardda alder woodlands, which extend along the northern bank of the Afon Ddu and represent an extension of Coed Dolgarrog into the upland country beyond the steep valley slopes of the Conway. This section is at a higher altitude, being between 750 and approximately 850 ft., with a correspondingly higher annual rainfall—about 60–70 in. as compared with 50 in. for the main body of Coed Dolgarrog. The woods occupy a gently sloping upland valley, which is thickly covered with glacial drift. Soils of impeded drainage are widespread, hence the abundance of the alder and plant communities of wet soils. These woods have escaped clearing from the sixteenth century onwards because the valley in which they grow is extremely inaccessible and the pressure of land use has been correspondingly smaller throughout the centuries. They are of particular interest in the study of the alder at a relatively high altitude.

Permits will be necessary for those who wish to undertake research, to collect specimens, or to visit areas away from the rights of way. Applications for permits should be sent to the Regional Officer for North Wales, in Caernarvon.

Coed Gorswen Nature Reserve, lying at the northern end of the Conway Valley on the western side of the river near Rowen, is a good example of a lowland oak wood. The reserve, which covers 33 acres of the woodland and lies within the Snowdonia National Park, has been established under leases with the owners of the land.

The subsoil of Coed Gorswen is a very bouldery glacial drift and probably as a consequence of this it has been woodland for a very long time, perhaps throughout the historical period. The oaks consists of a heterogeneous population of intermediate forms between the sessile and pedunculate oak. As well as oak, other trees present in some quantity include elm, ash and alder. The ground flora is typical of rather base-rich soils, including such species as dog's mercury, sanicle, slender false-brome, common enchanter's night-shade, broad helliborine, skull cap and very locally yellow archangel. Fringing the wood is some interesting fenny ground—no doubt the "gors wen" (white marsh) which gave the wood its name—dominated by purple moor-grass with associates such as quaking grass.

Permits, which will be required to visit parts of the reserve away from the rights of way, to collect specimens of animals or plants, or to undertake research, can be obtained from the Regional Officer for North Wales.

Allt Rhyd-y-groes Nature Reserve is situated in the valley of the Afon Doethie, a tributary of the Towy, about nine miles north of Llandovery in Carmarthenshire. The reserve consists of 46 acres of oak woodland and has been leased to the Nature Conservancy by the Earl of Cawdor. It is hoped that it will ultimately be extended to include other areas of outstanding scientific interest in the locality.

The reserve overlies shales of Silurian age, and extends between 500 and 1,000 ft. on the west side of the steep flanks of the Doethie Valley. The woodlands are dominated by the sessile oak, as is the Coed Rheidol Nature Reserve in Cardiganshire, but here at Allt Rhyd-y-groes a number of the trees are well grown and display a vigour which is not often seen in equivalent woods elsewhere in Wales. The drier, more eroded slopes are clothed in sweet vernal grass together with mosses at the lower levels, and sheep's fescue higher up the slope.

Permits to visit parts of the reserve away from the rights of way, to collect specimens of animals or plants or to undertake research, can be obtained from the Regional Officer for South Wales, The Nature Conservancy, c/o Department of Zoology, University College of Swansea, Singleton Park, Swansea.

Blackcliff and Wyndcliff Forest Nature Reserve. An agreement has recently been reached between the Nature Conservancy and the Forestry Commission on the management of approximately 200 acres of Blackcliff and Wyndcliff Woods, forming part of the Commission's Tintern Forest, Monmouthshire, as a Forest Nature Reserve in the interest of nature conservation and ecological research jointly with those of timber production. The high amenity value of the area, which is close to Tintern Abbey and within the Forest of Dean Forest Park, will be maintained. These woods, situated on the Carboniferous limestone of the Wye Valley, have long been regarded by botanists as being of outstanding scientific interest; they were visited by John Ray in 1662 and by Sir Joseph Banks and John Lightfoot in 1773. The steep slopes are finely wooded with ash, wych elm, beech, small-leaved lime, yew, oak, cherry and whitebeam and service tree, together with a number of shrubs including dogwood, guelder rose and spurge laurel. The ground flora is rich and includes some locally uncommon species: lily of the valley is found there, and white angular Solomon's seal occurs on the cliffs.

Access will be unrestricted, but permits will be required to collect specimens of animals or plants, or to undertake research. Applications for permits should be sent to the Regional Officer for South Wales at the University College of Swansea.

INVESTMENT IN THE COAL, ELECTRICITY AND GAS INDUSTRIES

IN replying for the Government in a debate on fuel and power policy in the House of Commons on February 6, the Parliamentary Secretary to the Ministry of Power, Sir Ian Horobin, said that the oil companies and the Central Electricity Generating Board were considering together whether, within the framework of existing contracts, it would be practicable to postpone the conversion of two more power stations to oil during 1959; even in the changed industrial climate of the past twelve months Sir Ian said it would be wrong and improper to break contract or use pressure to that end. In moving the second reading of the Electricity (Borrowing Powers) Bill on January 20, the Paymaster-General, Mr. R. Maudling, said that the purpose of the Bill was to increase the authorized capital of the industry under the Bill, and the Electricity Council's permitted borrowings would be increased to £2,300 million, those of the North of Scotland Hydroelectric Board to £300 million and of the South of Scotland Electricity Board to £135 million. The total capital investment of the industry envisaged over the next seven years amounted to £2,130 million, of which £1,470 million would be in generation and £660 million in distribution: these figures were for the Electricity Council alone. This plan was based on estimated demand for electricity over the period, including a two-thirds increase in consumption, in which farm uses would be doubled and other commercial use would increase by about 50 per cent, or an annual increase of 6·6 per cent compared with 7·6 per cent in the past seven years. To meet this estimated increased demand of just under 9 million kilowatts, new plants for 12·25 kilowatts would be commissioned. The load factor had improved from 42·7 per cent in 1947 to 46·8 per cent in 1958 compared with a probable maximum of 60 per cent, and the problem of increasing the factor was being tackled with vigour. The cost per kilowatt of increased capacity was now no higher than ten years ago, in spite of the increase in cost of materials and labour. As regards nuclear power, the cost of the Bradwell and Berkeley stations would be about three times that of a coal-fired station, but that of Hinkley Point should be about 2·5 times, and it was now calculated that this would be about £120 a kilowatt. By the nineteen-sixties the nuclear plant should be marginally more economical than conventional plant. There had already been a reduction at the rate of about 3 million tons of coal a year in the amount of oil to be used for power stations in the early nineteen-sixties, and the Government believed that the demand of the power stations for coal would rise throughout the next seven years.

Lord Mills, the Minister of Power, added a few further details in moving the second reading of the Bill in the House of Lords on March 3. Since some of the existing plant will not be fully operated, and because of obsolescence, the net increase in output capacity in England and Wales will be just over 10 million kilowatts, while the South of Scotland Electricity Board expects to commission more than 1 million kilowatts of new plant and the North of Scotland Hydroelectric Board about 460,000. The load factor is expected to increase to 49·2 per cent by 1964–65, and Lord Mills hoped that substantial improvements could be made in the methods of transmission and distribution so as to reduce the need for overhead lines in the countryside. The Boards had very much in mind the need to find means of diminishing the impact of their lines on amenities. Apart from the hydroelectric plant in the north of Scotland, practically all this new plant would be coal-fired or nuclear, and it was estimated that nuclear power could absorb nearly 47 per cent of the £1,100 million which the Central Electricity Board proposed to spend on power station construction. The nuclear power programme for 1964 onwards had not yet been decided, but apart from water-power we intended to rely in the long-term on coal and on nuclear power: less than 4 per cent of the investment in power stations proposed over the next seven years represented oil-fired plant.

These statements form a background to the third White Paper* on capital investment in the coal, electricity and gas industries, which is limited to the years 1957–59. Actual expenditure in 1957 was £434·7 million, compared with £438·9 million and £524·7 million approved for 1958 and 1959, respectively. Of these figures, £240·2 million, £241·3 million and £303·5 million are for the Electricity Council and Boards in the respective years: actual expenditure in 1958–59 is estimated to have been £258·5 million, of which £106·5 million was for conventional power stations and £38·0 million for nuclear power stations. The corresponding figures in the approved 1959–60 programme are £117·5 million and £57·0 million, and payments in respect of the nuclear power stations at Bradwell, Berkeley and Hinkley Point will reach their peak during the year. The North of Scotland Hydroelectric Board's programme of capital expenditure of £10 million on generation for 1959 is mainly for hydroelectric schemes at present in hand, while that of the South of Scotland Electricity Board of £16·2 million on generation in 1959 is almost entirely accounted for by the nuclear power station at Hunterston and the coal-fired station at Kincardine.

BATHYSCAPHE *F.N.R.S.* III

One of the greatest recent advances in methods of deep-sea research is that of direct observation under water by photography, television and the human eye. The latter had already been shown possible before the Second World War by Otis Barton and William Beebe in the cable-dependent bathysphere.

In 1939, Prof. Auguste Piccard and Prof. Max Cosyns gained the support of the Fonds National de la Recherche Scientifique Belge (F.N.R.S.) to build their free-navigating bathyscaphe, but owing to the War its construction was delayed. The first tests were made in December 1948 off Dakar in the vessel which was entitled *F.N.R.S.* II, the Piccard–Cosyns stratosphere balloon being *F.N.R.S.* I. A depth of 1,380 m. was achieved without passengers. Although improvements were needed, the possibilities of the bathyscaphe were proved, and in October 1950 an agreement was signed between the Belgian Fonds National de la Recherche Scientifique, the French Navy, and the French Centre National de la Recherche Scientifique for the construction by the French Navy at Toulon of *F.N.R.S.* III, using the sphere of bathyscaphe *F.N.R.S.* II. This new vessel was put into the water in June 1953 and Capitaine de corvette G. Houot was placed in command with Ingénieur du génie maritime P. Willm to assist. Together they carried out a series of tests ending off Dakar in February 1954 when they reached a depth of 4,050 m.

In May 1954 the French Centre National de la Recherche Scientifique obtained permission from the Navy to equip and use *F.N.R.S.* III for scientific purposes. A management committee was appointed under the stimulating presidency of Prof. Louis Fage. The first dive was made on April 18, 1954, at a position 25 miles south-west of Dakar to a depth of 850 m. with Prof. Th. Monod as the scientist on board; this was quickly followed by a dive to 1,400 m. Thereafter a certain number of dives have been made each year with Commandant Houot on board, accompanied by a qualified naturalist. By the end of 1957, twenty-eight dives had been made to depths between 130 m. and 2,290 m., eighteen of which were deeper than 1,000 m. Eight distinguished and courageous biologists took part. Their names are given here, together with the number of dives each made, because they should be remembered as pioneers of this new era of marine research: Prof. Th. Monod, Dakar (2); Prof. J.-M. Péres, Marseilles (9); J. Picard, Marseilles (4); Prof. Fr. Bernard, Algiers (3); J. Furnestin, Paris (1); Prof. Dubuisson, Liège (1); G. Trégouboff, Villefranche (6); M. Ruivo, Lisbon (1).

Dives were made in the Mediterranean and the Atlantic. *F.N.R.S.* III is equipped with apparatus for recording at any time the depth, temperature and pressure; it has equipment for collecting water samples with contained microplankton; and it has powerful light projectors and automatic cameras. It does not yet possess means for efficient capture of larger planktonic or bottom-living animals, but observations can be supplemented by collections made by the accompanying vessel with pelagic nets and trawls.

A number of individual accounts have already been published, but a general review of the principal results obtained up to the end of 1957 has now been made available*. Since much of the biological information must be obtained by direct observation, it is essential that the accompanying biologist should be experienced, and that he should have a thorough knowledge of the fauna he is to investigate so that he may be able to identify as many organisms as possible. The more dives he makes also the more competent will he become at observing. Given these requirements there is no doubt that the results obtained will be of great value since the depth, temperature and light conditions can be known exactly. Indeed, most interesting information is already forthcoming on the distribution in depth and abundance of some plankton animals. The occurrence of coccolithophores in considerable numbers at great depths has also been established. A noteworthy feature is the abundance of particles in suspension at different depths. It is now known that the subsistence of the bottom sediments is reasonably firm. Numerous small mounds on the sea bottom are common, but prolonged watching has so far revealed no occupants. Unusual habits and movements of deep-sea fish have been observed. The presence of slow currents has been shown by particles drifting along the bottom.

There is no doubt that the value of the bathyscaphe as a tool in marine research has been proved by French scientists, to whom all honour is due; and as a result new models to attempt greater depths are on the way.

ALFVÉN WAVES IN A GAS DISCHARGE

By D. F. JEPHCOTT*

Atomic Energy Research Establishment, Harwell, Berks

In 1942 Alfvén[1,2] predicted the possible existence of magnetohydrodynamic waves, which may be regarded in the simplest case as transverse oscillations of magnetic field lines carrying with them a surrounding inviscid perfectly conducting fluid.

The velocity of propagation is given by:

$$V^2 = \frac{\mu H^2}{4\pi n M}$$

where H = magnetic field intensity; n = number of particles/cm.^{3}; M = mass of particle.

Alfvén's theory strictly applies only to waves in an incompressible fluid, but it can be extended to a compressible fluid (for example, an ionized gas) for the case of waves of small amplitude. A further restriction is that the frequency should be small compared with the ion cyclotron frequency[3].

Previous experimental work has been carried out in liquid conductors[4-6], and standing Alfvén waves have been reported in some gas discharges[7,8].

Our experiments have been carried out using toroidal gas discharges of 10 k.amp., and 200 µsec. duration, in monatomic gases at initial pressures of about 100µ, and with axial (B_z) fields in the range 3–14 k.gauss. Under these conditions, the current density was nearly constant across the area of the torus (except close to the walls) and the discharge sufficiently quiescent for satisfactory signals to be obtained from magnetic probes.

Fig. 1 illustrates the method used for exciting the waves and measuring their velocity.

When the gas current had reached its peak value, the condenser C was discharged via the spark gap S through the exciter conductors A and B, which were close to the outer wall of the torus. The condenser circuit oscillated at 260 kc./s., imposing perpendicular components on the main field, and resulting in torsional oscillations about the circular axis of the torus.

Oscillations of the order of 10 gauss in amplitude were picked up by the magnetic probe 2 and were found to be delayed relative to the signal from probe 1 which recorded the direct exciting field. No oscillations were observed with $B_z = 0$, and the amplitudes always increased with B_z over the working range. Velocities were calculated after a small correction had been made for the measured time-lag of the perturbing field at D ($d = 0$) in the plasma, relative to the direct vacuum field of the conductors.

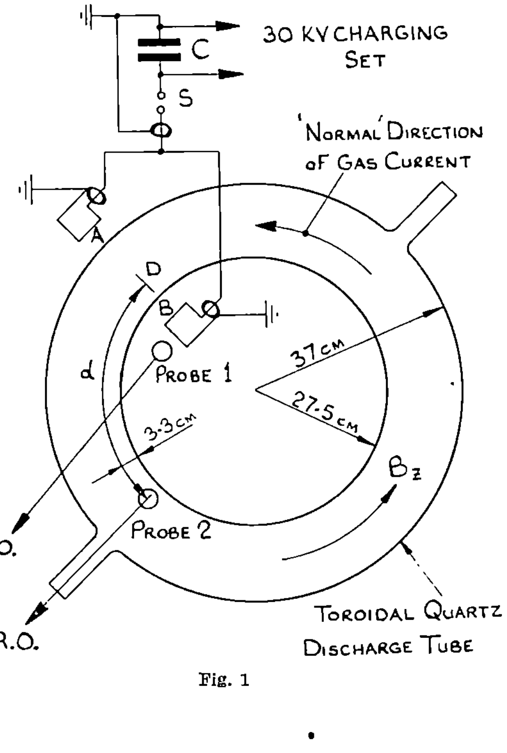

Fig. 1

---

* On attachment from Hawker Siddeley Nuclear Power Co.

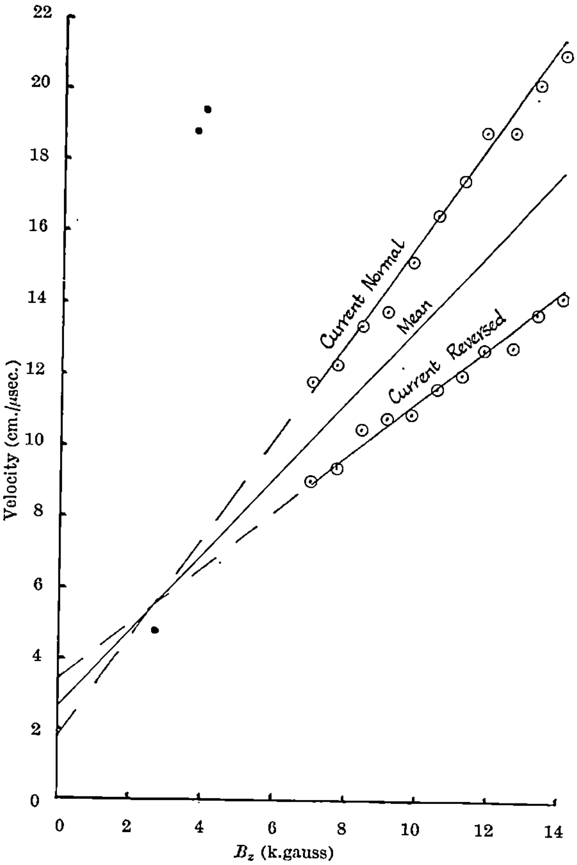

Fig. 2. Argon, 70μ; 10 k.amp.; d = 44 cm.

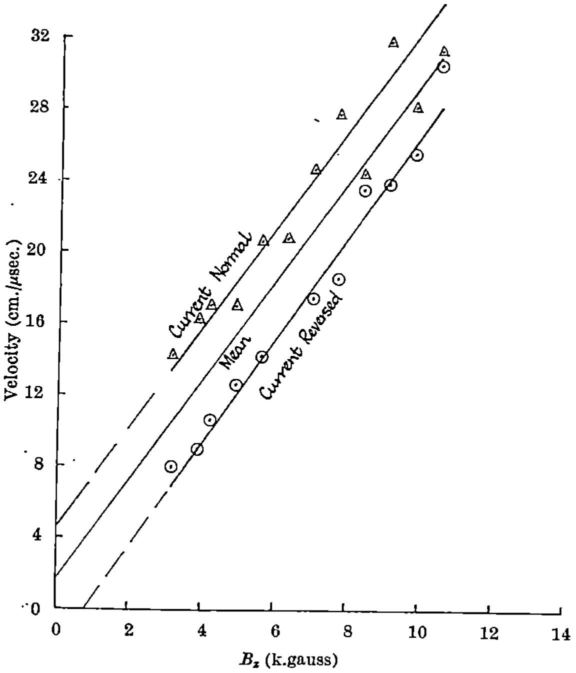

Fig. 3. Helium, 130μ; 10 k.amp.; d = 44 cm.

The velocities have been measured over a range of B_z values, keeping the gas current and initial pressure constant. For argon and xenon, the upper limit to B_z was set by the maximum field available, while in helium the signals became distorted at 10 k.gauss. The lower limit on B_z was set by the value below which the signals were too small to be measured accurately. In xenon, no readable signals were observed with d = 44 cm., and with d = 20 cm. the velocity increased with B_z only for fields greater than 10 k.gauss.

The exciter frequency was well below the ion cyclotron frequency in helium, just below it in argon, and above it in xenon (which probably accounts for the results obtained in xenon).

Velocities were measured with the gas current 'normal' (that is, flowing in the same direction as the waves being propagated from the exciter along the shorter arc to the gas probe) and 'reversed'. In all cases, the measured velocities with gas current normal were found to be higher than with the current reversed, the discrepancy increasing with B_z in the case of argon (see Figs. 2 and 3).

A theoretical treatment[9], involving the interaction of the axial current with the perturbed field, shows that some dependence of the velocity on current direction is to be expected, but at present the numerical agreement with experimental results is correct only in order of magnitude.

For the present, we assume the wave velocity to be given by the mean of the velocities measured with the current normal and current reversed.

The positive intercepts on the velocity axes in Figs. 2 and 3 may be due to two possible causes:

(1) No correction has been made for any increase in wave velocity due to damping.

(2) Since the axial magnetic field along any arc is inversely proportional to the radius of the arc, while d is directly proportional to the radius, waves being propagated close to the outer wall tend to lag behind those near the inner wall. Hence, if there is any coupling between waves travelling along arcs of different radii, the wave velocity may be some mean value of the local Alfvén speeds.

Table 1 gives a summary of the results obtained so far in helium and argon. From the Alfvén velocity expression, the ion density has been calculated as given by the slope of the graph of mean velocity against B_z. For argon, the ion density has also been checked with a Langmuir double probe, and the two values for ion density thus obtained show satisfactory agreement. The double probe signals also indicated no changes in ion density due to the passage of the

Table 1

Gas	Gas current (k.amp.)	B_z range (k.gauss)	Range of Alfvén wave-lengths (cm.)	Ion cyclotron frequency range (kc./s.)	Exciter frequency (kc./s.)	Particle density before discharge (No./cm.^{3})	Ion density from wave velocity (No./cm.^{3})	Ion density from double probe (No./cm.^{3})	Electron temperature from double probe (deg. K.)
Helium	10	3–10·5	40–120	$1·14 \times 10^3$–$4·0 \times 10^3$	260	$4·6 \times 10^{15}$	$1·51 \times 10^{15}$	—	—
Argon	10	7–14	40–70	270–540	260	$2·5 \times 10^{15}$	$1·04 \times 10^{15}$	$1·14 \times 10^{15}$	$4·7 \times 10^4$

wave train, and little dependence of ion density on B_z or on the current direction.

The measured velocity of the waves as a function of B_z in different gases shows agreement with theory (except in the case of xenon at low B_z, where the ion cyclotron frequency is appreciably lower than the wave frequency). Hence, in spite of the preliminary nature of the experimental results, there seems little doubt that the oscillations observed were due to the passage of Alfvén waves.

It may be possible, using Alfvén wave velocity measurements of this kind, to determine the ion density of plasmas in magnetic fields, and from measurements of the damping to find the degree of ionization, the electron temperature or the ion temperature, depending on the dominant dissipative process.

I am indebted to Dr. G. Francis and other members of the Atomic Energy Research Establishment, Harwell staff, with whom I have had useful discussions, and particularly to Dr. R. J. Bickerton, who suggested this work, for his help and advice.

CANALIZATION OF DEVELOPMENT AND GENETIC ASSIMILATION OF ACQUIRED CHARACTERS

By Prof. C. H. WADDINGTON, C.B.E., F.R.S.
Institute of Animal Genetics, Edinburgh 9

Genetic Control of the Canalization of Development

In multi-cellular organisms the development of tissues and organs commonly exhibits a balance between flexibility and inflexibility; while a sufficient external stress will cause development to divergence and reach some unusual end-result, there are counteracting tendencies to attain the normal adult condition even in the face of disturbing influences. This condition, which has been referred to as the 'canalization of development'[1], must be regarded as a result of the complex interactions between the numerous gene-controlled processes by which development is brought about. It should therefore be possible to modify the degree of flexibility–inflexibility by selection of appropriate genotypes. There has as yet been little direct evidence on this point, although it has been shown that there is some control by the genotype over the repeatability of development (the inverse of developmental 'noise')[2].

Many mutant phenotypes, in *Drosophila* and other organisms, are notoriously sensitive to environmental influences. Experiments were carried out with, among other phenotypes, that of Bar in *D. melanogaster*. The number of facets in the eye is much reduced, but is larger at low temperatures than at high. The offspring of a number of pair matings were divided into two lots, one of which was grown at 25° C., the other at 18° C. Selection was made by breeding from the families with the smallest differences between the family means at the two temperatures. After only five generations, the difference was reduced from about 100 to around 12 (Table 1). The lowering of the difference has involved both an increase in the size of the eye at the high, and a reduction of its size at the low, temperatures; clearly the selected genotypes are much more inflexible (better canalized) against temperature variations. There was no accompanying change in the 'noisiness' of development, as judged by the differences between the logarithms of facet numbers on the two sides of the individual flies.

Table 1. Bar. Facet Numbers in Females in Unselected Controls, and in three Families resulting from Selection

	No. of families	Average family mean, at 18° C., and S.E.	Average family mean, at 25° C., and S.E.	Difference, family means 18° C. and 25° C.
Unselected	9	156·25±4·81	55·46±0·81	100·80±4·52
Selected 6*a*	8	106·02±1·17	96·52±1·67	14·50±2·29
Selected 6*b*	7	100·76±1·38	95·30±1·70	5·46±1·98
Selected 6*c*	8	111·39±1·72	98·48±2·67	12·92±3·05

Genetic Assimilation of an Adaptive Acquired Character

It has been shown that if a strain of organisms is selected for several generations for increased readiness to become developmentally modified in some specific manner in response to an environmental stress, the later generations may exhibit the modification even in the absence of the stress which was initially required to produce it; and it has been argued that this process of 'genetic assimilation' may play an important part in the evolution of adaptive characters[1]. The experiments which have been described so far have dealt with characters which (*a*) would not be adaptive in Nature, and (*b*) the production of which involved threshold phenomena. Both these limitations have been removed in a recent experiment.

Three strains of *Drosophila melanogaster* (Oregon *K* wild-type, sp^2bs^2 and $al\ b\ c\ sp^2$) were grown on normal medium to which sodium chloride had been added in sufficient quantities to lead to considerable mortality (> 60 per cent) of the larvæ. Thus, stringent natural selection occurred; and by increasing the salt concentration in later generations, the intensity of selection was maintained at a roughly constant level for twenty-one generations. At that stage counted numbers of eggs were set up on media of various salt concentrations, and the unselected stocks from which the experiment had started were tested simultaneously. The percentage of survivors was ascertained on each medium, and measurements were also made of the area of the anal papillæ, since it has been suggested by Gloor and Chen[3] that these organs are concerned with the osmotic regulation of the larva, although their exact function is not well understood.

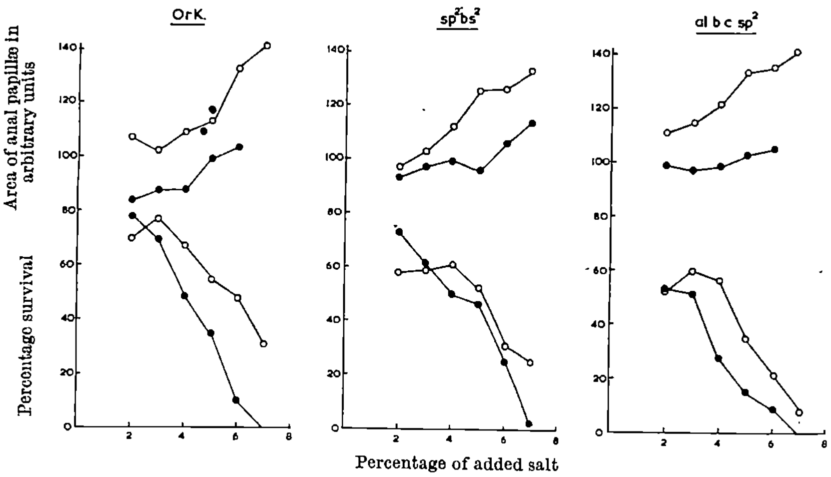

Fig. 1. Percentage survival (below) and size of anal papillæ (above) in selected and unselected strains in various concentrations of salt.

Unselected, ●—●; selected, ○—○

Measurements of the papilla area were made on young prepupæ to minimize alterations due to the contractility of the larva.

As can be seen from the lower graphs in Fig. 1, the selected strains survive better than the unselected at the high salt concentrations, which range up to 7 per cent—twice as high as sea water. From the upper curves, it is clear that the area of the anal papillæ increases in higher salt concentrations. Two points are noticeable: (1) the size of the papilla in the selected strains is greater at all concentrations than in the unselected; (2) the steepness of the curve is increased in the selected strains. The first point indicates that some genetic assimilation has occurred; the selected strains in a relatively normal environment (low salt) have anal papillæ of a size which the unselected strains only attain in response to the stress of added salt. The second point is evidence that the selection has improved the adaptability of the animals, rendering them more responsive to salt concentration. The first point, however, shows that their adaptability is still limited, and it is clearly because of this limitation that some degree of genetic assimilation has occurred.

CELL GROWTH AND THE DEVELOPMENT OF TUMOURS

By ANNA KANE LAIRD and A. D. BARTON

Division of Biological and Medical Research, Argonne National Laboratory, Lemont, Illinois

IN the course of biochemical studies[1,2] of liver cell fractions carried out during the induction of liver tumours by known carcinogens, a fairly regular pattern of cell proliferation became apparent. It is the purpose of the present article to relate this pattern to earlier observations by other investigators, and to discuss various implications concerning the carcinogenic process.

In studies in which liver tumours were induced in rats by continuous administration of diets containing 2-acetylaminofluorene[3] or 4-dimethylaminoazobenzene[4], others have shown that grossly recognizable tumours are not obtained until 200 or more days after the animals are placed on the carcinogenic diet. These workers have also shown that it is not necessary that the administration of the carcinogen be continued until tumours are visible; it must be continued only through a certain critical period. For example, if the animals are returned to a normal diet after only 25–30 days exposure to 2-acetylaminofluorene or 4-dimethylaminoazobenzene, few if any will develop tumours; if they are exposed for a total of 50–75 days, a large proportion of the rats will develop tumours, and the number is not greatly increased by continuing the administration beyond this time. This finding suggests two conclusions concerning the neoplastic transformation that ultimately leads to the production of a tumour: (1) malignant cells are not produced unless administration of the carcinogen is continued beyond the time required to produce a significant threshold effect, the nature of which is undefined; (2) when the transformation does occur, it takes place within a relatively short period of time.

In the present experiments, male rats were fed continuously a diet containing 2-acetylaminofluorene. Two such experiments were carried out, using rats of different strains and different initial body-weights (details are given in the legend to Fig. 2). The changes in weights of body and liver obtained in the second experiment are shown in Fig. 1 (the corresponding results in the first experiment were similar). Within a few days of the inception of the carcinogenic treat-

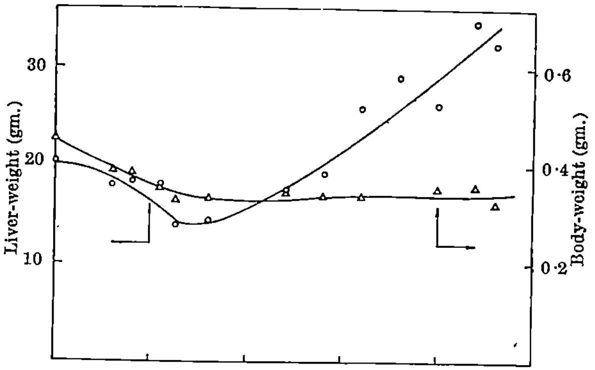

Fig. 1. Changes in weights of liver and body of rats during administration of 2-acetylaminofluorene in the diet, at a concentration of 0·06 per cent

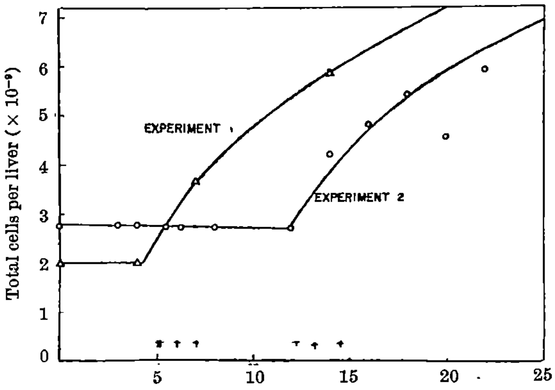

Fig. 2. Changes in the total number of liver cells during administration of 2-acetylaminofluorene, in two different experiments. In Exp. 1, rats of the Holtzman strain, weighing 180–200 gm. at the start of the experiment, were fed a grain diet mixed in the laboratory (ref. 2); the food contained 2-acetylaminofluorene in an initial concentration of 0·05 per cent, which was later reduced to 0·04 per cent. In Exp. 2, rats of the Sprague–Dawley strain, weighing 350–450 gm., were fed a ground 'Purina' diet containing 2-acetylaminofluorene in a concentration of 0·06 per cent. The crosses at the bottom of the graph represent spontaneous deaths of individual rats; the left group of four occurred in Exp. 1, and the right group of three occurred in Exp. 2

ment, the weight of the body fell, until it levelled off at a value distinctly below the initial weight (and even further below the weight of normal controls the weight of which had been increasing in the meantime). In contrast to the fall in weight of the body, that of the liver increased continuously to well above the control values, following a relatively brief initial fall.

The total number of cells in such livers may be determined by introducing appropriate dilutions of a homogenate into a hæmacytometer and counting the cell nuclei present. Since each homogenate is prepared from fresh liver pulp, from which a major part of the connective tissue is removed by use of a tissue press, the cells counted are mainly parenchymal. The changes in the total number of cells per liver are shown in Fig. 2. The course of the changes ran closely parallel in the two experiments. After a period in which no net change in the average number of liver cells was observed, a rapid increase occurred, the rate of which slowed as the carcinogenic period progressed. The increase in number of cells began later in the experiment in which the larger rats were used; the reason for this difference is not understood, but is under investigation. The crosses at the bottom of Fig. 2 represent the spontaneous deaths observed; those on the left occurred in Exp. 1, and those on the right in Exp. 2. It is evident that in each experiment a critical period occurred, at which time some of the animals died and the number of liver cells in the survivors started to increase rapidly. The limitation of spontaneous deaths to the brief period when active cell proliferation was first beginning suggests that a crisis was precipitated by a decrease in the functional capacity of the liver which made a rapid proliferation of liver cells necessary to save the animal from death. The critical period thus defined in physiological terms apparently corresponds in timing to the critical period through which administration of the carcinogen must be continued to obtain a high incidence of animals with tumours.

If such a critical period occurs during carcinogenesis in other organs, it would not necessarily be accompanied by an increase in mortality, if the target organ were one not required for survival, or if destruction were local in the organ (experimental skin carcinogenesis, for example). Survivors who have developed leukæmia since the atom bomb explosions in Hiroshima and Nagasaki quite generally showed signs of severe damage to the blood-forming organs soon after the exposure[5], and, of course, many of the individuals with severe damage of this sort died at that time. Thus development of leukæmia may be similar to hepatic carcinogenesis, to the extent that in both cases a tissue or organ essential to survival is damaged so severely that its total functional capacity is greatly reduced, with the result that some of the victims succumb immediately whereas others enter a period of active repair, characterized by rapid proliferation of the surviving cells in the damaged tissue. In some cases during this period of active proliferation in damaged tissue, malignant cells are produced, the presence of which is revealed only after sufficient time has elapsed to permit their multiplication to produce recognizable tumours.

When instead of 2-acetylaminofluorene, rats were fed 3′-methyl-4-dimethylaminoazobenzene, an azo dye and a well-known hepatic carcinogen, the changes in number of cells shown in Fig. 3 were observed. The time-scale is much expanded compared with Fig. 2, and the curve therefore constitutes essentially a magnification of the early changes seen in the two curves of Fig. 2. Although the carcinogen used in this experiment differs from 2-acetylaminofluorene both chemically and in its pathological effects, it produced very similar changes in the total number of liver cells: an initial period without change in number of cells, followed by an abrupt increase in the number of liver cells. In this case, the number of cells in the liver increased by 50 per cent in two days.

Since the tumour cells occur in discrete nodules which grow separately from the rest of the tissue, and since numerous mitotic figures are found within the tumour mass, it seems likely that growth of the tumour occurs not by continued transformation of liver cells into tumour cells, but rather by proliferation of the tumour cells themselves. It is probable that each discrete tumour arises from one malignant cell. If we consider the actual number of cells involved in the sudden 50 per cent increase noted in the experiment with 3′-methyl-4-dimethylaminoazobenzene described in the preceding paragraph, we find that 10^9 new cells were formed in 48 hr. If this is the case, then to produce 100 tumours, a malignant change would have to occur in only one cell per ten million new cells formed. Even if only 1 per cent of the cells undergoing a malignant transformation

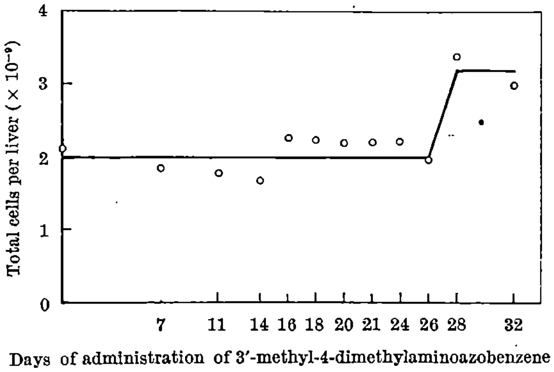

Fig. 3. Changes in the total number of liver cells during administration of 3′-methyl-4-dimethylaminoazobenzene. Note that the time-scale is much expanded compared to Figs. 1 and 2

Table 1

Given : Weight of tumour-bearing livers, approx. 35 gm.
Weight of tumours, approx. 4 gm.
Cell count, per gm. liver, approx. 200 × 10^6
Cell count, per gm. tumour, approx. 450 × 10^6
Then : Tumour-bearing liver contains about 8,000 × 10^6 cells, of which about 1,800 × 10^6 cells are tumour cells and about 6,200 × 10^6 cells are liver cells.

If 4 gm. of tumour constitute :
(1) All one tumour mass, all from one cell : then 31 cell generations would be required.
(2) 4 separate tumours, 1 gm. each, each from one cell : then 29 cell generations would be required.
(3) 4,000 separate tumours, each 1 mgm., each from one cell : then 19 cell generations would be required.

But the liver started with 2,000 × 10^6 cells, and contained 6,200 × 10^6 at the end of the experiment : this would require less than 2 cell generations.

survived to produce a tumour, the incidence of malignant change in the above example would still be only one cell in one hundred thousand. In other words, even during continued exposure of liver cells to a carcinogen, the carcinogenic change is probably a very rare event.

In Table 1 are given the data necessary for calculating approximately the number of cell generations required to produce the tumours observed, and also the number of cell generations occurring in the surrounding liver tissue, assuming that all daughter cells survive in both cases. The figures given for weights of liver and tumour are representative of our findings with 2-acetylaminofluorene. The tumour data have been calculated for three conditions : (1) the tumour tissue occurs in the form of a single tumour mass ; (2) the tumour tissue is found as several 1-gm. tumours ; and (3) the tumour tissue occurs in the form of several thousand 1-mgm. tumours. The condition observed in practice most closely approximates the second case, with tumour nodules ranging in number from less than 10 to about 100. The data in Table 1 show that during the period in which the tumour cells have passed through 20–30 cell generations, the surrounding parenchymal liver tissue has passed through less than two cell generations on the average. Without radioautography, it is difficult to know whether such average increases in cell number are due to a few divisions of many cells, or to many divisions of a few cells. However, if the data of Fig. 3, obtained with 3′-methyl-4-dimethylaminoazobenzene, can be carried over to the experiments with 2-acetylaminofluorene, then the increase in cell number observed early in the experiment is due principally to a few divisions of a large number of liver cells, since the 50 per cent increase in number of cells observed in that experiment occurred within too brief a period of time to permit many cycles of cell division to be repeated. It might be pointed out here that in the very rapid cell multiplication that occurs in liver regenerating after partial hepatectomy, the total increase in number of cells also amounts to less than two cell generations on the average, and since such an increase in cell number is preceded by an increase of more than 50 per cent[6] in the average content of deoxyribonucleic acid per nucleus, it is probable that here, too, the increase in mass of liver is due to a few divisions of many cells.

If at first less than one cell in a million is producing progeny that would eventually yield tumours, then the rapid initial rise in the total number of cells in the livers must be due primarily to multiplication of liver cells rather than potential tumour cells. If this is true, then much of the mitotic activity of the liver cells is already completed soon after the initial burst becomes evident. Comparison with the earlier data[3,4] suggests that this initial burst of cell division is the essential feature of the critical period through which the administration of the carcinogen must be continued in order to obtain a high incidence of animals with tumours. Unless the administration of the carcinogen is maintained until the burst of cell division is produced, few, if any, malignant cells are produced. Once this burst of cell division is elicited, sufficient malignant cells are produced to make further administration of the carcinogen unnecessary. Since the critical period is so short, it is evident that the change from a normal liver cell to a malignant cell can occur within a short time, possibly within one or two cell generations. This suggests that the change essential to malignancy is sudden and complete, rather than continuous over many cell generations. Further important changes in the direction of increasing anaplasia and independence of normal growth-control mechanisms are known to occur[7], but we are considering here only the initial, essential step.

This work was performed under the auspices of the U.S. Atomic Energy Commission.

GEL FILTRATION: A METHOD FOR DESALTING AND GROUP SEPARATION

By Dr. JERKER PORATH
Institute of Biochemistry,
University of Uppsala

AND

Dr. PER FLODIN
Research Laboratories, Pharmacia,
Uppsala

We wish to report a simple and rapid method for the fractionation of water-soluble substances. The method is based on a column procedure similar to chromatography in which the stationary phase is comprised of a new type of gel. These gels consist of hydrophilic chains which are cross-linked. They are devoid of ionic groups, the polar character being almost entirely due to the high content of hydroxyl groups. While water-insoluble, the gels are nevertheless capable of considerable swelling. The fractionation depends primarily on differences in molecular size although phenomena have been observed which indicate the influence of other factors.

The idea that gels might be used for the zone separation of substances differing in molecular size is not a new one. Synge and Tiselius[1], for example, have

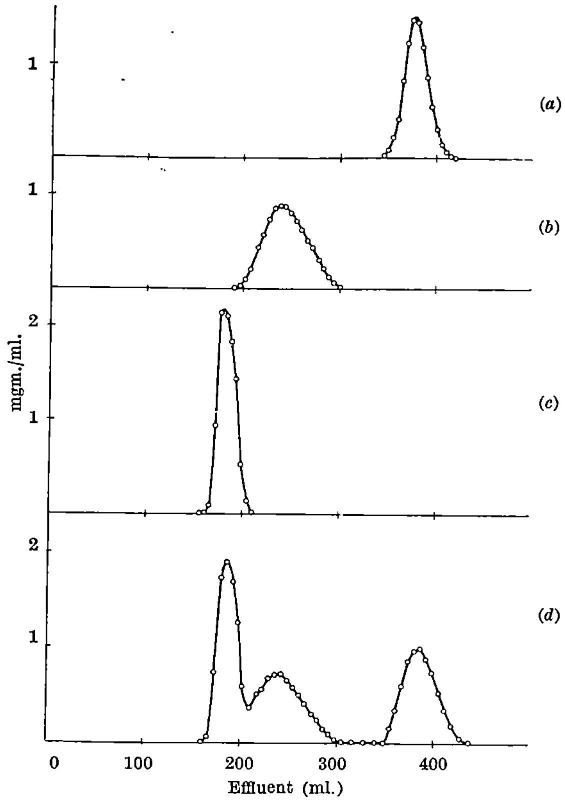

Fig. 1. The diagrams illustrate 'molecular sieving'. In experiments *a*, *b* and *c*, 5 ml. of 1 per cent aqueous solutions of glucose and dextran fractions of $\overline{M}_n$ 1,000 and 20,000, respectively, were filtered through a dextran gel column of the size 4·0 × 36·5 cm. Diagram 1*d* shows the result of a similar experiment with a mixture of the substances mentioned

suggested such a method, based on the effect of friction during electro-osmotic migration through gels. In a homologous series of uncharged substances the friction may be expected to rise with increasing molecular weight. Thus the higher homologues should be retarded more strongly than the lower ones. This is, in fact, the case as was experimentally confirmed by Mould and Synge[2].

On filtration through a bed of starch particles, high and low molecular weight substances also behave differently. In this case, however, it is the lower molecular weight substances which are retarded. We frequently encountered this type of phenomenon when using starch as a supporting medium in zone electrophoresis[3]. It appears likely that the cause of this behaviour is a restricted diffusion of the kind observed by Biget[4]. The restriction is related to the effect of friction observed when solutes are electro-osmotically transported through gels.

Lathe and Ruthven's meticulous and thorough investigation[5] gives a good conception of the possibilities which are inherent in starch filtration. However, starch itself has several undesirable properties. Among these are instability, poorly defined composition and the high resistance to flow of starch columns. Together, these properties have caused the method to be of little practical importance so far.

The above disadvantages seem to be eliminated in the case of certain synthetic gels such as dextran gel. The latter is a material originally synthesized in an attempt to obtain an ideal convection depressor[6] for preparative zone electrophoresis. It is prepared by cross-linking dextran in such a way that the polysaccharide chains form a macromolecular network of great stability. A bed of particulate water-swollen dextran gel has very interesting properties. Aqueous solutions filter rapidly through it at ordinary pressures, and no significant quantity of the gel material is dissolved whether in alkaline, neutral or acid medium. Macromolecules are completely excluded from the gel phase and migrate without retention in the interstitial fluid. However, substances of low or intermediate molecular weight penetrate the gel particles to an extent which is in most cases determined by their molecular dimensions and the degree of cross-linkage of the gel. The separating ability of columns packed with dextran gels is based on these facts.

We have studied dextran gels ('Sephadex' obtained from Pharmacia, Uppsala, Sweden) with varying degrees of cross-linkage graded on the basis of water regain[8], and also other hydrophilic gels derived, for example, from starch and polyvinyl alcohol. Like dextran gels, the latter are chemically stable and as a rule have satisfactory mechanical properties. Moreover their separation properties may be varied within wide limits. More detailed reports will be published later. A few simple examples of the use of the method will be given here.

Some experiments with dextran fractions[7] and glucose are shown in Fig. 1. A glass tube with an inner diameter of 4·0 cm. was packed with 100 gm. of dextran gel suspended in distilled water. The final height of the bed was 36·5 cm. The particle size of the dried form of the gel was between 100 and 200 mesh and its water regain was 2·5 gm. per gm. of dry weight[8]. A filter paper was placed above the flat surface of the bed to prevent disturbances. The test solution was applied and when it had completely entered the bed the column was washed with distilled water at a constant rate of 110 ml./hr. The carbohydrate content was determined using the anthrone method. The recoveries in experiments 1*a*, 1*b*, 1c and 1*d* were 103, 95, 101 and 97 per cent, respectively. The elution volume of the substances and their distribution are independent of whether the substances are filtered through the columns singly or together. The oligosaccharide fraction has a wider distribution than the other substances due to poly-

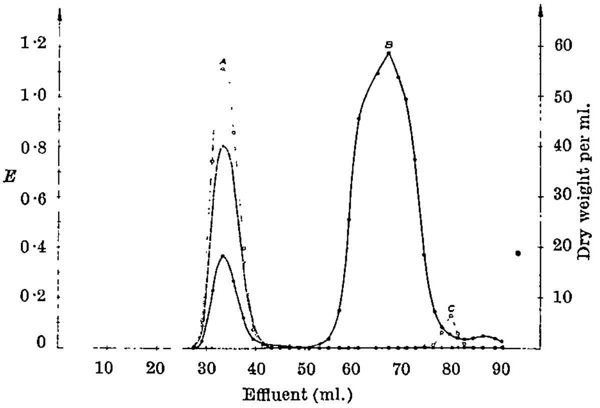

Fig. 2. Diagram showing the separation of ammonium sulphate from serum proteins as obtained after filtration of the solution of the mixture through a dextran gel column (2·5 × 17·5 cm.). Fractions (2 ml. each) were collected and analysed by the method of Folin–Lowry (0·01 ml. aliquots, — × —) and by ultra-violet light absorption at 280 mμ (— ○ —). The weight distribution of the substances in the effluent (— ● —) was determined by weighing 1-ml. aliquots after evaporation *in vacuo*

dispersity. On filtration it is fractionated, and molecular weight determinations of the material from different parts of the peak indicate that the higher homologues are located at the beginning of the peak.

An experiment with serum proteins performed in order to demonstrate desalting is shown in Fig. 2. 5 ml. of a saturated ammonium sulphate solution was added to 5 ml. of fresh human serum and the precipitate was removed by centrifugation. 3 ml. of the supernatant was applied to the top of a bed (2·5 × 17·5 cm.) of the same type of dextran gel as in the previous experiment. The substances were eluted with distilled water at a constant rate of 25 ml./hr. A qualitative analysis for sulphate ions in peak *A* was negative, showing that the proteins had been freed effectively from salt. No proteins could be demonstrated in peak *B*, which contains the entire amount of ammonium sulphate. Peak *C* contains a low molecular weight substance with an absorption maximum at 292 mμ. The yield of material absorbing in ultra-violet at 280 mμ was 102 per cent, that is, it was quantitative within the limits of error.

The result of a gel filtration is often similar to that obtained by dialysis. The unavoidable dilution is naturally a disadvantage but it may be kept within reasonable limits by a suitable choice of experimental conditions. It should be mentioned that the rate of elution and the concentration of solutes can be varied greatly without causing a serious spreading of the zones or altering the position of the peaks. It is necessary in each problem of separation to compromise with respect to those factors which condition the separation efficiency and the rate of elution.

As a desalting method gel filtration presents many advantages relative to dialysis. For example, we have never observed complications corresponding to the clogging of dialysis membranes. The method is especially suited for changing a protein solution from one buffer system to another, a step which is often necessary prior to ion exchange chromatography and electrophoresis.

Gel filtration may be performed with great rapidity and nevertheless causes the complete separation of two or more substances or classes of substances if the differences in molecular size are sufficient. The scale of a procedure such as the desalting of a protein solution may be increased upwards without difficulty so that considerable quantities may be handled.

Since after each complete operation the gel is automatically regenerated, gel filtration is well suited for cyclic purification procedures.

OCCURRENCE OF 'ESTER-LIKE' LINKAGES IN COLLAGEN

By PAUL M. GALLOP, PROF. SAM SEIFTER and EDWARD MEILMAN

Department of Medicine, Long Island Jewish Hospital, New Hyde Park,
and Department of Biochemistry, Albert Einstein College of Medicine,
Yeshiva University, New York

MANY investigators have considered the possibility that primary linkages other than peptide or iminopeptide bonds contribute to the stability of the collagen structure. Thus, Gustavson[1] postulated the existence of ester linkages between the hydroxy groups of the abundant hydroxyamino-acid residues of collagen and the carboxyl groups of terminal residues or of dicarboxylic acid residues elsewhere in the protein. Ames[2] discussed the possible occurrence of an imide cross-linking bond of the *R*.C = O.NH.C = O.*R′* type. In Table 1 are listed some of the primary linkages other than peptide which are possible for collagen. Except for the diester compounds, linkages to carbohydrates have not been included, since the small amount of carbohydrate found in purified collagens could not account for the extent of the hydroxylamine reaction as described here. Except for the side-chain amide and guanidine groups, cleavage of the linkages listed in Table 1 could result in significant decreases in the molecular weight of collagen, and, except for the additional case of interchain peptide bonds, in the production of defined polypeptide units or the separation of individual chains. The presence of acid anhydride bonds to account for the experimental findings is not likely when one considers the conditions under which commercial gelatins are prepared.

It is known that esters may be differentiated from amides or peptides because of their much faster rates of reaction with hydroxylamine at *p*H values of 8–11, and that imides of the type shown in Table 1 may be as reactive as esters. Williams *et al.*[3] showed that certain γ-glutamyl peptides were sensitive to treatment with aqueous hydroxylamine, and Braunitzer[4] claimed that a cyclic iminopeptide linking the β-carboxyl group of an aspartic acid residue and the imino group of a proline residue was cleaved by relatively mild treatment with hydroxylamine. The latter observation led Braunitzer to conclude that an N-terminal proline group of tobacco mosaic virus protein is masked by such a combination, a view which Narita[5] could not confirm.

In the experiments described here, at least three types of gelatin were used: commercial acid- and base-processed gelatins, and gelatins prepared from calf-skin and carp swim-bladder procollagens by mild heating in water or by denaturation with 6 *M* urea. Treatment with hydroxylamine was performed either at room temperature or at 40° C.; in the former case 6 *M* urea was present during the reaction to prevent gelation. Solutions of gelatin containing 2–4 per cent protein were mixed with equal volumes of 2 *M* hydroxylamine hydrochloride solution previously adjusted to *p*H of approximately 10 with sodium hydroxide. In kinetic studies, aliquots were

Table 1. POSSIBLE HYDROXYLAMINE-SENSITIVE BONDS IN COLLAGEN

Type linkage	Structure	Residues which may be involved*
Side-chain amide	$R.CO.NH_2$	$GluNH_2$ or $AspNH_2$
Inter-chain imide	$R.CO.NH.CO.R'$	$GluNH_2$ and Asp or $AspNH_2$ and Glu
Side-chain guanidyl group	$R.NH.C(:NH)NH_2$	Arg
Inter-chain acyl-guanidine link	$R.NH.C(:NH)NH.CO.R'$	Arg and Asp or Arg and Glu
Inter-chain ε-lysyl peptide	$R.CO.NH.CH_2.R'$	Lys and Asp or Lys and Glu
Inter-chain ester	$R.CO.O.CH_2R'$	Ser, Thr or HyLys with Asp/or Glu
Inter-chain ester with HyPro		HyPro with Asp or Glu
Oxazoline from inter-chain ester with hydroxy-lysine		HyLys with Asp or Glu
Inter-chain di-ester with carbohydrate		Carbohydrate with Asp and/or Glu

* The aspartyl and glutamyl residues are conceived of as being linked by means of their β- and γ-carboxyl groups, respectively.

removed at various times and added to 10 *N* hydrochloric acid, bringing them to *p*H 4 in order to stop the reaction. The samples were then dialysed exhaustively against distilled water to remove all free hydroxylamine. Simultaneously with the above reaction, a control mixture of gelatin, containing no hydroxylamine, was maintained at *p*H 10, sampled at intervals, and the aliquots dialysed as above.

The following determinations were then made: protein by a modification of the Kjeldahl method[6] and by the procedure of Lowry *et al.*[7]; N-terminal proline by the method of Piez *et al.*[8], in which terminal proline yields a diminished fraction of the colour given by free proline[9]; amino-groups by the ninhydrin method of Rosen[10]; and amide by the amount of alkali-distillable ammonia produced after hydrolysis with 1 *N* hydrochloric acid for 1 hr. Hydroxamides were measured by three independent spectrophotometric procedures: the classical determination of the magenta complex formed with iron salts such as ferric perchlorate; the quantitation of nitrite produced by oxidation with iodine[11]; and by a method developed in these laboratories, soon to be published, in which hydroxylamine, liberated from hydroxamides by hydrolysis with 1 *N* hydrochloric acid for 3 hr., reacts with indole to yield a coloured product. In addition to these analyses, the protein samples were diluted with equal parts of 1·8 per cent sodium chloride, and studied in a Spinco model *E* analytical ultracentrifuge at 59,780 r.p.m. at 40° C.

With all gelatins studied, the results show that alkaline hydroxylamine causes both a fast and a slow reaction, each characterized by the formation of protein-bound hydroxamide. The fast reaction, which is nearly complete in about 90 min. at 40° C. or in 3 hr. at room temperature, results in a decrease of molecular weight of the protein to a definite end-point of about 20,000. The sedimentation constant changes from the original value of about 3·3 S. for the α-component to a value of about 1·9 S. Fig. 1 shows sedimentation patterns for fish and calf parent gelatins before and after treatment with hydroxylamine, and clearly demonstrates the conversion of both the α- and β-components to the units of lesser molecular weight. During the course of the fast reaction there is no increase in free amino-groups to indicate the splitting of peptide bonds, nor can N-terminal proline be detected. Only late in the course of the fast reaction can one begin to measure a decrease in the number of amide groups; however, when the reaction is allowed to continue beyond this time, a gradual destruction of amide groups and even some cleavage of peptide bonds occur, characteristic of the second or slow phase of hydroxylamine activity.

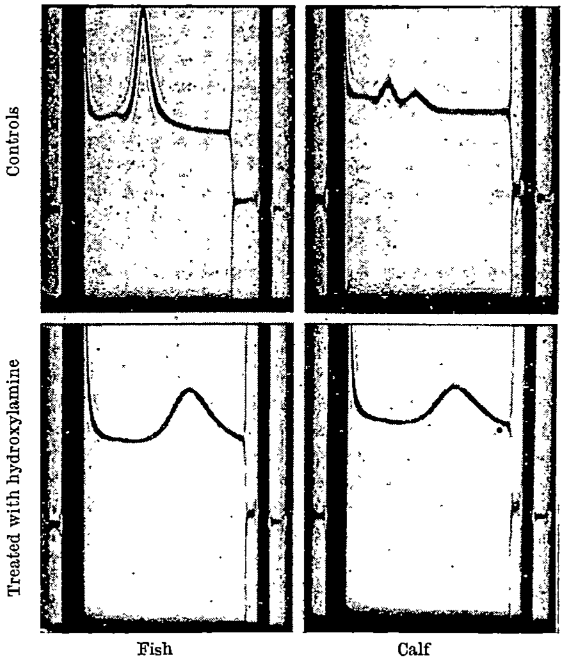

Fig. 1. The sedimentation patterns of parent gelatins obtained from calf and fish procollagens as influenced by treatment with hydroxylamine. The photographs were taken 100 min. after full rotor speed of 59,780 r.p.m. was attained

Only after about 24 hr. at 40° C., however, does treatment with hydroxylamine result in the formation of some dialysable material.

The protein-bound hydroxamide values determined by the methods previously described parallel one another and indicate that about 1 hydroxamide equivalent per 20,000 molecular weight unit is formed during the fast reaction with calf, fish, or acid-processed gelatin. The fast reaction with base-processed gelatin is characterized by the formation of about half this amount of bound hydroxamide, and the slow reaction with this gelatin also shows less hydroxamide production. Such a result is to be expected since ester-like bonds in gelatin could be disrupted by processing with base, and since gelatin produced in this manner contains about 60 per cent less amide nitrogen than does acid-processed gelatin.

We believe that the results summarized above establish the presence of ester-like or perhaps imide linkages between units or chains of about 20,000 molecular weight. It is these units which may be joined together in parent gelatin, or more specifically the α-unit of procollagen, which has a molecular weight of 70,000–80,000. It is of further interest that the components formed by treatment with hydroxylamine retain the capacity to form a gel when used in suitable concentrations of 3 per cent or more.

Grassmann *et al.*[12] and Konno and Altman[13] offered evidence for ester linkages in different collagens using the method of reduction with lithium borohydride. When finely pulverized acid-processed gelatin was suspended in anhydrous tetrahydrofuran containing lithium borohydride, and the mixture refluxed for 30 hr., we could not demonstrate changes in the ultracentrifuge pattern of the protein as compared with a suitable gelatin control; nor did the treated gelatin show a decrease in the amount of hydroxamide formed upon subsequent reaction with alkaline hydroxylamine. Thus it may be concluded that treatment of acid-processed gelatin with lithium borohydride under these conditions does not affect the internal ester-like bonds which are severed when the protein is made to react with hydroxylamine, although it may cause the reduction of terminal ester bonds in native collagens as described by the workers mentioned previously.

An inter-chain acyl shift appears unlikely as an explanation for the action of alkaline hydroxylamine, since the base favours the peptide form. However, in the case of an intra-chain ester-peptide acyl shift involving a residue of hydroxylysine, the ester form may be stabilized by the formation of an oxazoline ring, which, moreover, would probably be sensitive to treatment with hydroxylamine. Should this be the case, it may not be fortuitous that hydroxylysine is present in gelatin in an amount consistent with the bound hydroxamide formed after treatment with hydroxylamine, and this amino-acid might be serving a unique function of cross-linking.

We have begun experiments to separate the components of gelatin after treatment with hydroxylamine, and thus far have isolated two hydroxamide-positive fractions by electrophoresis on paper or starch at *p*H 4·0 in 0·05 *M* acetate buffer. It is our intention to degrade each of the components with bacterial collagenase, and, by suitable analysis, establish the nature of the hydroxylamine-sensitive linkages in gelatin.

Other proteins have been treated with alkaline hydroxylamine for 3 hr. at 40° C., and although several have yielded positive tests for protein-bound hydroxamide, none has formed as much as one-fifth the amount found when equivalent quantities of gelatin are used. Thus crystalline bovine serum albumin, insulin, salmine, and myosin gave detectable hydroxamide reactions, whereas ribonuclease and adrenocorticotrophic hormone did not. Except for albumin, ultra-centrifuge studies were not done, so that it cannot be ruled out that the bound hydroxamide was formed as a result of the splitting of terminal ester bonds or of particularly sensitive amide bonds. Treated albumin, however, showed no diminution of molecular weight as determined in the ultracentrifuge, but rather exhibited a peculiar, and as yet unexplained, aggregation of molecules.

It is also of interest that gelatin, esterified chemically, and afterwards treated with hydroxylamine, showed a large increase in protein-bound hydroxamide as compared with a suitable control.

Gelatins can also be treated with aqueous 1 *M* hydrazine at *p*H 8–9 at 40° C. for 2–5 hr. to cause a cleavage of the protein similar to, though less rapid than, that obtained with hydroxylamine. The products formed are less soluble than the corresponding hydroxamides, but, like the latter, retain a capacity for gelation. They are non-dialysable, and appear to be protein acid hydrazides which can react quantitatively with *p*-dimethylaminobenzaldehyde in acid solution, and which also can reduce copper salts quantitatively. The protein hydrazides can be treated with fluorodinitrobenzene to yield derivatives which are red under mild alkaline conditions (for example, producing red spots on filter paper when exposed to ammonia vapour), and which presumably are dinitrophenyl hydrazides. Both the protein hydrazides and the dinitrophenyl derivatives of these can be digested with collagenase, and the special chromatographic characteristics of the peptides formed are being used at present to establish the precise nature of the bonds cleaved by hydrazine.

In conclusion it may be stated: (1) that various kinds of gelatin are cleaved by either hydroxylamine or hydrazine under conditions favouring the disruption of ester bonds; (2) that these reactions occur without the concomitant splitting of peptide bonds; (3) that the products are non-dialysable proteins of about 20,000 molecular weight which react in one instance as hydroxamides and in the other as acid hydrazides. The results strongly suggest that ester-like bonds exist in parent gelatin, and that the specific disruption of these releases fundamental sub-units of the protein molecule.

Corpuscular Radiation and the Acceleration of Artificial Satellites

In a previous communication[1] I showed that the secular accelerations of Satellites 1958 β 2 and 1958 δ 1 varied nearly in unison with the 10·7-cm. radiation from the Sun. This correlation sheds no light on the nature of the radiation responsible for the variations of density of the upper atmosphere, since the 10·7-cm. radiation—the variations of which are remarkably similar to those of the sunspot numbers—can obviously be considered only as a general index of solar activity. To obtain further clues on this subject I reduced anew all the available observations of these two Satellites (about 2,500 for 1958 β 2 and 9,000 for 1958 δ 1) with the best elements at hand and obtained more accurate accelerations at twice the original resolution. The results are plotted in Fig. 1, together with the 10·7-cm. solar radiation curve[2]. As can be seen, the correlation with the solar radiation is remarkably good, even in details, for the high-flying, spherical *Vanguard* Satellite 1958 β 2, for which accurate, well-distributed Minitrack observations were available throughout. For 1958 δ 1 the observations are mostly optical, less accurate and more irregularly distributed, with occasional periods of near-invisibility; this fact, together with the elongated shape, may have contributed somewhat to the poorer correlation in its case.

The procedure for computing the accelerations was as follows. Residuals of individual nodal (for 1958 δ 1) or perigee (for 1958 β 2) passages from empirical equations were plotted and ordinates on the residual curves were read off at intervals of 25 revolutions; differences were taken from the resulting table and accelerations were computed from them. The residual curve for 1958 δ 1 is a succession of long, smooth waves of great amplitude which are mainly due to the 27-day fluctuations. At only two spots in the whole curve is the smooth succession of long waves interrupted by a transient, short-lived but unmistakable secondary oscillation. The dates of these disturbances are July 8–9 and September 4, 1958; they are exactly coincident with the only two great geomagnetic disturbances that occurred during the life-time of the Satellite. Both magnetic storms followed, at the usual 1-day interval, the appearance of a flare of importance 3 on the Sun.

Although the original accelerations had a resolution of 25 revolutions, it appeared possible to obtain significant accelerations with a resolution of 10 revolutions around the critical dates, and these—computed at intervals of 5 revolutions—are plotted in Fig. 2, together with the 3-hr. geomagnetic planetary indices K_p. It is quite evident that in both the July and the September events there was no immediate response at the time when the flare appeared, and that the atmospheric disturbance—an increase in density—proceeded nearly in synchronism with the magnetic disturbance. The increase in the acceleration amounted to 40 per cent in the July 8 event and to a little more than 30 per cent in the event of September 4. These are actually lower limits, since the limited resolution may have smoothed out the peaks (with a resolution of 25 revolutions the peaks are much reduced, as can be seen in Fig. 1, where the two disturbances are marked (1) and (2) respectively). Since the amplitude of the 27-day oscillations did not exceed 20 per cent for this Satellite (1958 δ 1), it appears that the corpuscular radiation capable of causing a first-rate geomagnetic disturbance has a greater, although more transient, effect on the atmospheric density at the 200-km. level than the ordinary

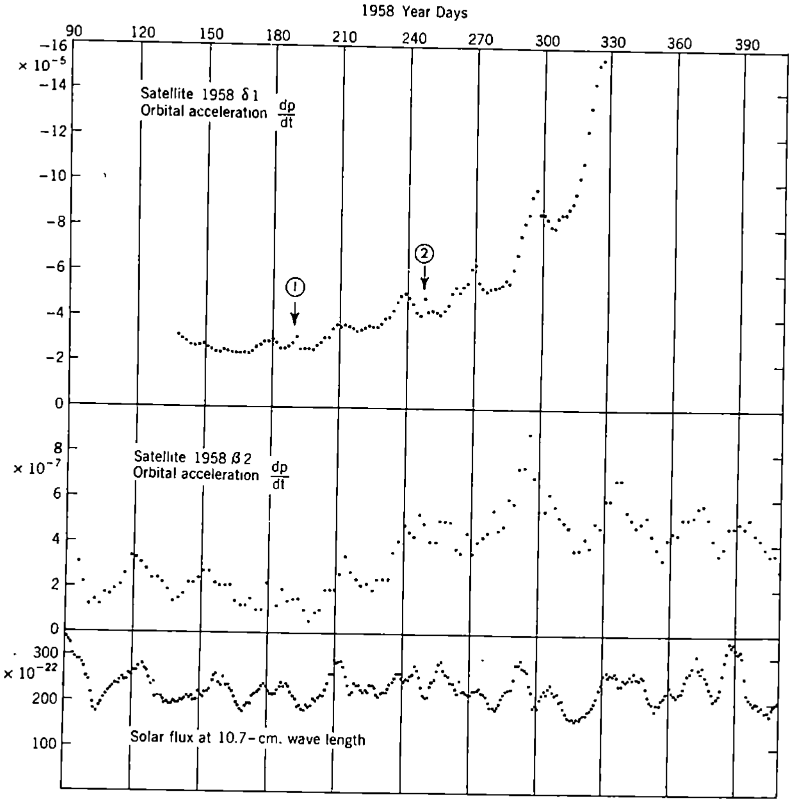

Fig. 1. Secular accelerations of Satellites 1958 δ 1 and 1958 β 2 compared with the 10·7-cm. solar flux. The dates of the two great geomagnetic disturbances, July 8–9 and September 4, 1958, are marked (1) and (2) respectively. Accelerations computed at intervals of 25 revolutions

fluctuation in solar radiation associated with the 27-day period. That this latter radiation is also corpuscular in nature appears quite probable, in view of the failure of the atmospheric density to react promptly to the stream of electromagnetic radiation which accompanies the appearance of a flare.

No disturbance could be detected in the residual curves for 1958 β 2 around the two critical dates in July and September. This may be due to the much smaller value of the acceleration for this Satellite, which would make a short-lived perturbation difficult to detect. It appears quite reasonable, however, that during a violent magnetic storm the atmospheric layers in the 200-km. zone are more strongly affected than those at a height of 600–700 km. If we may judge by the observed increase of the 27-day fluctuations with height[1], it appears that in ordinary conditions the opposite situation prevails, with the higher levels affected more than the lower.

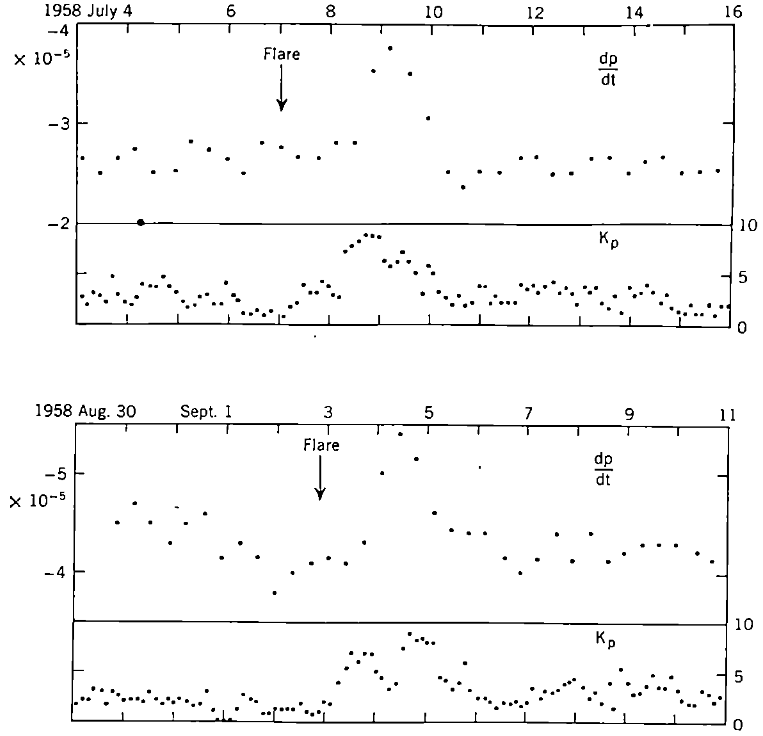

Fig. 2. Secular accelerations of Satellite 1958 δ1 computed with a resolution of 10 revolutions around the dates of two great geomagnetic disturbances and compared with the 3-hr. geomagnetic planetary indices K_p. The instants of the flares that preceded the magnetic storms are marked on the diagram

It might be of interest to remark that at the time of the July disturbance the latitude of perigee of 1958 δ 1 was +35°; at the time of the September disturbance it was +15°.

I am indebted to Mr. Robert Briggs for most of the reductions of the *Vanguard* Satellite observations.

A High-Resolution Survey of the Coma Cluster of Galaxies at 408 Mc./s.

IN December 1958 an area of sky including the Coma cluster of galaxies was surveyed using the 250-ft. radio telescope at Jodrell Bank[1] with a Dicke-type radiometer, pass-band 408 ± 2 Mc./s., and noise figure 6 db. The beam was elliptical, having half-power widths of 40 and 56 minutes of arc. The system was calibrated using the radio source 14*N*5*A*, which was assumed to have a flux of 47×10^{-26} W. m.$^{-2}$ (c./s.)$^{-1}$ (ref. 2). The intensity contours for the region are shown in Fig. 1; Fig. 2 is a sample scan through the cluster and Table 1 gives the fluxes and positions of sources which can be resolved from the extremely complex background.

These results confirm the earlier report by Seeger, Westerhout and Conway[2] that radiation is detectable from the vicinity of the Coma cluster. The new feature of the present survey is the resolution of this radio emission into at least three distinct sources, *A*, *B* and *C* (see Table 1). Of these sources, *A* and *B* are point sources (that is, less than 30 minutes of arc in diameter) since they do not broaden the beam. Source *C* is appreciably extended and could consist of two sources separated by 40 minutes of arc. Although it is apparent from inspection of Fig. 1 that there is a concentration of sources near the centre of the cluster, it is possible that these are not associated with the cluster but are fortuitously coincident with it. The probability of such a coincidence is about 1 in 30. This figure is derived from the number-intensity diagrams given by Mills, Slee and Hill[4] in their survey of radio sources in the southern hemisphere. Thus it is reasonable to assume that some of these sources are physically associated with the cluster.

Current views are that the radio emission from clusters of galaxies may be separated into three components, namely, the normal emission from galaxies[5], the emission from intergalactic gas[6], and emission from abnormal systems. It is important to decide on the relative contributions from these three components for the Coma cluster. Baldwin and Elsmore[7] have shown that in the Perseus cluster

* Distributed source.

75 per cent of the emission at 80 Mc./s. originates in an abnormal object (*NGC* 1275), which is two galaxies in collision, and the remaining 25 per cent in a much broader component. We have measured the flux from *NGC* 1275 at 408 Mc./s. and find it to be 36 × 10^{-26} W. m.$^{-2}$ (c./s.)$^{-1}$. As the flux of the sources *A*, *B* and *C* is within an order of magnitude of this, they could be peculiar objects within the Coma cluster.

In the presence of these sources, which we shall provisionally assume to be associated with peculiar objects, it is difficult to determine whether a broad component of radio emission exists which is co-extensive with the optical limits of the cluster. If the general background brightness temperature is 2° K., the total emission from the cluster is 26 ± 6 × 10^{-26} W. m.$^{-2}$ (c./s.)$^{-1}$. The total emission from the sources in the cluster is 20 ± 5 × 10^{-26} W. m.$^{-2}$ (c./s.)$^{-1}$. Therefore if a distributed component exists it does not contribute more than 25 per cent to the total emission. This sets an upper limit to the possible contribution from the intergalactic medium and from all the normal galaxies in the cluster.

The outstanding problem is to determine which of the discrete sources are associated with the cluster. For this purpose accurate position measurements are required so that optical identifications can be made.

We thank Prof. A. C. B. Lovell for making available the facilities at Jodrell Bank, and Mr. R. Hanbury Brown for suggestions and criticisms throughout the course of the work. One of us (D. S. M.) gratefully acknowledges a Leverhulme Research Fellowship.

Frequency of Meteorite Falls throughout the Ages

PROF. HANS PETTERSSON has pointed out[1] that the late Prof. F. A. Paneth's statement that "iron and stone meteorites did not fall before the later Quaternary"[2] must be modified since cosmic spherules formed by the ablation of meteorites in the Earth's atmosphere are found in the deepest sections of cores of sediments from the Pacific Ocean dating back to Tertiary times.

There is other evidence which suggests that meteorites have fallen on the Earth's surface at least as far back as the Tertiary. Henderson and Cooke[3] have described the unusual occurrence of the Sardis coarse octahedrite, from which they have concluded that this iron meteorite may have fallen into the middle Miocene sea and become buried by the slowly accumulating middle Miocene 'Hawthorne formation' with which it is now associated. Of even more importance is a previously unpublished report that an iron meteorite was found at a sub-surface depth of 1,525 ft. in an oil well drilled in Zapata County, Texas. The circumstances of the find have been described by M. Williams and forwarded in a personal letter dated September 14, 1956, by E. A. Wendlandt, chief geologist of the Humble Oil and Refining Company.

During the drilling of the well in 1930 an extremely hard object was struck at a depth of 1,525 ft. and in sediments of almost certainly Eocene age. This object was recovered and found to be a piece of metal about the size of a man's fist. An approximate analysis of a 0·4-gm. sample by M. Williams indicated about 82 per cent iron, 5–10 per cent nickel and traces of phosphorus, carbon and silicon. Two surfaces were polished and on etching Widmanstätten figures were quite distinctive. It would seem almost certain that the metal fragment was an octahedrite iron meteorite, but unfortunately the specimen has since been lost. There does not seem to be any reason to doubt the authenticity of the find, and the fact that the meteorite was embedded in Eocene sediments at a considerable depth from the surface could only mean that the meteorite fell in Eocene times.

Recent determinations of 'cosmic-ray ages' of certain meteorites indicate that they were broken from their parent bodies about 10^9 years ago[4]. In these circumstances meteorites have probably been available to fall on the Earth since at least early Palæozoic times. However, most meteorites are unstable on the Earth's strongly oxidizing surface, so that it would be most unlikely that they would be preserved in any readily recognizable form in sediments older than Tertiary. Since cosmic spherules are already largely fused and oxidized, they might be expected to be more stable and perhaps preserved in sediments considerably older than Tertiary.

Some Experiments with an Electrodeless Discharge

Although various thermonuclear devices such as *Scylla*[1] employ electrodeless discharges to generate strong shock waves in a gas such as deuterium, with the exception of some exploratory experiments of Janes and Patrick[2], there are no reports of attempts to study the basic phenomena in such devices. An investigation of electromagnetically driven shock waves generated by this method is therefore being undertaken at the Atomic Weapons Research Establishment, Foulness.

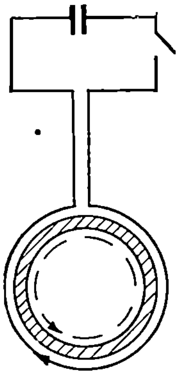

Fig. 1. Diagram of electrodeless apparatus for producing converging shock waves

The apparatus used is shown schematically in Fig. 1. A single-turn coil is wrapped around a 'Perspex' cylinder with 'Perspex' end-walls. The dimensions of the 'pill box' so formed were 3·1 cm. diameter by 2·2 cm. long, and this chamber was filled with deuterium to some known pressure between 0·1 and 2 mm. mercury.

A rapidly rising current was produced in the single-turn coil by suddenly switching an 8 μF. low-inductance condenser bank across it. Under certain conditions of gas pressure, and aided by some pre-ionization, the e.m.f.'s induced in the gas are sufficient to cause breakdown and a cylindrical current sheet is formed in the gas at the circumference of the pill box. This induced current is in the opposite sense to that in the coil, and the repulsion between the two current sheets gives rise to a strong shock wave in the gas.

Streak camera photographs (that is, radius–time curves) of the motion of the shock front showed that the shock did not reach the centre of the pill box. This result is in accordance with the observations of Janes and Patrick[2] and is attributed to some of the magnetic field from the current in the coil penetrating the discharge before the plasma formed by the shocked gas is sufficiently conducting to prevent diffusion of the magnetic field. This weak magnetic field is then trapped and amplified by the imploding shock until the magnetic pressure is sufficient to reduce the shock to rest.

This theory was confirmed by measurements of the magnetic field made with a coil mounted at the axis of the discharge ; these showed a sudden rise as current began to flow in the coil, followed by a period of relatively constant field as the discharge built up and the gas became conducting. There was then an increase in magnetic field corresponding to the implosion of the shock wave. It was, moreover, found possible to make the shock travel much closer to the axis by putting on a d.c. field to cancel out the field trapped by the imploding shock. The degree of convergence is greatly increased by having a d.c. field of the order of 1,000 oersteds. For fields greater than this, the degree of convergence falls again, since the effect has been over-corrected. Also, with fields of the order of 1,000 oersteds, the speed of the imploding shock is increased, presumably because little work is done in compressing the small trapped magnetic field. This may well have important applications to the production of high-temperature plasmas, since the temperature of a shocked gas varies approximately as the square of the shock speed.

The interaction of the imploding shock with the trapped magnetic field is of some interest since it is an addition to the small number of cases where hydromagnetic interactions may be observed on the laboratory scale with magnetic Reynolds numbers in excess of unity. The magnetic Reynolds number may be defined by :

$$R_m = 4\pi\sigma U r_0 \qquad (1)$$

where σ is the conductivity of the plasma (E.M.U.), U is the shock speed (cm./sec.) and r_0 is the radius of the apparatus (cm.).

The physical significance of magnetic Reynolds number is that, in hydromagnetic phenomena, the magnetic lines of force diffuse through the medium or are fixed to conducting particles of the medium if R_m is much less or greater than unity respectively. On the cosmic scale, the linear dimensions r_0 are so large that R_m is normally much greater than unity. On the laboratory scale, however, r_0 is usually limited to the order of ten centimetres, and most attempts to study hydromagnetic phenomena at large R_m have employed highly conducting liquids. The present experiment achieves a high R_m by means of high velocity, U, and fairly high conductivity, σ.

A theory of the variation of trapped magnetic field with shock radius has been formulated and the results presented as a power series in $1/R_m$. The first two terms give a field variation in the form:

$$H \propto \{r(r + \delta)\}^{-(1 - 1/\eta)} \qquad (2)$$

where $\delta = \eta/2\pi\sigma U$, and r is the shock radius (cm.) at time t (sec.), and η is the ratio of densities across the shock front.

This variation has been computed for various shock speeds, the temperature of the shocked gas (and hence σ, ref. 3) being determined from the Rankine – Hugoniot equations taking the ionization and dissociation energies of deuterium into account. The results are presented in Table 1. It will be seen how rapidly the magnetic Reynolds number increases and the distance δ decreases with increasing shock speed.

Table 1

Shock speed (cm./μsec.)	Temperature of shocked gas (° K.)	Conductivity σ (E.M.U.)	Magnetic Reynolds number for apparatus 1-cm. radius	Compression (η)	δ (cm.)
6·0	$5{\cdot}0 \times 10^4$	$2{\cdot}8 \times 10^{-7}$	2·1	7·8	0·74
7·0	$7{\cdot}9 \times 10^4$	$5{\cdot}7 \times 10^{-7}$	5·0	6·3	0·25
8·0	11×10^4	$9{\cdot}3 \times 10^{-7}$	9·3	5·6	0·12
9·0	15×10^4	15×10^{-7}	17	5·3	0·06
10·0	19×10^4	21×10^{-7}	26	5·0	0·04

Equation (2) may be expressed in the form:

$$\frac{1}{H}\frac{dH}{dt} = -U\left(1 - \frac{1}{\eta}\right)\left\{\frac{1}{r} + \frac{1}{r + \delta}\right\} \qquad (3)$$

The values of $\frac{1}{H}\frac{dH}{dt}$ obtained theoretically from this formula have been compared with the values obtained experimentally with the small field-measuring coil. Preliminary measurements indicate that the theory accounts reasonably well for the experimental results.

Another phenomenon that has been observed is that the gas will not break down on the first half-cycle of the oscillatory current in the single-turn coil when the condenser bank is switched across it if the ambient deuterium pressure is below a certain critical value.

An approximate theory of this effect has been derived by postulating that electrons multiply by a Townsend ionization-by-collision mechanism until a certain cut-off time. Providing this time is longer than a certain amount, the gas is sufficiently ionized to become highly conducting and then breaks down with the formation of a shock wave on the first half-cycle. If it is supposed that the cut-off time is determined by a spiralling motion of the electrons in the rising magnetic field due to the current flowing in the single-turn coil, and that when the field has risen above a certain amount the electrons do not travel a sufficient distance in the direction of the induced electric field to have enough energy to ionize by collision, it can be shown that a shock wave is formed on the first half-cycle only if:

$$r_0 V \alpha \gtrsim 6{\cdot}5 \times 10^4 \qquad (4)$$

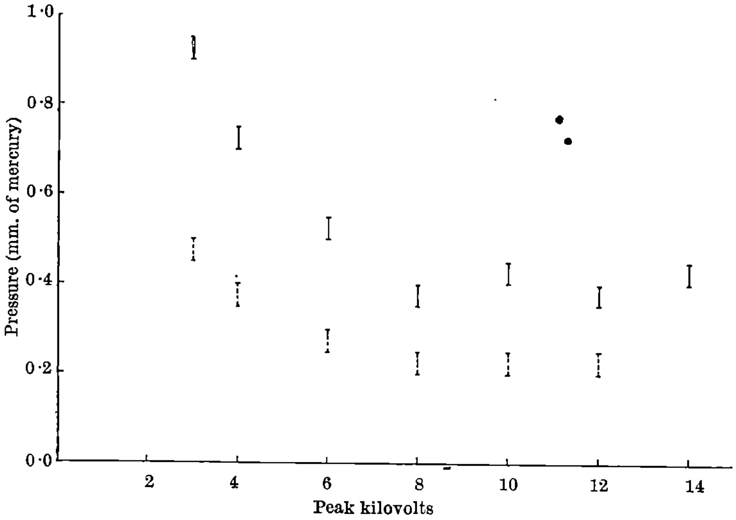

Fig. 2. Minimum breakdown pressure at various voltages for electrodeless discharges of 3·1-cm. diameter (full lines) and 6·2-cm. diameter (broken lines)

where r_0 is the radius of the discharge chamber (cm.), V is the voltage across the coil, α is Townsend's first ionization coefficient.

α is a function of the applied electric field (X in V./cm.) and gas pressure p (in mm.). Experimentally determined values of the minimum pressure at which the first quarter-cycle of the primary voltage produces breakdown are shown in Fig. 2. These values are for two geometrically similar sets of apparatus of different radii. The dependence of the minimum pressure for breakdown on voltage at a given radius is approximately in accord with equation 4, while the predicted dependence on radius for a given voltage is almost exactly fulfilled.

Values of α/p calculated from these curves by means of equation 4 are about twice as large as those determined by Hale[4] and Rose[5]; but in view of the approximations made in the theory, this is considered to be satisfactory agreement.

A full account of the experimental and theoretical work will be published elsewhere. We are indebted to the Director of the Atomic Weapons Research Establishment for permission to publish this communication.

Use of Synthetic Quartz Crystals as a Support for Specimens in Powder Photographs

In the course of experiments on the hydrothermal growth of quartz crystals from aqueous alkaline solution by the temperature gradient method[1], thin needle-shaped crystals were obtained from the autoclave adhering to the cooler portions of the inside

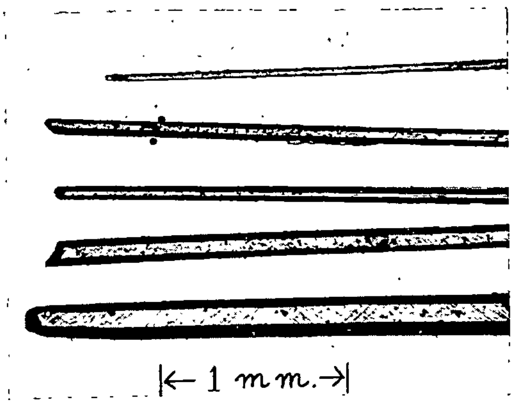

Fig. 1. Examples of needle-shaped synthetic quartz crystals of varying diameters

wall, to the bottom of the lid, and to the stainless steel support for crystal seeds. The autoclave was made of chromium steel, set vertically and heated from below. The solution contained 2 per cent sodium hydroxide and 3 per cent sodium carbonate by weight. The approximate temperature and pressure of the autoclave were 350–360° C. and 300 atm., respectively. The needles were obtained in large numbers pointing almost at random. The diameters of individual needles were uniform and ranged from 0·03 to 0·2 mm. Their lengths were 5 mm. or more. Typical examples are shown in Fig. 1.

The crystals were elongated in the *c*-axis direction with side surfaces bounded by six prism faces and capped at the free end by three uncompleted major rhombohedral faces. Parallel striations usually observed on the prism faces of natural quartz crystal were not observed with the present ones. Each needle was uniform in cross-section and straight in the *c*-axis direction.

The crystal needles serve as excellent supports for powder specimens in the X-ray Debye–Scherrer technique, since they are strong, perfectly stable to air and to X-irradiation, and highly resistant to heat and chemicals. They can be used repeatedly. Powder samples were fixed to the needle with a thin layer of grease. The adjustment making the long axis of the needle coincident with the rotation axis of the specimen holder of the camera could be carried out accurately, since a sufficient length of supporting crystal was straight. The centring of the powder specimen was performed automatically with this adjustment.

Debye–Scherrer photographs taken by this method are shown in Fig. 2. There is no confusion between the patterns of the quartz and the powder, the former appearing as short specks superimposed on the usual Debye–Scherrer pattern. The diameter of the camera was 57·3 mm. The collimator consisted of two pinholes 0·3 mm. in diameter and 51·5 mm. apart. The camera was equipped with a small goniometer head as a specimen mount.

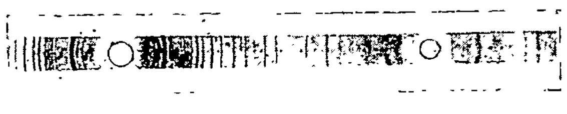

Fig. 2. X-ray powder pattern of germanium and germanium dioxide mixture taken with needle-like synthetic quartz crystal as the specimen support. Radiation, copper $K\alpha$ (filtered)

This method has the following advantages.

(1) The photographs are free from diffuse halos, unavoidable when glass fibres or other amorphous materials are used. This increases the sensitivity for the detection of weak lines.

(2) The equatorial line is easily determined from the rotating crystal pattern of quartz. The centres, $2\theta = 0°$ and $180°$, are easily and accurately obtained.

(3) It gives valuable information on the X-ray spectra giving rise to the powder pattern. Copper $K\beta$, tungsten $L\alpha_1$, or other spectra due to impurities in the target can be recognized by observation of the diffraction spots due to the quartz crystal. The relative intensities of the spectra are also easily obtained.

(4) Departures of the specimen from the correct orientation during exposure is easily detected; the rotation photographs of quartz become similar to 'tilted-crystal' photographs, the diffraction spots becoming longer with the increase in 2θ.

(5) The quartz pattern serves as a good standard for interpolation in the measurement of spacings of the powder pattern. Recently, the variability of lattice constants of quartz crystal by amounts as large as 0·01 per cent has been reported by Keith[2]. Her result shows that the lattice constant, *a*, of synthetic quartz varies from 4·9126 to 4·9131 A., depending on the conditions of its growth. However, for measurements where this amount of variation is negligible synthetic quartz may well serve as a standard.

Measurement of the precise lattice constants of our needle crystals and their variation, if any, under X-irradiation are in progress.

METALLURGY

Crystallographic Orientation of Nodules formed by the Grain Boundary Reaction of Aluminium–Zinc Alloys

ALTHOUGH the grain boundary reaction phenomenon (discontinuous precipitation or cellular precipitation) of aluminium–zinc alloys was reported previously[1,2], the crystallographic orientations of nodules have not yet been determined. As the spacing between lamellar precipitates in nodules of aluminium–zinc alloys is very small, the precipitates cannot be observed by the ordinary optical microscope, but only by the electron microscope, as shown in Fig. 1. If the precipitates in the nodules are oriented in a definite direction, the relationship of the crystallographic orientations between nodules and matrix grains could be determined[3]. Or, if the specimens can be treated by an adequate etching technique to be sensitive to polarized light, the relationship of the orientations can be observed under the polarized illumination[4]; but this was also impossible for the existence of the small precipitates.

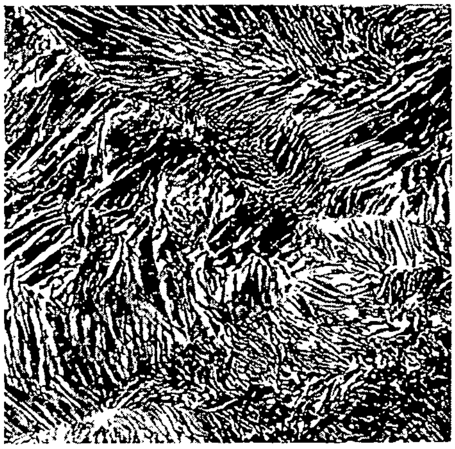

Fig. 1. 25 per cent zinc aged for 250 hr. at 120° C. (× 3,000)

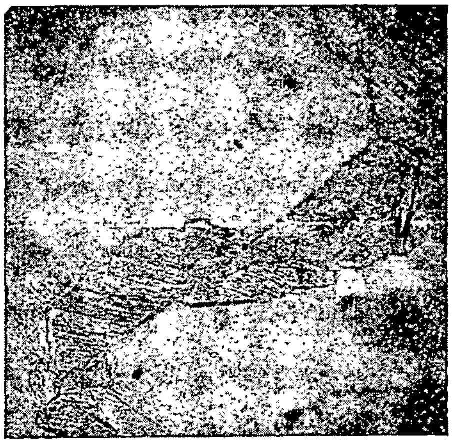

Fig. 2. 25 per cent zinc aged for 600 hr. at 50° C. (× 40)

However, we were able successfully to determine the crystallographic relation by the optical microscope under the polarized illumination after adequate heat treatment and chemical polishing. The technique is as follows. The specimens with nodules produced by ageing, as shown in Fig. 2, are solution heat-treated for a short time, for example about 5 sec., in a salt bath regulated at 470° C. Thus the bulk of precipitates in nodules are dissolved into the matrix and the advancing boundaries of nodules are left as they were. This fact can be observed by means of an optical microscope under polarized illumination after chemical polishing in a solution of 25 parts of sulphuric acid, 70 parts of ortho-phosphoric acid and 5 parts of nitric acid at 135° C., as shown in Fig. 3. In this case, it is most important to keep the temperature of solution at 135° C. exactly, otherwise the specimens are not sensitive to polarized light. The result, clearly shown in Fig. 3, is the same as those obtained in $AlAg_3$, $ZnAg_4$ and $ZnCu_5$ alloys; that is, the crystallographic orientation of a nodule is the same as that of the adjoining grain from which the nodule grew. Moreover, when specimens so treated are aged again, some new nodules are formed at those parts of the advancing boundary which is parallel to the initial grain boundary, but not at the boundary which is normal to the initial one (Fig. 4). This indicates that the growth-rate of nodules depends on the relative orientation of the grain boundaries[6].

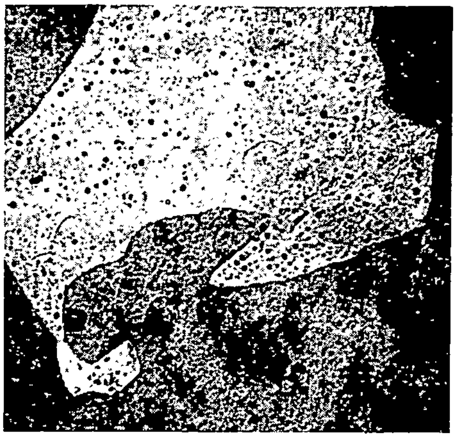

Fig. 3. The same as Fig. 2 except for further heat treatments for 5 sec. at 470° C. (× 40)

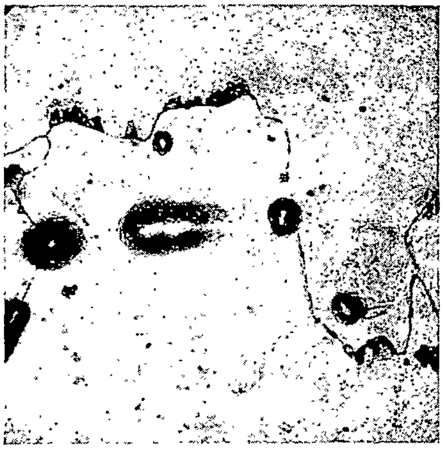

Fig. 4. 25 per cent zinc aged for 10 hr. at 100° C., heat treated for 5 sec. at 470° C. and re-aged for 1½ hr. at 100° C. (× 200)

CHEMISTRY

Alicyclic Structures in Coals

X-RAY and other physical and chemical evidence indicates that coals assume a graphitic structure with metamorphism. X-ray diffraction patterns of some meta-anthracites show (*hkl*) reflexions that arise from the three-dimensional unit cell of a graphite lattice[1,2]. For the anthracites, a number of diffraction bands

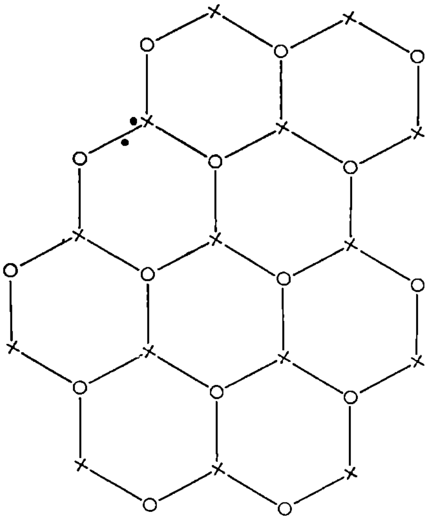

Fig. 1. The molecule used in the calculations. (For the alicyclic case carbon atoms shown as crosses were taken to be in one plane, those as circles in another, that is, a chair configuration)

can be detected which coincide with the (*hk*) reflexions of aromatic layers (having a two-dimensional unit cell of side approximately equal to that of graphite layers)[3]; the remainder of the bands can be attributed to the (00*l*) reflexions of these layers packed 'turbostratically'[4]. Medium- and low-rank coals also give diffuse diffraction patterns that can be indexed as the (*hk*) and (00*l*) reflexions of aromatic layers. These observations led to the development of methods for quantitative analysis of X-ray intensity profiles of coals, permitting estimation of bond-lengths, fraction of carbon in aromatic layers (the remainder assumed to be roentgenamorphous), and size distribution and stacking of the layers[3,5,6].

Coal components rich in hydrogen (more than 6 per cent by weight), for example, exinites[7], resins and some coalified wood[8], show diffraction bands in the angular region where the (*hk*) reflexions of aromatic layers occur. However, the patterns of these components do not have the so-called (002) band. Instead they have a very pronounced peak at smaller angles corresponding to *d*-spacings ranging from 4·3 to 5 A. Despite this ambiguity, exinites were still considered as consisting mainly of condensed aromatic layers, the shift in *d*-spacing being attributed to buckling of the layers or to the presence of more aliphatic material around the edges of the aromatic systems[7].

Treatment of vitrinites with lithium–ethylenediamine results in the addition of considerable hydrogen (as many as 44 hydrogen atoms/100 carbon atoms)[9]. X-ray patterns of treated vitrinites showed extensive changes at moderately low scattering angles[10]. The (002) peak was displaced to lower angles, corresponding to an increase in *d*-spacing from about 3·6 to 4·6 A. Since lithium–ethylenediamine was found to be a powerful hydrogenating agent for aromatic rings without cleavage of C—C bonds[11], the shift of the (002) band to larger *d*-spacings appeared to be consistent with conversion of planar aromatic layers to buckled hydrogenated rings. However, intensity patterns of medium- and high-rank coals treated with lithium–ethylenediamine showed only small changes at high angles, and this seemed incompatible with conversion of aromatic structures to alicyclic or hydroaromatic (partially reduced) structures[9]. Therefore theoretical work on the scattering of alicyclic molecules appeared desirable. Preliminary results of this analysis are presented here, and full details will be published later.

An aromatic molecule containing 30 carbon atoms (Fig. 1) has been chosen as an example. The intensity $J(s)$ in atomic units, scattered at any angle 2θ, was computed by the Debye formula[12]:

$$J(s) = \sum_r \frac{n(r)}{N} \frac{\sin 2\pi rs}{2\pi rs}$$

where $s = 2 \sin \theta/\lambda$, $n(r)$ is the number of interatomic distances of length r within the layer, irrespective of direction, and N is the total number of atoms in the layer. All carbon bonds were taken to be of equal length, 1·4174 A. (cf. ref. 5), and all inter-bond angles to be 120°. After constructing the Patterson function[13] of the molecule and inverting the result by the Debye formula, intensity data were computed numerically on the *Univac* 120. The results are shown in Fig. 2 (dotted line).

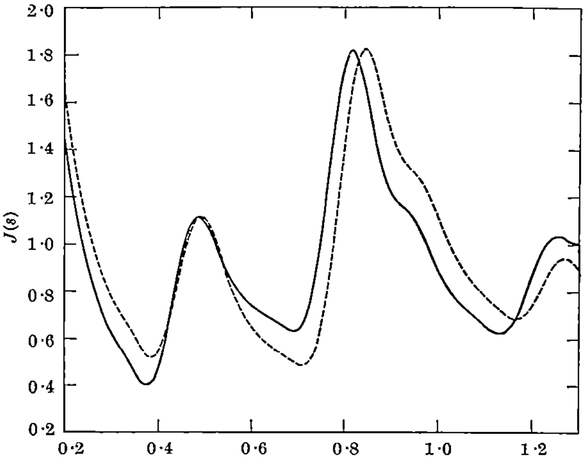

Fig. 2. Calculated X-ray scattering intensities for an aromatic (dotted line) and an alicyclic molecule (solid line) containing 30 carbon atoms (cf. Fig. 1)

A configuration of the alicyclic counterpart of the molecule shown in Fig. 1 was next considered. Carbon atoms shown in the figure as crosses were taken to be in one plane and those as circles in another. All carbon bonds were taken to be 1·5420 A. in length and all inter-bond angles 109° 28·4′, the tetrahedral bond angle. The computed curve is shown in Fig. 2 (solid line).

It is seen that alicyclic molecules give rise to diffraction bands at approximately the same angular region where the (*hk*) reflexions of aromatic molecules occur. The peaks employed for quantitative profile analysis are the (10) and (11) bands of aromatic layers, the first and second peaks from the left, respectively. For the alicyclic molecule shown, the second peak is displaced to a lower angle; however, for other isomeric configurations the displacement is less or even non-existent[14]. It appears that alicyclic or hydroaromatic structure may account to a large extent for the intensity patterns of coal components rich in hydrogen. Indeed, low-rank and even medium-rank coals may contain alicyclic structures in appreciable amounts; diffraction bands of these coals at high angles can be explained by the presence of both alicyclic and aromatic structures. Consequently, it appears that previous quantitative analyses of the X-ray patterns of coal should be re-examined. We wish to thank R. W. Smith for the *Univac* computation.

Characterization of Molecular Weight Distributions by a Viscometric Method

AN indication of the dispersion of the molecular weight distribution in a given polymer sample may be obtained from values of ratios between the different types of average molecular weight as determined by different experimental techniques[1]. For example, the ratio of weight-average to number-average molecular weights ($\overline{M}_w/\overline{M}_n$) is frequently used for this purpose, $\overline{M}_w$ being obtained from light-scattering and $\overline{M}_n$ from osmotic measurements. The utility of such methods is somewhat restricted because of the uncertainties associated with determinations of the individual molecular weight averages in certain regions of the molecular weight range. Osmometry, in particular, is less accurate for both low and very high molecular weights. Since the percentage error in the derived ratio is approximately the sum of percentage errors of the individual determinations, it is evident that quoted values of $\overline{M}_w/\overline{M}_n$ in the region of 1·05 (typical of a sharp polymer fraction) must be accepted with reserve, because such a figure implies a greater accuracy in the individual methods than their current state of development would appear to warrant. If similar ratios could be obtained by the use of a single technique part of the uncertainty as to the magnitude of possible error would be eliminated. It is the purpose of this communication to propose a method for characterizing the dispersion of a molecular weight distribution based on the measurement of limiting viscosity numbers alone.

The method requires a knowledge of the constants K,a of the Mark–Houwink equation relating the limiting viscosity number $[\eta]$ to the molecular weight M of monodisperse polymer:

$$[\eta]_A = K_A M^{a_A} \qquad (1)$$

$$[\eta]_B = K_B M^{a_B} \qquad (2)$$

Here the subscripts A and B refer to different solvent systems, A being a good solvent and B a poor solvent for the polymer, such that $a_A > a_B$ [1]. The viscosity-average molecular weight $\overline{M}_v$ of polydisperse polymer is then defined by:

$$[\eta]_A \text{ (polydisperse)} = K_A \overline{M}_{vA}{}^{a_A} \qquad (3)$$

$$[\eta]_B \text{ (polydisperse)} = K_B \overline{M}_{vB}{}^{a_B} \qquad (4)$$

It can also be shown[1,2] that:

$$\overline{M}_v{}^a = M_0{}^a \sum_1^\infty w_r r^a \qquad (5)$$

in which w_r is the weight fraction of species of chain length r and molecular weight rM_0. Thus:

$$\frac{\overline{M}_{vA}}{\overline{M}_{vB}} = \frac{\left[\sum_1^\infty w_r r^{a_A}\right]^{1/a_A}}{\left[\sum_1^\infty w_r r^{a_B}\right]^{1/a_B}} \qquad (6)$$

from which it may be shown, using Hölder's inequality, that:

$$\overline{M}_{vA} > \overline{M}_{vB}, \text{ if } a_A > a_B \qquad (7)$$

It follows that the ratio $\overline{M}_{vA}/\overline{M}_{vB}$, which is a function only of a_A, a_B and the molecular weight distribution of the polymer, may serve as an indication of the degree of polydispersity.

In order to illustrate the application of the method to particular cases it is convenient to use the generalized exponential distribution[3,4]:

$$w_r \, dr = \frac{r^z \lambda^{z+1} \exp(-\lambda r)}{\Gamma(z+1)} dr \qquad (8)$$

where

$$\lambda = z/\bar{r} = (z+1)/\bar{r}_w \qquad (9)$$

and in which $\bar{r}$, $\bar{r}_w$ are the number- and weight-average chain-lengths respectively. z is a number which characterizes the type of distribution. Thus $z = 1$ corresponds to the so-called 'most probable' distribution, $z = 2$ to the distribution for low-conversion vinyl polymerizations in which termination occurs exclusively by combination of radicals[3], and increasingly larger values of z correspond to increasingly sharper distributions such as may be expected for fractionated polymer. For this generalized distribution it can be easily shown that:

$$\frac{\overline{M}_{vA}}{\overline{M}_v} = \left[\frac{\Gamma(z+1+a_A)}{\Gamma(z+1)}\right]^{1/a_A} \left[\frac{\Gamma(z+1)}{\Gamma(z+1+a_B)}\right]^{1/a_B} \qquad (10)$$

Values of this ratio are given in Table 1, together with the corresponding ratios, $\bar{r}_w/\bar{r}$, for various values of z, and for values of a_A of 0·80, 0·70, 0·60, assuming a_B to be equal to 0·50 (as in a theta-solvent).

The differences between the ratios $\overline{M}_{vA}/\overline{M}_{vB}$ for different distributions, although small, are suffi-

Table 1

z	$\bar{r}_w/\bar{r}$	$\overline{M}_{vA}/\overline{M}_{vB}$		
		$a_A = 0.80$ $a_B = 0.50$	$a_A = 0.70$ $a_B = 0.50$	$a_A = 0.60$ $a_B = 0.50$
1	2	1·080	1·053	1·027
2	1·5	1·052	1·035	1·017
5	1·2	1·026	1·017	1·009
10	1·1	1·014	1·009	1·005
20	1·05	1·007	1·005	1·002

ciently large to be detectable by simple viscometric methods in current use. These methods are capable of giving viscosity-average molecular weights to an accuracy of at least 1 per cent. Moreover, Hermans and Kooy[5] have described apparatus with which limiting viscosity numbers may be determined with a precision of better than 0·1 per cent. The proposed method is therefore directly applicable within the limits of precision at present attainable, and has the advantage of requiring only one technique of measurement. In addition, measurements of $\overline{M}_{vA}/\overline{M}_{vB}$ may be made comparatively quickly and only small quantities of polymer are necessary. The accuracy of the method will be affected less by errors in the absolute values of the constants of the Houwink equations for the two solvents than by errors in their relative magnitudes. Since values of these constants in different solvents are often obtained by viscometric determinations on the same polymer samples, little error should arise when constants derived in this way are used.

Direct Examination of the Degradation of High Polymers by Gas Chromatography

Examination of the degradation products of high polymers may give an indication of the mechanism of breakdown, and may also yield information about the structure and composition of polymers and copolymers. Such an examination may be quickly and conveniently effected if the degradation products are characterized by gas chromatography as they are formed. This may be achieved by generating a pulse of degradation products in the chromatographic apparatus, which is so designed that the products are swept into the column with the minimum delay and disturbance.

Two degradation techniques have been applied in this way. In the first method, a few milligrams of polymer sample are used as a dielectric which is broken down by triggering through it a high-energy discharge (up to 2,000 joules). This method has been applied to polyethylene, polyvinyl alcohol, polyvinyl acetate, polyvinyl chloride, polymethyl methacrylate, polystyrene and cellulose acetate. In all cases the degradation is very drastic, the principal products being small unsaturated molecules with acetylene in largest yield. In some cases (for example, polystyrene), 'characteristic' fragments (for example, toluene, styrene, α-methyl styrene) are also obtained; but the yield of these in comparison with the small unsaturated molecules cannot be significantly increased by variation of the experimental parameters. Hence this method is of only limited utility for structure determination, and the secondary thermal effects are so predominant that no information about the mechanism of the primary electrical breakdown is derived.

The second technique may be controlled to give any desired degree of thermal degradation, and has proved to be more versatile in application. The method involves coating or placing the polymer sample on a filament, which can quickly be brought to any specified temperature for a brief period. The temperature calibration of the filament is effected by optical pyrometry and also by melting-point observations. Samples up to several milligrams have been examined, and the sensitivity of the gas chromatography apparatus is such that less than 1 μgm. of a component in the degradation products may be detected.

Two principal applications of this second degradative technique are under investigation. The first is in the rapid estimation of copolymer composition. The procedure here is simply to degrade the copolymer sample at a particular temperature and to measure peaks on the chromatogram characteristic of each constituent of the copolymer; for example, for vinyl chloride – vinyl acetate copolymers the hydrogen chloride and acetic acid peaks have been used. Separate experiments on weighed samples of the pure homopolymers have yielded direct relations between their masses and the sizes of the characteristic peaks, and these relations enable the sizes of the peaks in the copolymer chromatogram to be translated into masses of the two monomers present. In Table 1 the results obtained for three vinyl chloride – vinyl acetate copolymers are compared with those obtained by infra-red analysis.

Table 1. PERCENTAGE VINYL ACETATE IN VINYL CHLORIDE – VINYL ACETATE COPOLYMERS

By infra-red analysis	By degradation
26·7 ± 1·0	26·2 ± 0·8
34·6 ± 1·0	31·4 ± 0·7
44·3 ± 1·0	43·9 ± 0·5

The second application of the technique consists of recording the degradation products from the same sample of polymer maintained for a few seconds at each of a series of temperatures up to 1,000° C. Polystyrene, polyvinyl chloride, polyvinyl acetate and polymethyl methacrylate have been examined in this way, and each polymer gives a characteristic 'spectrum'. (Under the conditions used, the whole temperature-range can be covered in less than half an hour, and the results give a rapid identification of unknown polymers.) The relative proportions of the degradation products at each temperature yield information about the relative importance of the various degradation processes throughout the temperature-range. For example, it can be shown in the case of polyvinyl acetate that simple depolymerization is a relatively insignificant process; that loss of acetic acid is the principal degradation process and occurs at intermediate temperatures, and that the resulting polyacetylene skeleton is much more stable and is degraded principally at the highest temperatures.

This procedure is also being applied to copolymer samples, and a method of distinguishing block from random copolymers is projected.

Full details of this work and of the modifications in hand will shortly be published elsewhere.

Bond Energies of Some Alkali Fluorides

THE attenuation of microwaves by flames containing traces of alkali metals may be used to determine the electron concentration, arising from the ionization of the alkali, in these flames[1,2]. If a halogen is added to such a flame, the electron concentration is reduced directly by the formation of negative ions, and indirectly by the formation of the alkali halide[3,4]. Flame photometric studies show that the halogens also reduce the excess hydrogen atom concentration in the flame[5]; but it has been observed that fluorine has the least effect[6]. This reduction makes it difficult to estimate the bond energies of the alkali halides from microwave studies[7], because of the indirect nature of the arguments used in the estimations[8]. In the case of fluorine, however, the argument is simplified by the unimportance of the negative ion effect, since the electron affinity of fluorine is low relative to the bond energies of the alkali fluorides, and by the much smaller disturbance produced in the hydrogen atom concentration. In addition, the observations are made at high temperatures where the hydrogen atom concentration approaches equilibrium[5] and it is possible to obtain reliable and consistent results, which it is of interest to place on record.

Sodium fluoride has been examined over the temperature-range 2,300–2,600° K., using perfluoromethyl*cyclo*hexane as source of fluorine, and the dissociation constant determined, assuming the dissociation energy of hydrogen fluoride[9] to be 134 kcal. A graphical determination of the dissociation energy (Fig. 1) gives a value of 124 kcal., equivalent to 119 kcal. at 0° K., in agreement with a statistical 'Third law' value of 120 kcal., calculated from the measurement at 2,400° K. It is also possible to estimate the difference between the bond energies of hydrogen fluoride and sodium fluoride directly from the experimental results. This difference is 14 kcal., which indicates that the bond energy of sodium fluoride is 120 kcal. This concordance shows that the disturbing effects described above are, indeed, negligible. Potassium fluoride could not conveniently be examined over this temperature-range; but a statistical calculation at 2,400° K. gave the bond energy as 117 kcal. Lithium fluoride could only be examined at the highest temperature (2,600° K.) and a statistical calculation put the bond energy at 141 kcal. These values are in good agreement with the thermodynamic predictions of Smith and Sugden[10] but differ somewhat from other authorities[11,12]. They are, however, in good agreement with some values determined by flame photometry in these laboratories recently[13].

Tetrahedral Co-ordination in Ni(II)

LINGAFELTER[1] has suggested that the occurrence of blue-coloured $\text{Ni en}_2(NCS)_2$ and $\text{Ni en}(H_2O)_4(NO_3)_2$ for which X-ray evidence gives 6 co-ordination for the nickel atom contradicts the criteria for identifying tetrahedrally co-ordinated Ni(II) suggested in my earlier communication of the same title[2], with the implication that these criteria are invalid.

The basic criterion laid down[2] was the disappearance of the characteristic peak in the region of 400 mμ of octahedrally co-ordinated Ni(II), which usually has a green colour. With the disappearance of this peak, a deep blue colour would be expected to result, other things being equal. A property which would suggest the possibility of a tetrahedral 4 co-ordinate condition would therefore be possession of a blue colour. However, since a shift of the 400-mμ peak to slightly lower wave-lengths could give the same effect so far as the eye alone is concerned, verification by spectral analysis would be an obvious requirement.

Ballhausen[3] has used the absorption spectra of the various stages of complexing of Ni(II) with ethylene diamine to show the spectra of $[\text{Ni en}(H_2O)_4]^{++}$ and $[\text{Ni en}_2(H_2O)_2]^{++}$, and in fact the 400 mμ peak (as well as the others) has been shifted towards lower wave-lengths, but increased, not diminished, in intensity. Dr. R. G. Wilkins, of the University of Sheffield, has kindly shown me a solid preparation of the salt, $[\text{Ni en}(H_2O)_4](NO_3)_2$, which is light blue, and the absorption spectra he has obtained for ice-cold aqueous solutions of the salt correspond closely to that given by Ballhausen[3]. This blue-coloured complex cation therefore meets the criteria for 6 co-ordination of Ni(II), and it is no surprise that X-ray investigation of the related salts verifies this.

My first statement of the mode of identification[2] therefore still stands.

It would appear quite possible that the disappearance of the 400-mμ peak is indicative of tetrahedral co-ordination of nickel(II), and I have no argument with this criterion. My communication was prompted by Katzin's apparent conclusion concerning the configuration of the blue compounds studied by Lifshitz, Bos and Dijkema on the basis of visual colour alone.

A Colour Reaction for Thiosulphinates

Investigations of the chemistry of the thiolsulphinates, both synthetic and of natural provenance, would be aided if a rapid colorimetric test for these compounds were available. Aliphatic thiolsulphinates can be characterized, in part at least, by reaction with thiamine[1] or with cysteine[2] to yield crystalline derivatives; but these methods do not generally distinguish thiolsulphinates from thiolsulphonates, since the latter compounds will also react with these reagents. The addition of sodium nitroprusside[3] solution followed by base will yield orange to red colours in the presence of aliphatic thiolsulphinates or thiolsulphonates. This procedure has found application in paper chromatography[3] in investigations of the formation of thiolsulphinates in plants of the genus *Allium*. In our experience, the colour, however, is very fugitive and is apparently not produced by some aromatic thiolsulphinates.

We have found that addition of a solution of N-ethylmaleimide in *iso*propyl alcohol followed by potassium hydroxide in the same solvent to thiolsulphinates yields pink to red colours. Thiolsulphinates can therefore be distinguished from disulphides, which remain colourless. This is an extension of the colour test for thiols reported by Benesch and Benesch *et al.*[4]. The conditions for the test are essentially the same as described for thiols by these authors. The maleimide derivative and potassium hydroxide are used in dry *iso*propyl alcohol solutions, 0·05 *M* and 0·25 *M*, respectively, and the N-ethyl maleimide is used in a very large molar excess over the thiolsulphinate. The reaction may be applied on paper, in which case the paper containing a thiolsulphinate spot is first dipped in the N-ethyl maleimide solution; dried for 5–10 min., and is then dipped in the potassium hydroxide solution. A pink spot develops immediately where thiolsulphinate is present. The test may also be performed in solution in colorimeter tubes and absorbance or per cent transmittance measured.

For colorimetric analysis, 1 ml. of 0·05 *M* N-ethyl maleimide reagent is added to 0·5–5 μmoles of thiolsulphinate in 1 ml. of *iso*propyl alcohol and then 1 ml. of 0·25 *M* potassium hydroxide solution is immediately added. Intensity of colour is conveniently measured at 5150 A. (absorption maximum 5100 A.). The colour fades rapidly during the first 3 min. and then diminishes at a slower rate. Moderately reproducible results are obtained if the absorbance is measured at a specified time between 10 and 18 min. after the addition of alkali and compared with standard curves obtained from measurements of pure compounds. The intensity of colour varies somewhat with different thiolsulphinates. The reaction has been applied to several synthetic thiolsulphinates ($RS(O)SR$) where R is phenyl, *p*-tolyl, ethyl, *n*-propyl, and 2-propenyl. The purity of these compounds was established by infra-red analysis. An allicin isolate from garlic and a low-temperature vacuum distillate from a fresh onion concentrate (both of which were shown to be free of thiols) responded to the test. The reaction is sufficiently sensitive just to detect 5×10^{-2} μmole thiolsulphinate/ml. of solution.

In certain cases, the reaction will distinguish thiolsulphinates ($RS(O)SR$) not only from disulphides but also from thiolsulphonates (RSO_2SR). For example, *p*-tolyl *p*-toluene thiolsulphonate and phenyl benzene thiolsulphonate give no appreciable colour (indistinguishable from the background due to the reagents). Ethyl ethane thiolsulphonate produces a very faint colour, approximately 2 per cent of the intensity of the colour of the corresponding thiolsulphinate and *n*-propyl-*n*-propane thiolsulphonate gives a colour approximately 14 per cent as intense as that of the propyl thiolsulphinate. On the other hand, the colour produced by methyl methane thiolsulphonate is a third as strong as that of ethyl ethane thiolsulphinate (the corresponding methyl derivative was not available for comparison), although the compound was shown to be free of thiolsulphinate by infra-red analysis. The relatively high colour value given by the propyl thiolsulphonate compared with the corresponding ethyl compound may be a result of small amounts of thiolsulphinate as impurity in the former. Other classes of compounds responding to the test are thiols and thiolesters as shown by Benesch and Benesch *et al.*[4], and S-alkyl *iso*thiouronium bromides and aromatic sulphinic acids. In the spectrophotometric method for determining thiols[5] with N-ethylmaleimide in phosphate buffer, the thiol adds to the double bond of the maleimide as measured by the decrease in absorbance at 3000 A. In *iso*propyl alcohol, however, no addition is observed with aliphatic thiols or thiolsulphinates. Whether the addition of base produces a rapid addition to the double bond followed by other colour-forming reactions or whether the reactions follow a different course is not known.

BIOCHEMISTRY

Direct Determination of Drug Concentrations in Biological Fluids by Polarography

IT is an established fact that part of the initial testing of new drugs involves their estimation in biological fluids from animals or patients receiving the drug. This information is required to establish dosage regimes and to study rates and methods of elimination from the body. Hitherto, the use of physico-chemical techniques such as spectrophotometry, colorimetry and polarography has frequently required a separation of the drug from interfering materials present in the biological fluid. This communication suggests that, in suitable circumstances, the polarographic method can be successfully employed without any such separation.

During the clinical testing of the new anti-tubercular drug 2-ethyl-4-thiocarbamidopyridine (1314 *TH*) it became necessary to determine small concentrations (0·1–5·0 μgm./ml.) of the drug in serum and cerebrospinal fluid, and larger concentrations (>30 μgm./ml.) in urine from patients receiving the drug. Since 1314 *TH* gives a well-defined polarographic wave ($E_{1/2} = -0{\cdot}78$ volt vs. standard calomel electrode at *p*H 7·0) the utility of the polarographic method was investigated. (Full details of the electrochemistry of polarographic reduction of 1314 *TH* and of the methods described below for estimating its concentration in biological fluids will be the subject of further publications.)

It was found that, using a laboratory-constructed, pen-recording polarograph at its maximum sensitivity of 200 mm./μamp., de-gassed, normal sera of the rat, rabbit, horse and human were free from detectable polarographic waves over the potential range −0·1 to about −1·1 volts, using an internal silver wire anode. This potential range is conveniently referred to as the accessible region of potential. Normal rat and human urine were free from polarographic waves only over the region −0·2 to −0·7 volt. Moreover, the slope of the residual current and the oscillations due to growth and fall of drops were much greater than usual.

Accordingly, polarograms of known concentrations of 1314 *TH* in the above sera and cerebrospinal fluid were recorded and a well-defined wave of height proportional to concentration was obtained. There appeared to be no appreciable change of half-wave potential between serum solutions and aqueous solutions of the same *p*H. There was no need to add any extra supporting electrolyte or buffering agent beyond that already contained in the fluid. The limit of sensitivity with present equipment is ~0·2 μgm./ml. but it is hoped that this can be improved by suitable instrumentation. It was necessary to acidify the urine in order to bring the 1314 *TH* wave into the accessible region of potential, and addition of 5 per cent by volume of glacial acetic acid was a suitable procedure. The sensitivity was decreased to about 5 μgm./ml. because of the larger residual current. The polarographic method has been applied to serum, cerebrospinal fluid and urine from patients receiving 1314 *TH*.

Although most of the work on this problem has been devoted to the estimation of 1314 *TH* there seems no reason why any compound should not be estimated, the half-wave potential of which is in the accessible regions of potential and which does not interact significantly with serum proteins. Other compounds studied briefly in these laboratories to which the direct polarographic method can probably be applied are: pyrazine-2-carboxyamide, certain nitrofuran derivatives, *iso*nicotinylhydrazide and terramycin. The latter two drugs possess half-wave potentials close to the negative limit of accessible potential for serum, and some *p*H adjustment may be necessary to obtain highest sensitivities.

Since this preliminary communication was written, my attention has been directed to the work of Teisinger[1] on the direct polarographic determination of nitrobenzene in serum quoted by Brezina and Zuman[2]. It appears that the approach described above is not novel but has lain in abeyance for some twenty years.

Effect of Azaserine (*o*-Diazoacetyl-L-serine) on the Pyridine Nucleotide Levels of Mouse Liver

THE amount of diphosphopyridine nucleotide in mouse liver has been shown to increase upon the intraperitoneal injection of a number of pyridine derivatives[1,2]; nicotinamide is the most effective, raising the level 8–10 times. Although nicotinic acid is as effective as many of the analogues, it appears to inhibit the synthesis when administered with nicotinamide, as compared with nicotinamide alone. Inhibition of synthesis from nicotinamide injection has also been reported with the administration of the purine antagonists 6-mercaptopurine and thioguanine[1,3]. These inhibitions appear to affect only the level of diphosphopyridine nucleotide attained from nicotinamide injection and the rate of its subsequent return to the normal level, but do not appear to affect the basal level normally found in the liver.

Recently, the injection of azaserine has been shown to inhibit markedly diphosphopyridine nucleotide synthesis resulting from nicotinamide injection[4]. Unlike the effects of the other inhibitors of this system, the administration of azaserine alone causes a marked reduction in the normal levels of the pyridine nucleotide.

We have found that subcutaneous injection of azaserine at a dosage of 200 mgm./kgm. rapidly reduces the level of pyridine nucleotide in the liver. The diphosphopyridine nucleotide-levels in the livers of 2–3 months old (*BALB/cAN* × *DBA/2J*) F_1 hybrid mice were followed using the methylethyl ketone method previously described[1]. In Fig. 1, it can be seen that the pyridine nucleotide-level drops to a minimum value, which is about a nine-fold decrease from the level in control mice injected with 0·85 per cent saline, in 1–2 hr.

After reaching a minimum value, the pyridine nucleotide content was found to rise slowly over a 24-hr. period, approaching the level of the saline-injected, control animal. It appears that this dosage is somewhat toxic with approximately 25 per cent of the animals dying between 20 and 24 hr. after injection of azaserine.

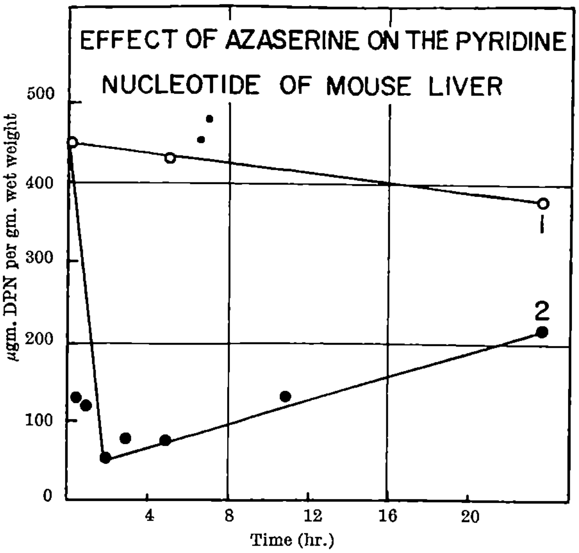

Fig. 1. Effect of azaserine on the pyridine nucleotide level of mouse liver. Determinations were made on a 5 per cent (w/w) trichloracetic acid extract of mouse liver. Each value represents the pooled samples of two mice. Curve 1, saline control; curve 2, azaserine-injected animals

Since the increase in diphosphopyridine nucleotide resulting from nicotinamide administration occurs mainly in the soluble fraction of the mouse liver, it was of interest to determine whether the azaserine reduction acts only on the soluble fraction. Accordingly, four animals were killed 1 hr. after azaserine injection, the livers homogenized in 0·25 *M* sucrose–0·05 *M* nicotinamide solution, pooled, and fractionated according to the method of Jacobson and Kaplan[5]. The results of this experiment, together with the values of the pyridine nucleotide content of livers of saline-injected animals treated similarly are compared in Table 1. Although the soluble fraction shows the greatest change in oxidized nucleotide content, the non-soluble fractions are lower, possibly indicating some equilibrium between the bound and soluble forms in the liver. There does not appear, however, to be an appreciable decrease in the reduced pyridine nucleotide.

Azaserine as well as 6-diazo-5-oxo-L-norleucine has been shown to inhibit synthesis of nucleotide precursors of diphosphopyridine nucleotide[6]. Accordingly, we have found that 6-diazo-5-oxo-L-norleucine behaved similarly to azaserine in lowering mouse liver diphosphopyridine nucleotide.

Inhibition of the precursors of pyridine nucleotide, either by the mechanism described above[6] or one similar to the system reported in red blood cells (also shown to be inhibited by azaserine[7]), would obviously result in a lowered diphosphopyridine nucleotide content of the liver. However, the rate of diphosphopyridine nucleotide destruction in mouse liver as indicated by radioactive experiments[4] cannot in itself account for the rapid decline of diphosphopyridine nucleotide that we have observed after azaserine administration. Furthermore, we have been unable to detect any destruction of diphosphopyridine nucleotide by azaserine under physiological conditions, nor have we observed increased activities of purified veal brain or *Neurospora crassa* diphosphopyridine nucleotidases when they were treated with azaserine. In fact the latter enzyme appears to be inhibited in the presence of high concentrations of azaserine.

Table 1. DISTRIBUTION OF PYRIDINE NUCLEOTIDES IN MOUSE LIVER HOMOGENATES

	µgm./gm. wet weight	
	Control	Azaserine injected
Oxidized		
Total homogenate	477	126
Nuclei	18·2	17
Mitochondria	23·7	12
Microsomes	14·8	8·2
Soluble	360	77·5
Reduced		
Total homogenate	260	198

Mouse livers were removed 1 hr. after azaserine injection. Controls were injected with saline. The values represent the pooled samples of four mice in each group.

Additional investigations are now being carried out in this laboratory in an effort to explain the above observations, and it is hoped that these studies will be of value in elucidating the pathway of diphosphopyridine nucleotide synthesis and its regulation in the intact animal.

This work was aided by grants from the Massachusetts Division of the American Cancer Society, the National Cancer Institute of the National Institutes of Health (Grant *CY*–3611) and the American Heart Association.

Reversal of Epinephrine Inhibition of Liver Tyrosine Oxidation

THYROID hormone interacts with the rat liver tyrosine oxidase system *in vitro* and *in vivo*[1]. The site of the inhibition proved to be at the first enzymatic step of the system, namely, tyrosine-α-ketoglutarate transaminase[1,2]. Canellakis and Cohen[3] first demonstrated an inhibition of this enzyme by epinephrine, using the enzyme from dog liver. Since, under certain conditions, thyroxin and epinephrine are metabolically related[4], it seemed likely that a demonstration of a similar action of both these hormones on the same enzyme system might provide a basis for exposing a mechanism of hormone action. Some empirical effects of epinephrine upon blood amino-acid levels are known[5-7]; but virtually no attempts have been made to explain these results at the molecular level.

The effects of treating a soluble cytoplasmic tyrosine oxidase preparation from rat liver[8] with increasing

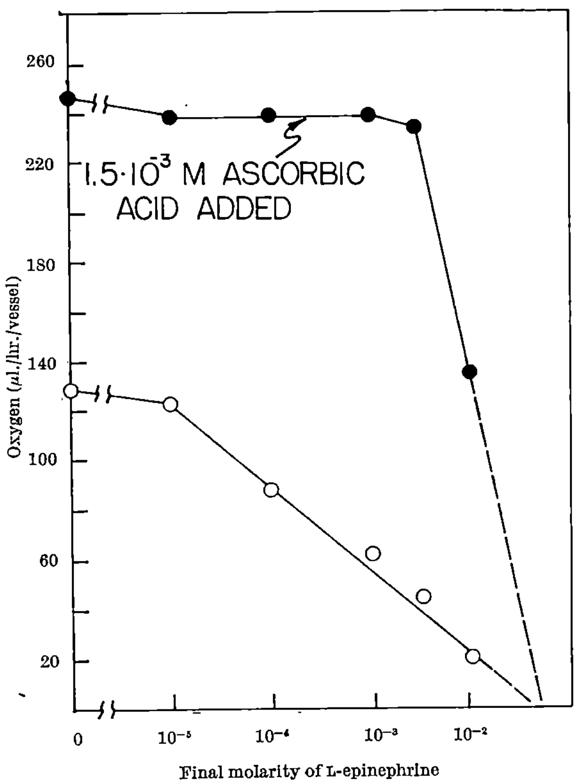

Fig. 1. Reversal of epinephrine-inhibited tyrosine oxidase. Open circles denote control curve without ascorbic acid; solid circles denote addition of $1 \cdot 5 \times 10^{-3} M$ ascorbate to each system. Epinephrine was incubated with the enzyme for 10 min. at 37° C. prior to addition of the substrate

concentrations of L-epinephrine showed that complete inhibition would occur at a level of $5 \times 10^{-2} M$ epinephrine compared with a saturation-level of L-tyrosine co-substrate of about $2 \times 10^{-3} M$. Fractionation of the overall 5-step system into single, double, or triple enzyme sub-systems, using appropriate substrates[8], revealed that inhibition by epinephrine occurs only when tyrosine and α-ketoglutarate are metabolized compared with *p*-hydroxyphenylpyruvate or homogentisate oxidation-rates. This confirmed that the initial enzyme participates in the reaction[3]. Partially purified homogentisate oxidase[9], on the other hand, is usually stimulated by the addition of epinephrine, presumably due to a redox property of the hormone. Complete reversal of epinephrine inhibition of tyrosine oxidation is accomplished by $1 \cdot 5 \times 10^{-3} M$ ascorbate with as much as $5 \times 10^{-3} M$ epinephrine added to the system (Fig. 1). The effectiveness of the vitamin decreases with higher concentrations of the hormone. It is unlikely that ascorbate functions by reducing the stability of epinephrine[10] to an appreciable extent in a system of this *p*H. It seems possible, however, that a chelate may be formed with an essential component and reversed by ascorbate although no evidence is available, as yet, on this point. Other redox agents which stimulate enzymes in the overall system, such as reduced glutathione[11] and dichlorophenolindophenol[12], fail to reverse the hormonal inhibition. Both norepinephrine and adrenochrome are inhibitors. Complete inhibition (extrapolation) occurs at $10^{-2} M$ L-norepinephrine. Only a slight reversal of norepinephrine inhibition is obtained by adding ascorbate to the system in concentrations up to $3 \times 10^{-3} M$. In every case the system can be partially protected by the tyrosine co-substrate if it is incubated with the enzyme prior to addition of the inhibitor. Pyridoxal phosphate, up to $5 \times 10^{-3} M$, fails to reverse epinephrine inhibition of the whole system. That the reversal of epinephrine inhibition by ascorbic acid involves the initial transaminase step is shown by the results in Table 1, where the oxidation-rates of tyrosine and *p*-hydroxyphenylpyruvate in the presence or absence of inhibitor and reversing agent are compared. Compounds such as ascorbyl palmitate, D-*iso*-ascorbate and ferrous ascorbate are as effective as ascorbic acid, but ferrous ion alone does not reverse epinephrine inhibition of the transaminase.

Table 1. RESULTS OF A TYPICAL MANOMETRIC EXPERIMENT SHOWING THE REVERSAL OF EPINEPHRINE INHIBITION TO OCCUR AT THE INITIAL TRANSAMINASE STEP

Substrate ($6 \mu M$)	Addition	Corrected enzyme activity (µl. O_2/hr./flask)	Inhibition (per cent)
L-Tyrosine*		87	
,,	$1 \cdot 5 \times 10^{-3} M$ ascorbate (AA)	169†	
,,	$1 \times 10^{-3} M$ L-epinephrine (EP)	35	58
,,	AA + EP	162	
Keto-*p*-HPP		52	
,,	AA	123†	
,,	EP	50	0
,,	AA + EP	109	

* α-Ketoglutarate present; α-ketoglutarate not added when *p*-hydroxyphenylpyruvate (HPP) is substrate.

† The increase in activity due to addition of ascorbate results from the effect of ascorbate upon homogentisate oxidase (ref. 8).

Physiological significance of this interaction is suggested by *in vivo* experiments which show that intraperitoneal injections of L-epinephrine (1 mgm./kgm. body-weight for 1 hr.), compared with saline-injected rats, produce a 55 per cent inhibition of specific enzyme activity. Addition of $1 \cdot 5 \times 10^{-3} M$ ascorbate *in vitro* causes twice the stimulation of control specific activity in preparations derived from epinephrine-treated animals compared with saline-injected animals. Details and extension of this work will be presented elsewhere.

This investigation was supported in part by a research grant, *A*–1919, from the National Institute of Arthritis and Metabolic Diseases, National Institutes of Health, Public Health Service. The homogentisic acid used was isolated from urine of alkaptonuric patients and generously provided by Dr. B. N. La Du, jun., National Institute of Arthritis and Metabolic Diseases, National Institutes of Health.

Purification of Neuraminidase from *Vibrio cholerae*

Blix, Gottschalk, and Klenk[1] proposed the name 'neuraminidase' for the enzyme which splits the glycosidic linkage joining terminal (substituted or unsubstituted) neuraminic acid to residual oligo- or poly-saccharide. Kuhn and Brossmer[2] and recently Gottschalk and Graham[3] have isolated well-defined substrates by which the enzymatic action of neuraminidase could be studied. There exist many other substrates of high molecular weight and unknown structure; for example, mucoproteins from urine, saliva, serum, or stromata of erythrocytes. Neuraminidase is present in viruses of the myxo-group (influenza, fowl plague, Newcastle disease, mumps) and was found in filtrates of *Vibrio cholerae*[4] and *Clostridium welchii*[5].

To clarify the function of neuraminidase for the virus – host cell relationship it would be desirable to study the structure of the enzyme. Since virus material is not available in sufficient amounts an attempt was made to isolate the enzyme from the culture fluids of *Vibrio cholerae*.

In order to control the purification of the enzyme, a simple method for serial determinations was developed. The basis of this determination is the splitting of neuraminic acid (or its acyl derivative) from a standard substrate. Mucoprotein from human urine was used as standard, which was prepared by a modification of the method of Tamm and Horsfall[6]. Stromata of erythrocytes from sheep or calves were also found to be suitable.

The activity of neuraminidase was measured in the following way. 4 mgm. of urinary mucine containing 3·8–4·1 per cent neuraminic acid was dissolved in 1 ml. water. The enzyme solution (0·001–0·2 ml.) was added and the total volume made up to 2 ml. with 0·1 *M* acetate buffer at *p*H 5·5. This mixture was incubated for 15 min. at 37° C. The reaction was stopped by precipitation of the mucine with 2 ml. of a saturated solution of benzoic acid in chloroform (65 gm./100 ml.). After vigorous shaking, the solution was centrifuged at 3,500 r.p.m. for 4 min. The mucine forms a layer between the chloroform and the supernatant aqueous solution. From the clear supernatant solution 1 ml. was used for the determination of the liberated neuraminic acid by the orcin reaction according to Böhm, Dauber, and Baumeister[7]. A reference curve was obtained using crystalline methoxy-neuraminic acid, kindly supplied by Prof. E. Klenk. The quantity of the enzyme should be adapted in such a way that 8–20 μgm. of neuraminic acid are liberated. The unit *E* of enzyme activity was defined as that amount which liberates 1 μgm. of neuraminic acid in 15 min. at 37° C. under the conditions described. The purity of the enzyme is measured by the specific activity *E*/μgm. protein nitrogen. The nitrogen was determined by the Kjeldahl method if sufficient material was available; otherwise the preparation was hydrolysed by 6 *N* hydrochloric acid and the amino nitrogen was determined by ninhydrin by the method of Stein and Moore[8].

Filtrates of *Vibrio cholerae* cultures supplied by Behring-Werke, Marburg, were used as the starting material. The specific activity could be increased 50,000-fold by a relatively simple procedure. At the beginning of this work, enzyme instability caused certain difficulties. The purified enzyme sometimes lost its activity within a few hours. Sufficient stabilization could be achieved, however, by employing chelating agents. Addition of cyanide was particularly effective during purification, but the enzyme can also be stabilized by serum albumin and other proteins.

Table 1. PURIFICATION OF NEURAMINIDASE

Fraction	Activity (*E*/ml.)	Specific activity (*E*./μgm. nitrogen)	Purification factor
1. *Vibrio cholerae* filtrate	30–60	0·01–0·03	1
2. Concentrate after elution from erythrocytes	200–300	1–2	100
3. Eluate from column chromatography	300–500	120–130	6,000
4. After precipitation with ammonium sulphate	20,000–100,000	1,000	50,000

The first step in purification was the concentration of neuraminidase by adsorption to sheep erythrocytes at *p*H 8–9, followed by an elution at *p*H 5·5, in a way similar to that described by Burnet[4]. Since hæmolysis cannot be avoided, the preparation is heavily contaminated with hæmoglobin.

The following step is the most significant. It may also be useful for the purification of other enzymes which have a high affinity for their specific substrate. This step combines the specific binding of the enzyme to its substrate with column chromatography. Stromata of erythrocytes from sheep or calf, prepared by two-fold hæmolysis, were used as substrate. They were mixed with kieselgur (Merck) to form a chromatographic column. The enzyme was adsorbed at 0° C., *p*H 9 in a buffer containing 0·01 *M* borate, 0·9 per cent sodium chloride and 0·1 per cent calcium chloride. The contaminating hæmoglobin and other proteins were washed out with the same buffer, and the enzyme was eluted at *p*H 5·5 at 0° C. In the adsorption buffer, the enzyme is firmly bound to the substrate, whereas in the acidic medium the substrate is split and the enzyme released.

The eluate from the column was concentrated over phosphorus pentoxide after addition of potassium cyanide. For further purification, the enzyme can be precipitated from the concentrate by half saturation with ammonium sulphate. On the other hand, if a solution containing a lower concentration of ammonium sulphate is slowly evaporated, a protein containing the total enzyme activity is crystallized out in needles.

The concentration of the enzyme and the increase in specific activity during the purification process is shown in Table 1. The purification was repeated several times. In each step of the procedure, 70–80 per cent of the activity was recovered. From the values in Table 1, it may be calculated that the starting material contains 50 μgm. enzyme nitrogen or 300 μgm. enzyme protein per litre. 12 l. of *Vibrio cholerae* filtrate were used in order to obtain sufficient material for ultra-centrifuge studies.

The purified protein is sedimented down with a fairly homogeneous boundary. A sedimentation constant of about $s_{20} = 1{\cdot}3$ S. was measured at *p*H 8·5 in a solution containing 0·02 *M* potassium cyanide. From this value a molecular weight of 10–20,000 is estimated, assuming a spherical shape. Boundaries with higher sedimentation constants were observed under other conditions, suggesting that the protein has a tendency to aggregate. Evidence for the identity of the isolated protein with the enzyme is based on the high specific activity of the protein and the specificity of the purification procedure. Furthermore, it was found that the sedimentation of enzyme activity, measured by the decrease in enzyme activity in the supernatant, was of the same order as the sedimentation constant of the boundary in the ultracentrifuge. Finally, in the purified preparations, proteinases were no longer detectable.

The reaction kinetics of the enzyme was studied in some detail. A Michaelis constant of about $1–2 \times 10^{-4}$ mole neuraminic acid/l. was determined using sheep stromata as substrate. This confirms the high affinity of the neuraminidase for the specific substrate, which made possible the specific purification procedure described here.

Asymmetric Hydrolysis of Diethyl Acetamidomalonate by Chymotrypsin

CONTINUING our study[1] of asymmetry in reactions of non-asymmetric molecules of the type *Ca,b,d,d*, we are examining the hydrolysis of diethyl acetamidomalonate $CH_3CONHCH(COOC_2H_5)_2$ by chymotrypsin. The ester (Matheson) was crystallized from benzene–petroleum ether, m.p. 96·5–98° C. Chymotrypsin was from Worthington, salt free, lot *CD* 576–81. The kinetics of hydrolysis were studied in water at 25°, with magnetic stirring, in the *p*H range 7·0–7·95 with *tris*hydroxymethylaminomethane ($3 \cdot 3 \times 10^{-3}$ *M*) or phosphate ($8 \cdot 3 \times 10^{-3}$ and $1 \cdot 6 \times 10^{-2}$ *M*) buffers. Runs were carried out with a Beckman model *G p*H meter, 0·1 *N* sodium hydroxide being added from a Gilmont micro pipette-burette to maintain the *p*H, or, at high enzyme concentrations, with a *p*H-stat, radiometer titrator and automatic burette delivering 0·4 *N* sodium hydroxide.

The hydrolysis was first order in the ester and the rate 'constants' k_1 were proportional to enzyme concentration (Table 1). The reaction stopped after liberation of one equivalent of acid. The ester was quite stable in the absence of enzyme, its hydrolysis in $3 \cdot 3 \times 10^{-3}$ *M* buffer at *p*H 7·8 showing an apparent k, of 0·0004 min.$^{-1}$. The hydrolysis is first order in both substrate and enzyme under these conditions.

The product of one run, 20 ml. initially 0·02 *M* in the ester was dialysed against 0·001 *N* hydrochloric acid and this was extracted with ether leading to 2-acetamido-2-carbethoxyacetic acid  $CH_3CONH{-}C(COOH)(H)(COOC_2H_5)$, 0·053 gm., 70 per cent yield; m.p. from benzene–ethanol 138–139° dec.; mixed m.p. 139–141°, synthetic sample 140–141°, reported[2] 140–141·5°.

Table 1. HYDROLYSIS OF DIETHYL ACETAMIDOMALONATE BY CHYMOTRYPSIN AT *p*H 7·8 ± 0·15

Chymotrypsin (mgm./ml.)	Ester (*M*)	k_1 (min.$^{-1}$)
0·39	0·0046	0·016 ± 0·001
0·39	0·0092	0·016 ± 0·001
0·39	0·0200	0·016 ± 0·001
0·50	0·0200	0·020
0·10	0·0200	0·042
1·69	0·0637	0·067

The product of a run, carried out in the *p*H-stat at 7·8, with 0·05 *M* ester, an enzyme concentration of 0·91 mgm./ml., and 0·0069 *M* phosphate, was examined in a Zeiss–Winkel polarimeter after 3 hr. reaction, one equivalent of acid having been generated, and was found to be optically active, $\alpha_{obs.} + 1 \cdot 77° \pm 0 \cdot 03$ (after minor correction for chymotrypsin), $[\alpha]^{22}_D + 63° \pm 2$ for the half-ester, based on its presence in quantitative yield as one enantiomorph (the value is not inconsistent with those reported for some derivatives of monosubstituted malonic acids[3]). The rotation fell with time reaching half its original value in about 44 hr. The product of another run carried out with 0·016 *M* phosphate and not examined as quickly led to $[\alpha]^{22}_D$, + 59°. When the hydrolysis was followed in the polarimeter, necessarily in more concentrated (1 *M*) buffer, the rotation rose initially ($\alpha_{obs.}$, + 1·55°) and then fell in 4 hr. to the reading of the blank.

The ester, unlike the related diethyl benzylmalonate, which is rather inert[4] to chymotrypsin under comparable conditions, is hydrolysed by this enzyme to the half-ester. The observed optical activity indicated that this enzyme distinguishes between the two similar ester groups in diethyl acetamidomalonate and that the half-ester is formed optically active and racemized during isolation, presumably by enolization (this kind of steric selectivity has been demonstrated by use of tissue homogenates for citric acid[5] and for glycerol[6]). Isolation of the optically active half-ester is now being attempted. These experiments indicate that the related aminomalonic acid, which is decarboxylated enzymatically[7], may be found to do so asymmetrically, as has been suggested[8], and as would be required by the results of conversion of serine, labelled isotopically in nitrogen and carboxyl carbon, to glycine[9], if aminomalonic acid is to be an intermediate in this process. This is indicated also by reactions of methylmalonic acid[10].

Reduced Diphosphopyridine Nucleotide—Neotetrazolium Reductase

Martius[1] has reported the presence in animal tissues of a quinone reductase (phylloquinone reductase) similar in properties to menadione reductase described by Wosilait and Nason[2]. Phylloquinone reductase couples the oxidation of reduced diphosphopyridine nucleotide (DPNH) with the reduction of vitamin K_3. Since the reduced form of vitamin K_3 reduces neotetrazolium chloride (NT) directly to the coloured insoluble formazan[3], it is of interest to investigate the production of formazan by the enzymic oxidation of reduced diphosphopyridine nucleotide in order to ascertain if this enzymic sequence involves a quinone reductase. In this communication the enzymic process linking the oxidation of reduced diphosphopyridine nucleotide with reduction of neotetrazolium chloride is termed DPNH–NT reductase.

Liver homogenates were prepared either in water or in 0·25 *M* sucrose at 0° C., using a conventional Potter–Elvehjem type homogenizer. The animals used were adult female rats of the Medical Research Council strain, body-weight 180–200 gm.

DPNH–NT reductase was assayed by incubating aerobically 0–20 mgm. wet weight tissue with 1 ml. phosphate buffer (*p*H 7·4, 0·1 *M*), substrate (reduced diphosphopyridine nucleotide, or diphosphopyridine nucleotide plus β-hydroxybutyrate) and 0·15 ml. of 1 per cent neotetrazolium chloride. Buffer, tissue and substrate were pre-incubated for 2 min. at 37° C. aerobically before the addition of neotetrazolium chloride. The reaction was stopped by the addition of 1 ml. of 10 per cent trichloracetic acid; the formazan was extracted with 4 ml. of ethyl acetate. The extinction at 510 mµ was obtained using a Hilger 'Uvispek' spectrophotometer. When other additions were made to the reaction mixture (see Table 1), the reagent added was usually incubated with buffer plus tissue for 15–30 min. at 0° C. Except in those experiments involving differential centrifuging all tissue suspensions were prepared in water to reduce the possibility of permeability phenomena arising with mitochondrial enzymes.

The addition of reduced diphosphopyridine nucleotide (0–1·0 µmole) or of diphosphopyridine nucleotide (0–1·0 µmole) plus β-hydroxybutyrate (final concentration 0·01 *M*) to the incubation mixture led to rapid production of formazan with liver suspensions (Fig. 1). The effects of adding vitamins K_1 and K_3 are also shown in Fig. 1; both vitamins were added in suspension as described elsewhere[4].

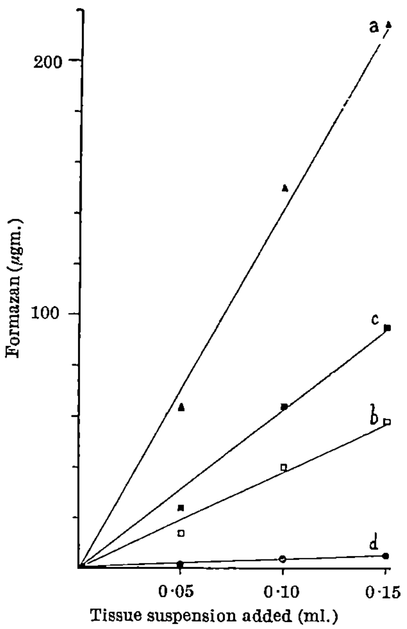

Fig. 1. Formazan production by rat liver tissue suspensions; diphosphopyridine nucleotide + β-hydroxybutyrate as substrate. Curve (*a*), 100 mgm. wet weight tissue/ml.; 1 µmole diphosphopyridine nucleotide; incubation, 10 min. Curves (*b*), (*c*) and (*d*), mitochondrial suspension (1 : 5) frozen and thawed three times; incubation, 15 min.; diphosphopyridine nucleotide, 0·5 µmole; further additions: curve (*b*), 0·1 ml. phosphate/ethanol/plasma albumin suspension; curve (*c*), 0·1 ml. vitamin K_1 (0·3 µmole added) in phosphate/ethanol/plasma albumin; curve (*d*), 0·1 ml. vitamin K_3 (0·8 µmole added) in phosphate/ethanol/plasma albumin

Table 1. ACTION OF VARIOUS INHIBITORS, UNCOUPLING AGENTS, QUINONES AND VITAMINS ON DPNH–NT REDUCTASE

Substrate	Addition (in 0·1 ml.)		Formazan production as percentage of control value
	Substance	Amount (µmoles)	
DPN + BHB*	amytal	2·0	102
DPNH	amytal	12·8	94
DPNH	QMS	5·0	97
DPNH	QMS	10·0	78
DPNH	QMS (anaerobic)	10·0	84
DPNH	quinine sulphate	1·0	100
DPNH	azide	20·0	97
DPNH	versene	20·0	93
DPNH	α,α′-dipyridyl	2·0	92
DPNH	α,α′-dipyridyl	25·0	98
DPN + BHB	manganous chloride	0·4	60
DPNH	manganous chloride	0·4	65
DPN + BHB	2.4-dinitrophenol	0·2	75

DPN + BHB	vitamin K_1	0·3	182
DPNH	vitamin K_1	0·6	111
DPNH	PCMB	1·0	5

* BHB, β-hydroxybutyrate.

Previous reports have indicated that enzymic reduction of tetrazolium salts occurs via a flavoprotein[5]; in an attempt to investigate this possibility the effects of several types of inhibitor were studied. The results are shown in Table 1. It can be seen that sodium amytal, quinine sulphate, α-α′-dipyridyl, sodium azide and sodium versenate had no appreciable effect on DPNH–NT reductase. Quinacrine methane sulphonate (QMS) was inhibitory only in high final concentration both under aerobic and anaerobic conditions. The sulphydryl-reagent *p*-chloromercuribenzoate (PCMB) was strongly inhibitory, as were quinones like 1.4-naphthaquinone, vitamin K_3, and the natural quinone antagonist dicoumerol. Vitamin K_1 was, however, stimulatory in low final concentration. DPNH–NT reductase was inhibited in a variable manner by manganous chloride and by 2.4-dinitrophenol, both of which are known to uncouple oxidative phosphorylation. 2.4-dinitrophenol has also been reported to inhibit quinone reductase and menadione reductase[2].

The results suggest that DPNH–NT reductase, which is an extremely active enzyme in rat liver, does not contain an easily dissociable flavoenzyme complex which would presumably be strongly inhibited by quinine sulphate or quinacrine methane sulphonate. Wosilait and Nason[2] reported that quinacrine produced no inhibition on menadione reductase. It would appear then that if DPNH–NT reductase contains a functional flavoenzyme the flavine group is strongly bound to the protein. A lack of inhibition by quinacrine is not unequivocal evidence for the absence of a functional flavoenzyme.

DPNH–NT reductase does not appear to utilize the amytal-sensitive route connecting oxidation of reduced diphosphopyridine nucleotide with the cytochrome chain[6]. However, it would seem that DPNH–NT reductase involves a quinone structure similar in properties to vitamin K_1 and which can be inhibited by both vitamin K_3 and dicoumerol. The effects of vitamins K_1 and K_3 on DPNH–NT reductase are the reverse of those found for succinate–neotetrazolium chloride reductase[4] but are analogous to the effects of vitamins K_1 and K_3 on oxidative phosphorylation[7]. The effects of such quinones as 1,4-naphthaquinone and vitamin K_3 on DPNH–NT reductase are being investigated further to ascertain if their inhibitory power is an unspecific redox property or is the result of competitive inhibition with another quinone structure.

Using sucrose homogenates the distribution of DPNH–NT reductase in intracellular fractions was investigated. The following centrifugal accelerations for the times indicated were used to separate each fraction: (*a*) nuclear fraction, 600*g* × 10 min.; (*b*) mitochondrial fraction, 10,000*g* × 15 min.; (*c*) microsomal fraction, 105,000*g* × 30 min. The reductase appears to be largely associated with the mitochondrial and microsomal fractions. In a typical experiment the percentage of the total activity associated with each fraction was: nuclear, 8; mitochondrial, 60; microsomal, 28; and soluble fraction, 3.

I am grateful to Dr. A. L. Greenbaum and D. N. Planterose for many helpful comments. The work was done during the tenure of a Beit Memorial Fellowship.

Carotene Content of *Ulex europaeus* (Common Furze)

A GENERAL investigation has been in progress for some time in this Department into certain aspects of the chemistry of *Ulex europaeus*. This common furze has a local reputation as a supplementary animal foodstuff, while it has also been reported from France as a suitable fodder for sheep[1].

The analytical results (mean percentages) from air-dried samples of furze growing on waste land in County Cork during the past year are as follows: moisture, 18·4; crude protein, 10·2; fibre, 26·6; fat, 1·2; nitrogen-free extract, 41 ; inorganic matter, 2·6.

No previous results are available on the carotene content of the green matter (spines) of furze and its seasonal variation, which are now reported. The following procedure has been followed in making the determinations on fresh plant material.

The furze bushes were collected in the mornings; the green, prickly spines were taken for analysis and the main woody portion of the plant discarded. The spines were chopped as soon as possible after picking. Representative samples were blanched for 1 min. in boiling water[2] and stored in a frozen condition when analysis was not immediately undertaken. Losses of carotene of up to 15 per cent were recorded when unblanched samples were analysed after 1 hr. storage. The procedure also facilitated extraction of the pigments.

The furze samples were treated with a 3 : 2 mixture of acetone–petroleum ether (boiling point, 40–60° C.) for 2 min. in a high-speed 'blendor' fitted with a small baffle-plate[3]. Calcium carbonate, just sufficient to neutralize plant acids, was added[4]. The extract was filtered, the entire process repeated twice more and acetone washed from the bulked solvent solution with water. Three processings were found to be sufficient as analysis of residues yielded no pigments.

The petroleum ether solutions were chromatographed on 10 cm. × 1·5 cm. columns of either, (1) a mixture of equal parts of magnesium oxide ('Sea Sorb 43' Fischer) and 'Hyflo-Super Cel' Johns-Manville[5], or (ii) alumina[6]. In both cases the columns were topped by a 2-cm. layer of anhydrous sodium sulphate. Carotene was eluted with 4 per cent ether in petroleum ether. Elution could be followed visually and its completion readily gauged. The eluate was made up to volume and its absorption measured on a Beckman spectrophotometer (model *D.U.*). Control analyses showed quantitative recovery of carotene added to furze samples.

The variation in carotene content of furze over a year's survey is shown in Table 1.

Table 1

Month	Carotene (mgm./kgm. dry weight)	Month	Carotene (mgm./kgm. dry weight)
January	124	July	253
February	125	August	230
March	134	September	138
April	159	October	147
May	171	November	120
June	235	December	101

Separation of the carotene mixture showed that β-carotene was the main constituent, up to 95 per cent of the total.

From October to February or March—when furze is fed to stock—the average carotene content is 126 mgm./kgm., indicating that it is a very good, and freely available, source of carotene. The relatively high values during the summer months point to the possibility of using dried furze meal as a supplementary source of carotene in animal feeding.

The problem of retention of carotene in dried furze is being investigated concurrently with that of the amino-acids in the furze protein, and a detailed report will be published later.

PHYSIOLOGY

Elongation of Rat-Tail Tendon on Hydration

The extent of hydration in connective tissues is of considerable physiological importance. Water retained by mucopolysaccharides and collagen is thought to have a pronounced effect upon the mechanical functioning of the tissue[1]. The rate and extent of swelling of collagen[2] were studied in order to measure the hydration of collagen as well as to ascertain how this might be related to the degree of cross-linking of the protein. The objective of the work discussed here was to analyse the rate and extent of elongation of a dry tendon when it was immersed in solutions.

Tendons were removed from rat tails, after stripping away the skin, by the usual method of blunt dissection with a pair of pliers. They were washed three times in 50 ml. of 0·1 *M* sodium chloride solution then washed continuously with distilled water for 30 min. Within half an hour of exposure to a temperature of 22–25° C., the tendons dehydrated to a constant ratio (*W*) of weight/length. A single tendon was inserted in a 10-ml. syringe cylinder through the bore of the glass tip ; one end was immobilized by forcing a three-way adapter over the tip while the other end, 10 cm. distant, was attached to a mechanical lever system by a small 'Alligator' clip. A 70-cm. lever arm having a mechanical ratio of 20 was used to record the elongation on an electrically driven kymograph. The load on the tendon was 20 gm. throughout the entire process.

Upon the addition of water the length increased from an initial 'dry' value (L_0) to a steady-state value (L_0+L_∞) in about 1 min. At this point the water was removed and air was sucked through the cylinder. The tendon was allowed to dry for 20 min. at a constant temperature while it shortened to (L_0) with a change in length (L_∞) of 2–4 mm. A base line was then drawn on the kymograph, the elongation on hydration was restarted by adding water, and the increase in length recorded continuously until the steady-state length (L_0+L_∞) was reached. The process of elongation on hydration and contraction on dehydration could be reproduced at least 10 times without any apparent alteration in the response of the tendon.

The length – time curve for a typical hydration–elongation is shown in Fig. 1. The first derivative ($\Delta L/\Delta t$) is plotted on the same graph to show the relationship between a point of inflexion in the displacement curve and what might be a discontinuity in the velocity curve. When the first derivative was plotted against the quantity ($L_\infty - L$) a curve resulted similar to that obtained when it was plotted against *t*. When the first derivative was plotted against the quantity $(L_\infty - L)t$ a linear relationship was found :

$$dL/dt = K(L_\infty - L)t \qquad (1)$$

Here, dL/dt is the rate of change of the length of tendon during the hydration, *K* is a specific rate constant for the process, L_∞ is the maximum change in length attained, and *L* is the change in length at any particular time, *t*. Rearrangement of the terms in equation 1, followed by integration between the limits from zero to *L* in the time-interval from zero to *t*, gives equation 2 :

$$\log (L_\infty - L) = \log (L_\infty) - Kt^2/(2 \times 2{\cdot}303) \qquad (2)$$

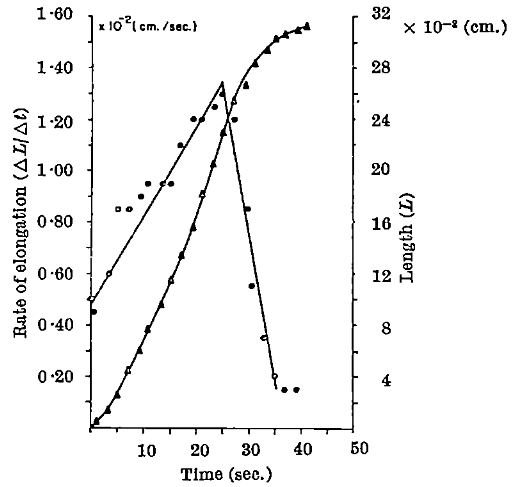

Fig. 1. The displacement (curve) and rate of displacement (straight lines) of a tendon during the hydration-elongation process. Water temperature is 23° C. and load is 20 gm.

Fig. 2 shows a family of curves plotted according to equation 2. The elongation on hydration of the same tendon was performed in water/methanol solutions where the composition was changed from 0 to 80 per cent methanol in steps of 10 per cent. The equation was obeyed satisfactorily for the elongation on hydration induced by the addition of water. However, mixed solvents produced an initial non-linear decrease in the term $\log (L_\infty - L)$ which after a short interval became linear with t^2. The extent of the deviation was minimal in water/methanol solutions but increased for other mixed solvents in the order methanol < ethanol < *iso*-propanol and propanol. The rate constant (*K*) was evaluated from the linear portion of the curve of the results with water/methanol shown in Fig. 2. Equation 3 shows a relation which was found to exist between *K* and the dielectric constant (*D*) of water/methanol solutions :

$$\log K = \log K_0 + B(D - 1)/(2D + 1) \qquad (3)$$

At concentrations of methanol greater than 40 per cent there was a positive deviation of the results indicative of specific solvent effects. It was found also that, over the region 0–80 per cent methanol, the

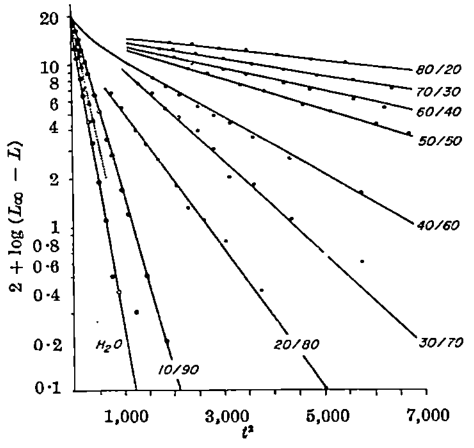

Fig. 2. The hydration-elongation of a tendon by water/methanol solutions ranging from 0 to 80 per cent methanol. The dotted line is a re-run of the water control after an 80 per cent methanol run. The initial non-linearity is shown as a curved line in an exaggerated form for the 40/60 composition

extent of elongation was related to the dielectric constant by expression 4:

$$\log (L_\infty) = \log (L_\infty)_{D=\infty} - C/D \quad (4)$$

The terms B and C, for simple reactions between ions and molecules in solution, are functions of their electrostatic interaction[3]. They might bear similar relationships to electrical interactions between charged units in the proteins of the tendon.

The rate constant (K) depends upon the diameter of the tendon and is related to it by the equation $K = K_0/W$. Since W is the ratio of weight/length, which is equivalent to $4\pi r^2 \times L \times$ density$/L$, the rate of elongation depends upon force/area, or tension.

This mechanico-chemical system offers a new method for studying the influence of the properties of solutions on a reaction between these solutions and the rat-tail tendon.

I wish to acknowledge the skilled technical assistance of Mrs. P. R. Porter and the enthusiastic support of Dr. Robert J. Boucek.

Drug-induced Immunological Tolerance

PREVIOUS work in this laboratory demonstrated that administration of a purine analogue, 6-mercaptopurine, suppressed the antibody response to a soluble antigen (human serum albumin) in rabbits[1]. It was shown that the antimetabolite could block completely the primary immune response to the purified protein antigen; its effect on the secondary response, however, was minimal[2]. It is the purpose of this communication to describe the apparent induction of immunological tolerance in adult rabbits by the use of 6-mercaptopurine.

Adult New Zealand rabbits were given one intravenous injection of human serum albumin labelled with iodine-131; the disappearance of the labelled antigen from the plasma was determined by the method of Talmage *et al.*[3]. In the experimental group a daily intramuscular injection of 6-mercaptopurine (6 mgm./kgm.) was given beginning with the day of antigen injection and continued for two weeks. Control animals received only the labelled antigen. The human serum albumin disappeared from the circulation of the control group in the three phases described previously[3]; the onset of the immune disappearance phase occurred on the eighth day, and by the tenth day radioactivity (that is, antigen) could no longer be detected in the serums taken from this group. The animals treated with 6-mercaptopurine failed to develop an immune disappearance phase, and the antigen showed a logarithmic disappearance from the serum, similar to that seen after the injection of homologous albumin, thus indicating a failure to form antibody.

About one month after the first injection of antigen, both groups of rabbits were given a second injection of human serum albumin labelled with iodine-131. In addition, both groups were given 20 mgm. unlabelled bovine γ-globulin intravenously. No further 6-mercaptopurine was given. The control group developed a typical secondary response to human serum albumin (Table 1) and precipitating antibodies to human serum albumin and bovine γ-globulin appeared in their serums. The drug-treated group again showed a normal or logarithmic disappearance of labelled human serum albumin without any evidence of antibody formation to this antigen. Precipitating antibodies to bovine γ-globulin, however, were present in their serums.

Table 1. ANTIBODY LEVELS IN DRUG-INDUCED IMMUNOLOGICAL TOLERANCE (μGM. N/ML. SERUM)

		Day of experiment		
		14	48	80
Controls	Anti-human serum albumin	62	256	354
	Anti-bovine γ-globulin	—	107	288
Tolerant	Anti-human serum albumin	0	0	0
	Anti-bovine γ-globulin	—	94	242

About one month following the second injection of antigens, both groups were given a third injection of labelled human serum albumin together with a second injection of unlabelled bovine γ-globulin. Again, no 6-mercaptopurine was given. Both groups developed typical secondary responses to bovine γ-globulin. The human serum albumin was rapidly removed from the circulation of the control group, indicating the presence of humoral antibody to human serum albumin at the time of the third injection of that antigen. The group treated with the drug, however, again showed no evidence of anti-human serum albumin formation, as determined by the logarithmic disappearance of the labelled serum from the circulation, and by negative precipitin tests.

The term 'actively acquired tolerance', first used by Billingham, Brent and Medawar[4], was defined as "an induced, specific, central failure of immunological response brought about by an exposure of animals to antigenic stimuli *before maturation of the faculty of immunological response*" (italics ours). Tolerance of this type to homografted tissues and organs as well as to simpler antigens has been induced in laboratory animals by many workers[5]. In all such experiments, this has been carried out in the newly born or immature animal. The mechanism of this phenomenon is obscure; but the results of the present study indicate that the fœtal state is not essential for its induction. As a working hypothesis, we propose that the metabolic activity provoked in antibody-forming cells by antigenic substances, in addition to providing

Incorporation of 5-Iodouracil labelled with Iodine-131 into the Deoxyribonucleic Acid of Human Leukæmic Leucocytes following *in vivo* Administration of 5-Iododeoxyuridine labelled with Iodine-131

THE extensive introduction under cell culture conditions of 5-bromodeoxyuridine and 5-iododeoxyuridine into the deoxyribonucleic acid of a cell strain derived from a human tumour was recently reported[1,2]. Prusoff *et al.* and Mathias and Fischer[3-6] have recently reported *in vitro* and *in vivo* animal studies with 5-iododeoxyuridine. *In vivo* studies in this laboratory have been oriented towards possible uses of labelled 5-iododeoxyuridine in the investigation of nucleic acid metabolism of human leukæmic leucocytes as well as other tissues in which cell proliferation is extensive.

Experiments in animals showed that the labelled 5-iododeoxyuridine was incorporated to the extent of 0·5–1 per cent into the deoxyribonucleic acid fraction of intestine and tumour of rats bearing 7-day *H.S.* No. 1 and *H.Ep.* No. 3 human tumour transplants[7]. Toxic effects were not observed following daily administration of 5-iododeoxyuridine at 33 mgm./kgm. for one week in the mouse and two doses at 6·6 mgm./kgm. to a dog on successive days.

The incorporation of the labelled iodouracil moiety into the deoxyribonucleic acid of circulating leucocytes was measured following intravenous administration of 0·62 mc. labelled 5-iododeoxyuridine (9·6 mgm.) to a 44-year old, 85-kgm. woman with previously untreated chronic granulocytic leukæmia and enlarged spleen and liver (Table 1). Incorporation of iodine-131 into the thyroid was prevented by repeated administration of potassium iodide. Sodium nucleates were extracted from the washed white cells in hot salt solution. Following dialysis of this extract, the ribonucleic acid was hydrolysed in alkaline solution and the ribonucleotides, after neutralization, removed by a second dialysis. The deoxyribonucleic acid was hydrolysed to deoxyribonucleosides by treating an aliquot of the resulting solution with deoxyribonuclease (0·0025*M* magnesium sulphate, *p*H 7) at 37° for 5 hr. followed by addition of snake venom phosphoesterases for an additional 5 hr. [8]. After coagulation of protein at 100°, aliquots of the supernatant were subjected to descending paper chromatography in *iso*propanol/hydrochloric acid/water. Labelled 5-iododeoxyuridine and thymidine were eluted. The activity of the former was measured using a scintillation counter and the µmol. of the latter determined by ultra-violet absorption. The incorporation of labelled 5-iododeoxyuridine into the deoxyribonucleic acid is expressed in column 2 as counts per min. (c.p.m.) labelled 5-iododeoxyuridine/µmol. thymidine. The possibility of contamination was eliminated by paper chromatographic studies which showed that the labelled 5-iododeoxyuridine could be detected only after treatment with deoxyribonuclease and snake venom phosphoesterases. The major portion of the administered radioactivity was eliminated in the urine (column 3). Essentially all the radioactivity was present in the urine as labelled iodide ion with the exception of the initial 2-hr. collection, which contained 8 per cent of the total administered radioactivity. In this sample 11 per cent of the activity was present as labelled 5-iododeoxyuridine. In a previous experiment in the human, less than 1 per cent of the administered activity was present in the stool.

Table 1. INCORPORATION OF 5-IODODEOXYURIDINE LABELLED WITH IODINE-131 INTO THE DEOXYRIBONUCLEIC ACID OF CIRCULATING WHITE CELLS

Hours after administration	Deoxyribonucleic acid : c.p.m. 5-iododeoxyuridine/micromole of thymidine	Cumulative percentage excretion of iodine-131 in urine
24		53
48	$2 \cdot 7 \times 10^2$	67
120	$4 \cdot 9 \times 10^2$	72·1
168	$2 \cdot 0 \times 10^2$	72·4

The results at 120 hr. indicate that at least 1 per cent of the administered radioactivity was incorporated into the deoxyribonucleic acid of the leucocytes. This is based on a white cell count of $2 \cdot 5 \times 10^5$/mm.^{3} and the following assumed values: 6 l. estimated blood volume, 7×10^{-9} mgm. deoxyribonucleic acid/cell—corresponding to $0 \cdot 6 \times 10^{-8}$ µmol. thymidine/cell. Since the circulating cells represent only a portion of the total body leucocytes, the extent of incorporation into the latter is estimated at several times the 1 per cent value calculated for the former.

Hamilton has used radiocarbon-labelled precursors of nucleic acid bases to study nucleic acid turnover in human leukæmic cells[9,10]. Since labelled 5-iododeoxyuridine is an analogue of thymidine, its incorporation into leucocyte deoxyribonucleic acid as a function of time after administration may also yield useful information concerning nucleic acid metabolism. The short half-life (8·0 days) of iodine-131 relative to radiocarbon and tritium may be of advantage in certain studies in the human.

In an attempt to evaluate differential energy absorption in white blood cells as compared with whole blood, the iodine-131 activity of plasma, red blood cells and white blood cells was determined over a 12-day period. The concentration of iodine-131 in white blood cells was greater than that in red blood cells and plasma during this period with a maximum factor of 40 on the sixth day. By integrating the areas under the curves for each of these fractions, estimates of radiation delivered to packed white blood cells and whole blood were made. The β-radiation for packed white blood cells and whole blood was 0·94 and 0·23 rad/mc. of dose respectively. The γ-radiation affecting the whole body was calculated from the body retention curve, assuming that 40 per cent of the γ-ray energy was absorbed in the body. This added 0·35 rad/mc. In this way, the total radiation absorbed in packed white blood cells was estimated to be 2·2 times that of whole blood. In so far as radiation conditions for packed white blood cells can simulate that for leukæmic infiltrates, this would be a favourable factor in consideration of possible radiotherapeutic applications[11].

Counting at skin-contact was carried out with a scintillation crystal at intervals for two weeks after administration of 5-iododeoxyuridine. The splenic area yielded a higher count than any other. At 6 days the difference between spleen and mid-thigh area was maximal and the organ-thigh ratio was 27 for spleen, 11 for liver, and 6 for cæcum and urinary bladder.

The dependence of the extent of incorporation of iodine-131 into the deoxyribonucleic acid of rapidly proliferating tissues on the mode of 5-iododeoxyuridine administration is under investigation. Measurement of differential energy absorption in a number of tissues

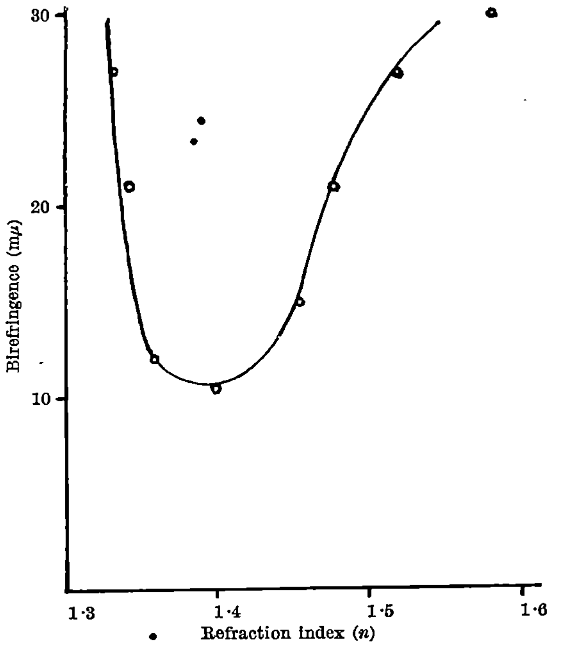

Fig. 2. Birefringence of a single lamella as a function of the refraction index of the embedding medium

curve does not decline to zero even at the point of its minimum ($n = 1{\cdot}4$). This rest (crystalline) birefringence indicates that the intralamellar micelles themselves are birefringent, that is to say, the polypeptide chains are oriented inside the micelles. The positiveness of the rest birefringence proves the longitudinal orientation of these chains.

According to our investigations, the highly specialized function of the postsynaptic membrane is rendered possible by a highly organized and at the same time very labile structure. Details concerning the submicroscopical pattern of other synaptical structures will be reported later.

5-Hydroxytryptamine in Blood during Experimental Traumatic Shock in Rats

It has been shown that the level of histamine in blood increases very much during experimental traumatic shock in rats[1]. Evidence has been presented that body 5-hydroxytryptamine (5-HT) might be influenced by the same factors as histamine[2–4]. We therefore investigated blood-levels of 5-hydroxytryptamine during experimental traumatic shock in rats.

Adrenalectomized white rats were subject to shock by limb ischæmia[5]. Rubber tourniquets were applied on both hind legs for 2 hr.; 45 min. later, when the signs of the shock became evident, the animals were killed and blood samples taken. 5-Hydroxytryptamine was extracted with 4 volumes of acetone for 24 hr. and determined on Vane's isolated rat fundus preparation[6]. The results are shown in Table 1. During shock, the blood-level of 5-hydroxytryptamine was found to be approximately four times as great as the normal value ($P < 0{\cdot}001$). Table 1 shows that the level of 5-hydroxytryptamine in the blood decreased in adrenalectomized control animals as compared with that found in normal rats (for which the values obtained were in good agreement with those found by other authors[7]). This indicates that adrenalectomy might influence blood-levels of 5-hydroxytryptamine.

Table 1. 5-Hydroxytryptamine in Rat Blood

	(1) Controls, normal	(2) Controls, adrenalectomized	(3) Traumatic shock adrenalectomized	P
5-HT (μgm./ml.) (mean ± *S.E.* of the mean)	0·276 ± 0·050	0·095 ± 0·010	0·371 ± 0·052	3 : 2 <0·001

The mechanism by which the level of 5-hydroxytryptamine in blood is raised during traumatic experimental shock is unknown. It is possible that some toxin from the ischæmic limb releases this substance. Hæmoconcentration, which ensues during shock with the increased number of blood platelets, could not significantly influence blood-levels of 5-hydroxytryptamine, since, while hæmoconcentration amounted to 130 per cent, the level of 5-hydroxytryptamine in the blood was increased to 400 per cent.

As to the significance of the elevation of blood-level of 5-hydroxytryptamine during experimental traumatic shock, it should be pointed out that this substance was found to be released from blood platelets during anaphylactic shock in rabbits[8], but the signs of this shock in the guinea pig were found not to be causally related to 5-hydroxytryptamine[9]. On the other hand, evidence exists that the anaphylactoid reaction in rats is mediated chiefly through the release of 5-hydroxytryptamine[10,11]. It is not possible as yet to say whether the increase of 5-hydroxytryptamine in the blood which occurs during experimental traumatic shock is causally related to the appearance of signs of this condition. However, it should be noted in this connexion that 5-hydroxytryptamine was found, like histamine, to increase the permeability of blood vessels[3,4].

The mechanism and the possible causal relation between the elevation of 5-hydroxytryptamine in the blood and the signs of the experimental traumatic shock are being investigated further.

Temperature Control of Physiological Dwarfing in Peach Seedlings

One of the key problems in germination physiology is the mechanism of embryo 'dormancy' or rest. One aspect of this problem is the physiological dwarfing which has been reported to occur in the seedlings of woody plants, especially of such commercial fruits as peaches. These seeds normally require an extended period of low-temperature after-ripening to permit germination. However, if the seed-coat is removed from non-after-ripened seeds germination occurs, but the shoots of such plants are abnormal with telescoped internodes and leaves which may be deformed or sometimes reduced to a rosette of white, scale-like appendages[1,2]; the exact symptoms are a varietal characteristic[3]. Low-temperature after-ripening of the seed or seedling is commonly reported to be essential to produce a normal plant.

The symptoms of physiological dwarfing in seedlings are similar to those shown by buds of trees forced after insufficient chilling. Several authors have therefore suggested[1,4,5] that the mechanisms of physiological dwarfing and the rest period in buds may be the same. In view of this similarity, and a growing body of evidence that the rest period is the result of the action of chemical inhibitors[6], several anomalous features of this phenomenon should be recognized. In the first place, dwarf seedlings have been reported to remain growing but dwarfed for as long as ten years[2], a period inconsistent with the known stability of compounds in biological systems. Secondly, the dwarfing symptoms are restricted to the leaves and stem produced directly by the epicotyl apex[1,3]; branches formed are always normal. Such precise anatomical localization is difficult to correlate with an inhibitor molecule of sufficiently small size to be chromatographed and detected in an auxin analysis system.

Table 1. Effect of Germination Temperature on the Development of Dwarfing Symptoms in Elberta Peach Seedlings from Non-after-ripened Seeds

	Germination in light			Germination in dark		
	19° C.	23° C.	27° C.	19° C.	23° C.	27° C.
Average height (cm.)	17·4	16·8	15·7	17·7	17·7	15·0
Average number of nodes per plant	18·5	16·8	15·2	17·4	18·9	14·6
Average number of nodes with abnormal leaves	0	0·8	5·5	0·7	1·7	7·1
Relative severity of dwarfing (0–4)	0	0·3	2·2	0·6	0·9	3·7

Recently we have discovered a third anomaly: physiological dwarfing is not an obligatory state in the development of a seedling from a non-after-ripened seed. Such seedlings may be either dwarf or normal; the expression, or failure thereof, of the dwarfing character is a function of the temperature to which the seed is exposed during the first few days of germination. The temperature-range for this effect is extremely small, approximately 4° C., and lies within the range of 'normal' germination temperatures.

Results of a typical experiment showing this temperature effect are presented in Table 1. In this experiment, seeds of *Prunus persica* Sieb. and Zucc. var. Elberta were sterilized by immersion for 10 min. in a 5 per cent suspension of 'Pittchlor' (Columbia, Southern Chemical Corp.), rinsed, and allowed to imbibe in the dark at 25° C. for 24 hr. The seed-coat and endosperm for about one-third the length of the seed at the hypocotyl end were excised aseptically and the seeds germinated, approximately ten in a 15-cm. Petri dish. Three germination temperatures were used. At each temperature one dish was exposed to continuous illumination 70 cm. from 40-watt standard cool white fluorescent tubes on 2-in. centres with 20 per cent added incandescent wattage. A dark control at each temperature was obtained by wrapping a dish in black polyethylene. To distinguish between light and temperature effects, the dishes rested in stainless steel trays immersed in constant-temperature water baths adjusted to give the desired seed temperature. This was necessary since high-intensity fluorescent lights produce sufficient heat to raise the level at the germinating surface considerably above ambient temperature unless special precautions are taken. After germination for seven days, the seedlings were planted in coarse white sand, watered daily with a mineral nutrient solution, and grown under the fluorescent lights described above on a 16-hr. day with day temperature of 27° C. and night temperature of 22° C. After a growing period of 5 weeks the height of the plants was measured and the total number of nodes counted, including nodes with scale leaves (germination in peach is hypogeal). In Elberta peaches grown under these conditions, dwarfing is primarily shown by distorted leaves which are abnormally wide but short and twisted as a result of the failure of midrib elongation. Severity of dwarfing was scored in two ways: (1) on an arbitrary scale of 0–4 based on a visual estimate of degree of abnormality; (2) by counting the number of nodes with abnormal leaves.

From the results, it is clear that there is little if any difference between seedlings germinated in the light and those germinated in the dark. Germination at the higher temperatures results in a slight reduction in height of plant and number of nodes. The major effect of temperature is on the development of dwarfing symptoms. At 19° C. all plants were essentially normal; at 27° C. they were all severely dwarfed. At 23° C. only a few plants showed dwarfing symptoms and few of these were severe. Thus the effective range for the development of dwarfing symptoms is approximately 4 deg. C., between 23° and 27° C. The effective time lies within approximately the first week of germination, since subsequent growth of all plants was at the same temperature.

Thus far we have observed this response in only one peach variety; it is essential to determine whether it is of general occurrence. If dwarfing is temperature-controlled in a number of varieties and species, then immediate practical applications to fruit tree breeding will be possible. The major importance of this observation, however, may lie in suggesting possible new explanations for the mechanism of the rest period. We are therefore continuing the investigation.

PATHOLOGY

Changes in Specificity and Electrophoretic Mobility of the Precipitating Antibodies present in the Serum of Cattle recovering from Foot-and-Mouth Disease

Graves[1] has shown by agar gel diffusion tests that quantitative differences exist among three different field samples (Channel Island, Ven. 1 and *M*.11) belonging to the same immunological type (Vallée O) of foot-and-mouth disease virus. He noticed, however, that these sub-type differences could not be clearly shown when early convalescent cattle serum (7–14 days) was used for the tests. This was due to the almost equal reaction of the immune serum with the heterologous as well as the homologous virus sub-type. During an examination of the nature of this cross-reaction by immunoelectrophoresis some interesting observations have been made regarding the mobility of the antibodies present in the sera during early convalescence. Cattle sera collected 7, 14 and 21 days after infection with the Channel Island sub-type of the virus were separated electrophoretically in agar by the method of Williams and Grabar[2]. The separated serum proteins were then allowed to diffuse towards the homologous Channel Island virus on one side or the heterologous sub-type *M*.11 on the other. The 7-day convalescent serum gave a precipitin line with both sub-types of the virus whereas the 14 and 21 days sera precipitated only with the homologous Channel Island virus (Fig. 1). In addition to this cross-reaction it was observed that the precipitin lines formed by the 14 and 21 days sera were longer and nearer to the cathode than those formed by the 7 day serum.

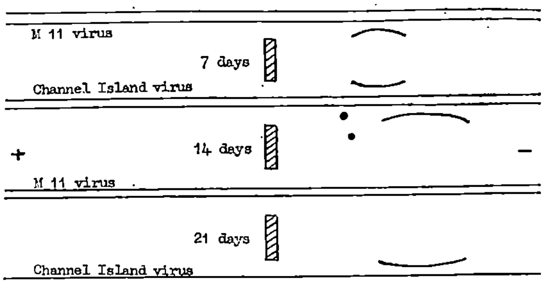

Fig. 1. Immunoelectrophoresis of convalescent sera taken 7, 14 and 21 days after infection with the Channel Island strain of the virus

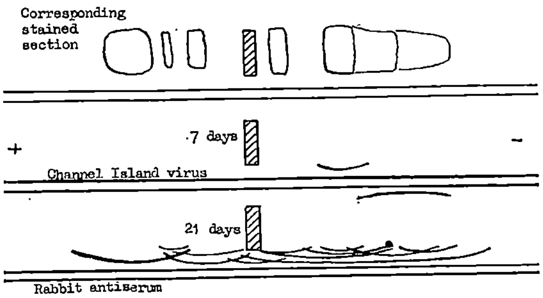

Fig. 2. Immunoelectrophoresis of convalescent sera from cattle after infection with the Channel Island strain of the virus. The positions of the precipitin bands obtained by diffusing the separated proteins towards the homologous virus and rabbit antiserum are compared

In view of this marked difference in mobility it appeared of interest to examine further the nature of the antibodies. The 7 and 21 days sera, following electrophoresis in agar, were allowed to diffuse towards rabbit anti-bovine serum and the positions of the precipitin bands compared with those obtained by diffusion towards the homologous virus. The results of such an experiment are shown in Fig. 2. It appears, on this evidence, that the precipitating antibody present in the 7-day convalescent serum corresponds to a β-type globulin. The precipitin bands obtained when the 7 and 21 days sera are allowed to diffuse from adjacent cups towards the homologous virus do not cross, however, indicating that the antibodies are identical. In addition, a mixture of the 7 and 21 day sera gives one continuous line when examined by immunoelectrophoresis. It may be, therefore, that the antibodies present in both the 7 and 21 days sera are γ-globulins of different electrophoretic mobilities.

Some further evidence has been obtained of the different physical properties of the antibodies present in the two sera. When the 7-days serum, dialysed against 0·01 *M* phosphate *p*H 7·6, is subjected to chromatography on *DEAE*-cellulose in equilibrium with the same buffer solution no virus-neutralizing activity is found in the eluate although complete recovery of this activity can be achieved by elution with 0·05 *M* phosphate *p*H 4·7. On the other hand when the 21-days serum is subjected to chromatography under the same conditions a considerable proportion (more than 50 per cent) of the neutralizing activity initially present in the serum is obtained in the 0·01 *M* phosphate fraction. It is evident that differences exist in the antibodies present in the two sera and these differences are being examined in more detail.

We wish to thank Dr. P. Grabar for his interest in this work and Mr. B. Cartwright for carrying out the serum fractionations.

Response of Newly Born Mice to a Chemical Carcinogen

Many recent reports record that certain leukæmias and malignant lymphomas can be transmitted to newly born mice using cell-free extracts of tumour tissues[1,2]. Under certain conditions, cell-free extracts of leukæmic organs also produced parotid gland tumours, sarcomas and other neoplasms[3-5]. Tissue culture extracts and extracts of tumour tissues[6-10] have given rise to leukæmias and other tumours in rats and hamsters, following injection into the newly born animal.

Since all these studies have made use of newly born animals, it seemed to us that general studies of the pathological responses of the newly born animals were of considerable importance. We have investigated the effects of certain chemical carcinogens in this same biological system. This communication reports the effects of small doses of the purified carcinogenic hydrocarbon, 9,10-dimethyl-1,2-benzanthracene, administered subcutaneously as a colloidal suspension to newly born Swiss mice. The Swiss mice were originally obtained from the Roscoe B. Jackson Memorial Laboratory, Bar Harbor, Maine, and have been bred at random in this laboratory for the past nine years. The incidence of tumours occurring in these animals has been carefully followed in many untreated controls during this time; malignant lymphomas of different types have been found in 4 per cent of animals of more than one year of age but have not been seen prior to this time. A slightly higher incidence of malignant lymphomas (6 per cent) has been noted following a single dose of 9,10-dimethyl-1,2-benzanthracene given by various routes of administration to animals 8–10 weeks old. The earliest lymphomas seen in these animals occurred at 42 weeks of age.

In the present experiment 25 newly born Swiss male and female mice, less than 12 hr. of age, were given a single subcutaneous injection of 30 μgm. 9,10-dimethyl-1,2-benzanthracene as a colloidal suspension. The suspension was prepared by the rapid addition of 9,10-dimethyl-1,2-benzanthracene, dissolved in acetone to 1 per cent aqueous gelatin, kept at 56° C. in a water-bath. The acetone was then removed by slowly bubbling nitrogen through the suspension. Newly born mice were injected subcutaneously in the interscapular region (tuberculin syringe, 26 gauge needle) with 0·015 ml. of the suspension, containing 30 μgm. 9,10-dimethyl-1,2-benzanthracene. The first animal was killed when moribund at the eleventh week from birth and showed a marked enlargement of the thymus which occupied a large part of the chest cavity, compressing the lungs. The spleen and peripheral lymph nodes appeared normal in size and colour. Three more animals were killed when moribund at the thirteenth week; one showed a marked enlargement of the thymus, the lymph nodes and spleen; the other two had an enlarged thymus and multiple lung adenomas less than 1 mm. diameter. Four additional mice, killed at the sixteenth, eighteenth and twenty-fourth weeks, all had enlargement of the thymus, lymph nodes, spleen and multiple lung adenomas. Histologically, these tumours are malignant lymphomas of the stem-cell type with early lymphocytic differentiation. Microscopic infiltrations of lungs, kidneys, skeletal muscles, spleen, lymph nodes, salivary glands and bone marrow were found; but not all these organs were involved in every animal. Thus, eight mice of a group of 25 have developed lymphomas in the short period of 11–24 weeks, at an average age of 15·3 weeks following injection (an incidence of 32 per cent). Control mice were given injections of a similar amount of colloid only; all survive and no tumours have occurred so far.

The finding that polycyclic hydrocarbon carcinogens can give rise to or enhance leukæmia has been reported many times using different strains of mice[11-14]. The present study differs from prior investigations in that only a single, low dose of carcinogen has given rise to a high incidence of malignant lymphoma rapidly in a relatively insusceptible mouse. It is emphasized, from this finding, that the development of this disease is dependent, to a great extent, upon factors inherent to the animals at this stage of development. The character of the response encountered in newly born mice with cell-free filtrates should be viewed not only in terms of virus concepts but also as a response of a sensitive biological system to carcinogenesis.

Complement Fixation with Tissue Culture and Liver Antigens of Mouse Hepatitis

HOST-SPECIFIC viruses associated with hepatitis of duck[1], dog[2], mouse[3–6], and man[7] have been described. The agents of duck[8], dog[9] and mouse[10,11] hepatitis have been propagated in tissue culture. Complement-fixing antigens have been prepared from infected livers of mouse[12] and dog[13]. However, studies on propagation and serology of human hepatitis viruses have as yet yielded equivocal results[14]. By means of virus-neutralization tests in mice, Gledhill *et al.*[15] noted an antigenic relationship among strains of murine hepatitis virus. They stated that *JHM*, Nelson, and *MHV* strains probably form a related group of viruses.

This report describes a complement-fixation test with liver antigens in which a relationship was noted between Gledhill's[16] *MHV*-1 and Nelson's[17] *PRI* mouse hepatitis strains. In addition, complement-fixing antigen was demonstrated in serially passaged tissue cultures of *MHV*-1. Tissue cultures showed no definite cytopathogenic effect but were infective for newly born mice.

The complement-fixing procedure used was essentially that described by Bengtson[18]: 0·2 ml. quantities each of antigen dilutions, serum (inactivated as a 1 : 10 dilution in saline at 61° C. for 20 min.), and complement (2 units) were used; after incubation overnight at 4° C., the hæmolytic system was added; complement fixation was determined visually after subsequent incubation at 37° C. for 30 min.

Complement-fixing antigens were prepared from liver homogenates of suckling mice infected with *MHV*-1 and of weanling mice (8–10 gm.) infected with *PRI* virus. Whole cultures of serially passaged *MHV*-1 in mouse kidney explants[11] were also used as complement-fixing antigens. Later experiments indicated that nutrient fluids alone contained this complement-fixing antigen. Control antigens were prepared from liver homogenates of normal weanling and suckling mice and from uninoculated tissue cultures. Each antigen preparation was centrifuged at 40,000*g* for 1 hr. at 4° C. to eliminate sedimentable non-specific complement-fixing factors which occurred occasionally with some pools of control material centrifuged at lower speeds.

Tissue culture and liver preparations containing *MHV*-1 were assayed for infectivity in newly born Swiss mice[11]. Titres of 8 different *MHV*-1 liver pools had *ID*50 end-points of $10^{-3\cdot 0}$ to $10^{-3\cdot 5}$/0·05 ml. of inoculum. Ten serially passaged tissue cultures of *MHV*-1 yielded ID50 end-points from $10^{-4\cdot 1}$ to $10^{-5\cdot 2}$ (Table 2). The *PRI* liver homogenates had *ID*50 end-points from $10^{-3\cdot 2}$ to $10^{-3\cdot 6}$/0·1 ml. inoculum when assayed in weanling Swiss mice (8–10 gm.).

Table 2. COMPARISON OF INFECTIVITY AND COMPLEMENT-FIXATION TITRES OF SERIALLY PASSAGED TISSUE CULTURES OF *MHV*-1

Passage No.	Dilution of original virus	Infectivity titre* −log *ID*50		Complement-fixing titre reciprocal of antigen dilution			
		0 hr.	96 hr.	0	2	4	8
1	10^{1}	2·4	4·8	*NT*†	*NT*	*NT*	*NT*
2	10^{3}	3·0	4·6	*NT*	*NT*	*NT*	*NT*
3	10^{4}	2·5	4·8	++++	+++	−	−
4	10^{5}	3·8	5·2	++++	++++	−	−
5	10^{7}	1·9	4·4	+	−	−	−
6	10^{8}	*NT*	4·7	++++	+++	−	−
7	10^{9}	3·7	4·1	++++	++++	++++	−
8	10^{10}	3·5	4·8	++++	−	−	−
9	10^{11}	3·6	4·2	*NT*	++++	++++	−
10	10^{12}	2·7	4·3	++++	++++	−	−

* See ref. 11. † Not tested.

Antisera were prepared in adult Swiss mice by intramulscular injection of extracts of either normal or infected mouse liver. Inocula were combined with adjuvant (mineral oil/'Arlacel'/antigen, 1·0 ml. : 0·1 ml. : 1·0 ml., respectively) and two injections of 0·2 ml. each of the mixture were given 14 days apart. Groups of 40–60 immunized mice were bled 14 days later and their sera were pooled. Control sera were obtained from untreated mice.

Results of box titration tests showed cross complement-fixing reactions between *MHV*-1 and *PRI* virus (Table 1). Normal liver antigen did not fix complement in the lowest dilutions of serum and antigen tested. However, 1 out of 10 supposedly 'normal' serum pools fixed complement in the presence of *MHV*-1 and of *PRI* liver preparations. As viral agents causing hepatitis in mice have appeared 'spontaneously' during the course of studies on enteric disease of the suckling mouse[6], human viral hepatitis[3,19] and mouse leukæmia[5,17], it is possible that some donors to this positive 'normal' serum pool had in fact been infected with a murine hepatitis virus related to *MHV*-1 or *PRI*.

Antigens processed from *MHV*-1-infected, kidney explant tissue cultures fixed complement in the presence of *MHV*-1 immune serum (Table 2). All serum pools were diluted 1 : 10 in saline and inactivated (61° C. for 20 min.) prior to use. Control serums and antigens were negative in this system. It appears that complement-fixing titres obtained with tissue-culture antigens were somewhat lower than those obtained with liver antigens. Of 18 additional mouse-kidney tissue-culture antigens tested, infectivity titres ranged from *ID*50 $10^{-1\cdot 9}$ to $10^{-5\cdot 2}$ and complement-fixing titres from 1 : 0 to 1 : 8. A relation-

Table 1. CROSS-REACTIONS BETWEEN COMPLEMENT-FIXING ANTIGENS OF *MHV*-1 AND *PRI* MOUSE HEPATITIS VIRUSES

			Liver antigen – reciprocal of dilution									
			MHV-1					*PRI*				
			4	8	12	16	20	4	8	12	16	20
Immune serum – reciprocal of dilution	*MHV*–1	10	++++	++++	++++	++++	+	++++	++++	++++	++	−
		20	++++	++++	+++	++	−	++++	++++	++++	−	−
		40	++++	++++	++	−	−	++++	++++	+++	−	−
		60	++++	++	−	−	−	++++	++++	+	−	−
		80	++++	−	−	−	−	++++	++++	−	−	−
	PRI	10	++++	+++	−	−	−	++++	++++	+	−	−
		20	+++	−	−	−	−	++++	+++	−	−	−
		40	++	−	−	−	−	++++	++	−	−	−
		60	+	−	−	−	−	++++	+	−	−	−
		80	−	−	−	−	−	++++	+	−	−	−

ship was not noted between complement-fixing and infectivity titres in these tests.

A relationship was demonstrated between the *MHV*-1 and *PRI* murine hepatitis strains by complement-fixation tests. Specific antigen was obtained from serially passaged, *MHV*-1-infected, mouse-kidney tissue cultures which fixed complement in the presence of immune serum prepared in mice with extracts of *MHV*-1-infected liver in adjuvant.

This investigation was supported by the James W. McLaughlin Fellowship Fund awarded to the senior author.

Incorporation of Thymidine labelled with Tritium by Circulating Cells of Infectious Mononucleosis

CONSIDERABLE uncertainty exists about the origin and the identity of the cells of infectious mononucleosis. They have been described as atypical lymphocytes, as monocytes, as reticular-endothelial cells developing towards a lymphomonocyte or even a plasma cell. Most hæmatologists[1,2], however, regard them as mature cells, even though they do vary greatly in size and shape.

Useful information on this subject could certainly be obtained by a functional study of these cells. Autoradiography provides a powerful tool for investigation at a cellular level. Moreover, the availability of compounds labelled with tritium has greatly improved the resolution of this method. Thymidine-^{3}H is known to be a specific precursor of deoxyribonucleic acid; therefore, its incorporation into cell deoxyribonucleic acid is evidence of active deoxyribonucleic acid synthesis, possibly preparatory to later mitosis.

Incorporation of thymidine-^{3}H has been investigated in the peripheral blood of three cases of infectious mononucleosis and of two normal subjects. In infectious mononucleosis incorporation has been followed during the various stages of the disease up to complete recovery. All cases showed a complete clinical picture, a characteristic hæmatological pattern and a highly positive Paul–Bunnel test.

Blood was withdrawn from the antecubital vein and 2 ml. of a 5 per cent dextran solution (molecular weight 150,000) was added to 8 ml. of citrated blood. After 20 min. the supernatant was pipetted into a test-tube; the white cells were washed twice in normal saline with low-speed centrifugation and then resuspended in Eagle's medium. This procedure was carried out under sterile conditions. Thymidine-^{3}H with a specific activity of 390 mc./mM was then added to a final dilution of 5 μc./ml. Incubations were in a water-bath at 37° C.; samples of cells were withdrawn after 2, 4 and 6 hr. and smears were made on gelatin-coated slides. The smears were fixed in Carnoy's solution, and, after several washings in distilled water, stripping films (Kodak *AR*-10) were placed over the slides according to the method described by Pelc[3]. The films were developed after ten days exposure and smears stained through the stripping film with May–Grünwald–Giemsa. For each slide 4,000 cells were counted to determine the amount of labelling.

The percentage of labelled cells detected in normal individuals corresponded strictly to that observed by Bond *et al.*[4], that is, 0·06 per cent referred to the number of total white cells; labelled cells were all large lymphocytes or monocytes. In cells from patients affected by infectious mononucleosis considerably higher values were observed (Table 1); in the first stage of the disease, for example, the mean percentage of labelled cells, after 2 hr. incubation, was 4·44, that is, more than thirty times the value for normal blood. This percentage decreased progressively during the course of the disease and, with the complete recovery, reached the normal value. In the first stage of the disease only the percentage of labelled cells increased linearly with the time of incubation, from 4·44 (second hour) to 10·5 per cent (sixth hour). This linearity was no longer detectable in the later stages.

Table 1. PERCENTAGE OF LABELLED LYMPHOMONOCYTES AT DIFFERENT STAGES OF THE DISEASE (AFTER 2-HR. INCUBATION)

Stage	Cases			Mean value	σ ±
	1	2	3		
1	3·8	4·3	5·2	4·44	0·57
2	1·1	2·1	1·4	1·53	0·41
3	0·30	0·30	0·15	0·25	0·12
4	0·066	0·075	0·048	0·063	0·011

Stages: 1, Acute phase of the disease; 2, early improvement; 3, full improvement; 4, complete recovery.

Our results clearly show that in infectious mononucleosis the cells of the peripheral blood have a greater tendency to synthesize deoxyribonucleic acid than normal lymphomonocytes. This synthesis may be preparatory to subsequent mitosis, though this cannot be considered as direct evidence of mitosis. No mitotic figures were observed in any of the slides we examined. Mitosis in the peripheral blood of infectious mononucleosis patients has been only occasionally reported[5-7].

The incorporation of deoxyribonucleic acid precursors by bone marrow cells has been used to calculate the mitotic cycle of these cells[8]; in our case, however, the degree of incorporation during the period of incubation does not permit such a study because it is not certain that all mononuclear cells of the peripheral blood will undergo mitosis; moreover, as demonstrated by Painter[9], the radiobiological effect of thymidine-^{3}H incorporated in the chromosomes may, in *in vitro* experiments, affect the proliferative activity of the cells.

The most important fact shown by this investigation is that the cells of infectious mononucleosis behave in a completely different way from the lymphomonocytes of normal peripheral blood with respect to deoxyribonucleic acid synthesis. It is therefore reasonable to consider them as totipotent cells of mesenchymal origin, which actively proliferate in the organs and easily enter the peripheral blood. As an alternative hypothesis one might suggest that the increased synthesis of deoxyribonucleic acid may indicate virus synthesis within the cells.

We wish to thank Prof. G. C. Dogliotti for his useful suggestions.

BACTERIOLOGY

Measurement of a Staphylococcal Antibody in Human Serum by a Mouse Protection Test

THE need for a better understanding of immune phenomena related to staphylococcal infections has been repeatedly emphasized[1]. In so far as humoral antibodies are concerned, a substantial amount of work has been done only with staphylococcal antitoxins. However, as pointed out by Rountree and Barbour[2], this approach has not appeared to be rewarding. It has also been suggested that anticoagulase may be an important antibody[3]; but some doubt exists as to the significance of coagulase in staphylococcal infections[4,5]. Although a promising serological procedure was developed by Rountree and Barbour[2], this method was not applied in a study of infections.

It has been postulated that one of the most significant tests of the importance of antibody is the demonstration of its protective activity in experimentally infected animals[6]. Therefore, the application of the mouse protection test described in this communication may provide a useful new approach for the study of staphylococcal immunity. In addition this procedure not only provides acceptable sensitivity but can also be used to measure the staphylococca antibody content of a given serum.

Since the mechanism of action is at present unknown for this antibody, it is described functionally as 'mouse protective antibody'. The specificity o mouse protective antibody has been established by absorption procedures, similar to those used for determining antibody specificity in human gamma globulin[7], and will be reported elsewhere. Its 'classic antibody nature is also supported by the fact that mouse protective antibody potency was unaltered by exposure to 60° C. as long as 4 hr.

In performing a mouse protective antibody assay 18–22 gm. albino Webster mice, either sex, are injected intraperitoneally with 10–20 *LD*50 of the Smith strain of *Staphylococcus aureus*. This inoculum consisting of about 10^4 cells, is derived from a 12–18 hr broth culture and is suspended in 5 per cent hog gastric mucin, using 0·5 ml./mouse. As described by Hunt and Moses[8], this dose of Smith staphylococcus will produce an acute systemic infection, lethal to 90–100 per cent of untreated mice within 24 hr Although most of these studies have involved the Smith strain, comparable activities of given serum have been obtained with other staphylococcal strains

Within 30 min. of challenge, groups of mice ar injected intraperitoneally with 0·25 ml. each o varying saline dilutions of the serum to be titrated A preliminary test is performed first with 40 mice 10 untreated controls and three groups of 10, using serum dilutions of 1 : 10, 1 : 100 and 1 : 1,000. Th five-day survival values obtained from this test ar used as a guide for setting up a definitive titration In the second assay, groups of 15–20 mice and two fold serum dilutions are employed. Usually, fou serum dilutions will suffice for obtaining surviva data ranging between 0 and 100 per cent, so that minimum total of 115 mice is required for the preliminary and definitive assays. As indicated, a five day observation period will provide final surviva results, and, in general, no more than 2 ml. of serum are required for the entire assay.

A typical set of results is given in Table 1 for given serum, illustrating the preliminary and definitive assays and the increasing protective activity (increasing amounts of serum. The survival percentages derived from the definitive assay ar employed for the estimation of mouse protectiv antibody titre, which can be expressed as the 50 pe cent protective dilution (*PD*50). A practicable mea of determining the *PD*50 with such survival data the Miller–Tainter method[9]. The *PD*50 derived fro the results shown in Table 1 is given at the botto of the table.

Table 1. REPRESENTATIVE RESULTS OF MOUSE PROTECTION TEST, PRELIMINARY AND DEFINITIVE, OF A HUMAN SERUM SPECIME

Serum dilution	Survivors/total	Survivors (per cent)
Preliminary:		
None (untreated)	0/10	0
1 : 10	10/10	100
1 : 100	9/10	90
1 : 1,000	1/10	10
Definitive:		
None (untreated)	1/20	5
1 : 100	19/20	95
1 : 200	16/20	80
1 : 400	8/20	40
1 : 800	3/20	15

50 per cent protective dilution, 1 : 350

Analyses of 50 sera from normal adults revealed *PD*50 titres ranging between 1 : 3 and 1 : 2,000. The geometric mean titre of this group was 1 : 192, as calculated by Perkins's method[10]. Limited studies have shown that persons with a chronic staphylococcal infection, furunculosis, had serum *PD*50 titres in the low range : 1 : 10 to 1 : 60. It has also been noted that, out of 54 pairs of maternal and newly born (cord) sera, 41 exhibited comparable mouse protective antibody, but 13 cord sera were substantially lower in mouse protective antibody content than were the respective mothers. This observation suggests, as noted by Rountree and Barbour[2], that in some instances there may be a placental barrier to the transmission of staphylococcal antibody to the fœtus. Studies are in progress to determine the incidence of staphylococcal infection among the newly born and their mothers with respect to their mouse protective antibody titres.

The widespread occurrence of staphylococcal mouse protective antibody in adult human sera indicates that this is a normal antibody, a characterization that was previously applied by me for staphylococcal and other bacterial mouse protective antibody in pooled human gamma globulin[11]. This conclusion has been recently substantiated by Jensen[12], who employed a qualitative agar gel precipitin method for demonstrating staphylococcal antibody in human sera.

Immunizing Properties of Insoluble Cell Material derived from *Brucella*

AN insoluble fraction was obtained by high-speed centrifugation from *Brucella suis*, after disintegration in a sonic vibrator[1]. This fraction could absorb the agglutinating and mouse protecting antibodies from *B. suis* antisera. Since similar absorptions could be carried out, although less effectively, with whole bacteria, the insoluble material was assumed to be situated on the cellular surface and tentatively regarded as part of the cell wall.

The present work was concerned with the immunizing properties of two insoluble fractions derived from *B. abortus* and *B. suis*. The starting material consisted of bacteria killed and dried with acetone, disintegrated in a 9-kc./s. Raytheon magneto-striction oscillator. The sonic extract was centrifuged in a Sorval centrifuge at 10,000 r.p.m. and the sediment freed from intact cells by differential centrifugation. Fraction 1 (*F*1) was thus obtained. Fraction 2 (*F*2) consisted of smaller particles sedimented from the supernatant fluid left from the first centrifugation, after spinning for 30 min. in a Spinco model *L* ultracentrifuge at 40,000 r.p.m. The immunizing activity of these fractions was compared in mice with that of whole cells killed and dried with acetone, following a method previously used in passive protection experiments[2]. 0·01–1 mgm. quantities were injected intra-abdominally into groups of 5–10 mice. At various times after immunization (2–14 weeks) the immune animals were challenged, together with controls, with 30,000 virulent *B. abortus* (strain 2308) cells administered intra-abdominally. 7 days later the mice were killed with ether, the spleens removed, ground with glass sand and plated on trypticase soy agar. Protection indices were calculated as the ratio of the number of *Brucellae* in the spleens of normal mice to that in the spleens of the immune mice. Higher indices were consistently obtained with the insoluble fractions and the small particle fraction (*F*2) appeared to be more effective than *F*1 (Table 1).

Table 1. IMMUNIZING ACTIVITY OF WHOLE, DRIED *Brucella* CELLS AND OF INSOLUBLE FRACTIONS DERIVED FROM THEM

Immunizing antigen	Protection indices when challenge given at weeks after immunization 2	3	6	12	14
B. abortus whole cells	270	–	30	—	8*
B. abortus Fraction 1	541	—	750	—	53*
B. suis whole cells	25	—	—	—	—
B. suis Fraction 1	222	236	—	50	—
B. suis Fraction 2	—	3,535	—	600	—

One immunizing injection was administered. Groups marked with an asterisk received 1 mgm. antigen, the others received 0·1 mgm.
—, Not done.

The higher efficiency of the insoluble fractions, as compared with whole bacteria, was evident in many other experiments not reported here.

It appears very likely, in view of their serological properties, that the insoluble fractions are cell-wall fragments of various sizes, as already stated in a previous publication[1]. Chemical and spectrophotometric determinations are in progress to confirm this assumption. Although little studied so far[3], cell-wall material has already been found a good immunizing antigen[4,5], and the present work shows it to be of promise in immunization against *Brucella*. Recent work[6,7] suggests, however, that some of the activity shown by the cell wall may be non-specific. Experiments are under way to determine to what extent the effects described above might be reproduced with non-related cell-wall material.

This is a preliminary report on an investigation carried out by one of us (J. M.) in partial fulfilment of the requirements for the Ph.D. degree of the Hebrew University—Hadassah Medical School.

BIOLOGY

Atmospheric Pollen in Relation to Land Use

THAT the present provides the key to the past is a geological commonplace, and considerable attention has been paid accordingly to the interpretation of pollen diagrams in the light of pollen analyses of recent or surface samples[1,2]. Formerly such investigations centred mainly on the composition of a fossil pollen spectrum as a reflex of its contemporary tree flora. To-day interest, more particularly in western Europe and especially in Britain, has widened to include not merely the composition of forests in prehistoric and early historic time but also the extent and character of the vegetation which, as the result of human activity or of other causes, has more and more replaced forest. A consideration of the composition of to-day's pollen rain in relation to present land use has therefore become desirable.

In the course of an atmospheric pollen census begun in 1942, and still continuing[3], pollen spectra have been obtained from some fifteen centres in Great Britain; but most of them are from inland localities in the lowlands and therefore so heavily weighted with local pollen as to be of little use as reflexes of regional (as opposed to strictly local) land use. Two complete and continuous sets of daily analyses have, however, been made for five years (1945–49) in each of two high, remote and virtually treeless localities among the Brecknockshire mountains, namely, one at Storey Arms on the Beacons road (1,400 ft.) between Merthyr Tydfil and Brecon and the other at Grwyne Fawr Reservoir (1,600 ft.) in the heart of the Black Mountains. A summary of the results of the two sets of analyses is set out in Table 1. The figures in the column headed T.T.P. (total tree pollen) indicate the total numbers of the pollen grains usually included by palæopalynologists under the heading of total tree pollen, namely, birch, pine, elm, oak, lime, alder, beech, hornbeam and ash; those in the columns headed N.T.P. (non-tree pollen) include all herbaceous pollens; other arboreal pollens than those under T.T.P., and all damaged and unidentified grains have been omitted, and the relation between N.T.P. and T.T.P. is seen to be much the same at both stations.

The kinds of pollen (listed above) that make up the T.T.P. are produced by broad-leaved woodlands and pine plantations together, while those that form the N.T.P. come very largely from cultivated land, though some (probably a relatively small proportion) come from the large area recognized as rough grazings (here almost all heavily grazed mountain land). The relevant figures for the respective types of land use have been extracted from the Forestry Commissions Census Reports[4,5] allowance being made for small woods and hedgerow trees[6] and the Ministry of Agriculture's Agricultural Statistics 1945–49 [7], respectively, and are set out in Table 2 first for Brecknockshire alone and then (since some of the pollen trapped must have come from outside that county) for Brecknockshire and five adjacent counties together (Cardiganshire being omitted as too remote).

Table 1. POLLEN DEPOSITION ON BRECKNOCKSHIRE MOUNTAINS, 1945–49

(Grains caught and identified on 5 sq. cm. of horizontal surface)

Station	Total tree pollen (T.T.P.)	Non-tree pollen (N.T.P.)	N.T.P. as percentage of T.T.P.
Grwyne Fawr (Black Mountains)	7,594	22,652	297
Storey Arms (Brecon Beacons)	9,046	27,798	310
Two stations together	16,640	50,450	303

In Table 2 the area entered as arable includes rotation grasses: rather more than one-third of this grassland, taken together with the 'permanent grass', was mown in 1947. It will be seen that whereas N.T.P. on the Brecknockshire mountains is about 300 per cent of T.T.P. (Table 1), the corresponding area of cultivation ('crops and grass') is between 420 and 630 per cent, or, say, 500 per cent, while the area of cultivated land and rough grazings together is between 1,120 and 970, or, say, 1,000 per cent, that of pollen productive woodland. Hence the pollen productivity (in T.T.P.) per unit area of woodland, as measured by pollen precipitation in an area partly fringed (at a distance here averaging 5 miles) by woods, must lie between 5/3 and 10/3 times (that is, between 166 and 333 per cent) of the pollen productivity (in N.T.P.) per unit area of non-forest land lying around the same periphery. Whether the lower or the higher figure is more nearly correct must depend on the pollen productivity of the rough grazings which immediately surround both stations and which, to judge from their botanical composition and the heavy grazing to which they are subjected, must in general be low.

The composition of the pollen rain at these two stations has been worked out in some detail. Thus, grass pollen on the Brecknockshire mountains makes up four-fifths of the N.T.P., that is, it is equivalent to say 250 per cent of the T.T.P. Dr. Verona Conway[8], in her studies of Pennine blanket peats at altitudes varying from 1,200 to 2,050 ft., recorded, in her Zone VIII (modern), grass pollen values of 15–300 per cent of T.T.P., and obtained also from surface blocks values up to 300 per cent. Having regard to the much greater disparity at present existing between woods on one hand and crops, grass and rough grazings on the other in Derbyshire (from which county most of the pollen precipitated on the southern Pennines is derived) as compared with South Wales, a much higher grass pollen figure than 300 per cent might be expected in the former area to-day. It seems likely, therefore, that, provided differential pollen destruction during fossilization can be excluded, Dr. Conway's highest figures relate to a time when deforestation was much less widespread than it is now.

Table 2. LAND USE IN AND AROUND BRECKNOCKSHIRE (ACRES)

	Woodlands productive of T.T.P.	Crops and grass				Rough grazings	Crops, grass and rough grazings together		Total land area
		Arable including rotation grasses	Permanent grass	Total	As percentage of woodlands		Total	As percentage of woodlands	
Brecknockshire	36,000	69,349	82,011	151,360	420	251,698	403,058	1,120	466,347
Six counties	238,000	646,473	860,078	1,506,551	630	798,260	2,304,811	970	2,751,772

Again, pollen of ribwort plantain (*Plantago lanceolata*, an almost invariable concomitant of agriculture from Neolithic times onwards)[9] plays an important part in analyses of pollen to-day. It is, next to grass and nettle pollen, the largest constituent of the N.T.P. precipitated on the Brecknockshire mountains, giving values (in terms of T.T.P.) of 10·6 per cent at Storey Arms, 13·2 per cent at Grwyne Fawr, and an average of 12·2 per cent for the two taken together. Godwin[10] obtained similar counts of plantain pollen (up to 10 per cent of T.T.P.) from Neolithic or post-Neolithic lake deposits on the edge of the East Anglian Breckland; the same author's analyses of peat datable between the Middle Iron Age and the middle of the Roman period in Somerset[11] gave much higher values (up to 60 per cent of T.T.P.). Since deforestation and the spread of agriculture can scarcely have been more general in Somerset around A.D. 0 that it is in South Wales to-day, the figures last quoted would seem to be due to quite local influences.

It is hoped to publish the results of this research more fully elsewhere. This work received generous aid in the form of Government grants voted by the Royal Society.

Detachment of Conidia by Cloud Droplets

IT has been found by experiment that conidia may be detached from conidiophores by the impact of minute water droplets in a moving mist or cloud. A preliminary report of this is given since it appears to be a mechanism of spore detachment which has not yet been described.

In an initial experiment, an open Petri dish of nutrient agar was held behind a culture of *Verticillium albo-atrum*, and the colony sprayed with water droplets from a simple atomizer so that some of the droplets swept the colony and were impacted on to the surface of the agar in the dish beyond. The dish was then covered with a lid and incubated. When examined, a number of *Verticillium* colonies were found among the numerous common air-borne mould fungi which developed. No *Verticillium* colonies appeared on control plates when a culture was subjected to puffs of air (with no water droplets) from the same atomizer. Spore detachment was therefore concluded to have been due to the impact of the minute water droplets.

Following this observation, pieces of grass culm and cotton thread soaked in nutrient agar were inoculated with dense spore suspensions of mould fungi and incubated at 100 per cent relative humidity. When the conidiophores were developed, the cultures were placed in air streams into which a continuous stream of water droplets was introduced when required. These droplets were in the size-range 8–210μ diameter with a modal diameter of 78μ.

Table 1. NUMBERS OF SPORES REMOVED FROM *Cladosporium* COLONIES DURING 1-MIN. EXPOSURES TO STREAMS OF AIR AND AIR-CARRYING CLOUD DROPLETS RESPECTIVELY

Colony	Air speed (m.sec.)	Spores detached by air current	Spores detached by air current plus droplets
1	0·5	350	4,800
2	0·7	200	67,000
3	2	250	51,000
4	5	3,000	18,000
5	10	4,000	32,000

In a series of experiments, each colonized stem or thread was supported across the prongs of a simple wire fork and placed before the intake orifice of a Gregory[1] spore trap. An air stream of known velocity was then drawn over the colony for 1 min., and the spores removed sucked on to the sticky surface of the slide in the trap. After changing the trap slide, the air was turned on again for another minute with cloud droplets being simultaneously directed into the stream flowing over the colony so that the conidiophores were bombarded with the water droplets carried by the moving air.

The results for *Cladosporium* are typical, and show that larger numbers of spores are detached by air currents containing minute water droplets than by air currents of the same velocity without droplets.

New Members of the British Marine Bottom Fauna

A STUDY is being made of the smaller members of the fauna of marine gravels on the sea-bed in the Plymouth area. One aspect of the results so far obtained is concerned with the array of pygmy species encountered, several of which, as might have been expected, are new to the British fauna.

A bucket of shelly gravel from near the entrance to Plymouth Sound below about 7 fathoms of water (collected by Mr. G. R. Forster during an aqua-lung dive) produced three species of Acochlidiacea, a sub-order of Gastropoda not hitherto recognized as British (though all three have been found near Heligoland). These are *Microhedyle lactea* Hertling, *Hedylopsis suecica* Odhner, and *Philinoglossa helgolandica* Hertling. These animals are shell-less and do not exceed 2 mm. in length, and are scarcely detectable if they cannot be examined alive. A specimen of the small holothurian *Leptosynapta minuta* (Becher) was also obtained from this sample: a species not on the British list, but, as I have since been informed by Dr. D. J. Crisp, discovered at Bangor by Dr. B. Swedmark in 1956.

Chief attention, however, has been given to the Eddystone shell gravel, a well-known source of *Amphioxus lanceolatus* (Pallas), and producing a macrofauna, dominated by lamellibranchs, long familiar to workers at Plymouth[1]. The position sampled is between 1 and 2 km. north-west of the Eddystone Rock, some 15 km. from the nearest mainland, and the depth of water above it is 23–28 fathoms.

This gravel also has given *Microhedyle lactea* and *Leptosynapta minuta* in small numbers. One oligochæte worm (not yet determined) and five species of mites of the family Halacaridae have been isolated. Among these mites *Scaptognathus tridens* Trouess. and *Halacarus bisculus* Viets are new to Britain according to Mr. G. O. Evans, of the British Museum (Natural History), to whom I am indebted for checking the identifications.

But the most notable feature of the Eddystone shell gravel is its rich fauna of small crustaceans, as first noticed by Prof. J. E. Harris during an unsuccessful search for young stages of *Amphioxus*. The smaller Malacostraca have been sorted from two separate major samples of gravel (using magnesium sulphate flotation technique), and so far 56 species have been listed. Of these some 20 are new to the Plymouth fauna[2] and five or six are new to science.

The many Amphipoda include a new species of *Metopa* and one of probably a new genus of Syrrhoidae, both among the more numerous species present in both major samples. (Two other new species of special interest are mentioned later.) Tanaidacea proved fairly numerous, dominated by *Typhlotanais microcheles* Sars and *Strongylurella indivisa* Hansen, both species new to Britain and rarely encountered anywhere. Among Isopoda, by far the most frequent have been *Paramunna bilobata* Sars and *Eurycope pygmaea* Sars, both well figured originally[3], but apparently the latter not previously known as British. Of special interest was the occurrence of a single example of *Microjaera anisopoda* Bocquet and Lévi[4], a particularly small blind janirid of 1·2 mm. described recently from two examples taken off Roscoff. Nothing else is known of this genus. More is known of another blind colourless genus, *Microcharon*, which is represented in the gravel by a new species, *M. harrisi* Spooner[5]. Six of the nine species of *Microcharon* so far discovered live in terrestrial ground-water in southern and eastern Europe, and two in coastal sand[6]. It is a genus belonging to the sub-family Microjanirinae, which is a typical element of the interstitial (phreatic) ground fauna, of which the bathynellids were the first to attract attention.

Two other blind 'interstitial' genera have now been found to be represented in the same shell gravel. One is a new genus of the amphipod family Bogidiellidae, so far represented by six species of *Bogidiella* from subterranean fresh water of coastal sand of southern Europe and Brazil. This is the first offshore occurrence of the family. The animal is very fragile, and only one of the fourteen specimens isolated is entire : this one shows a peculiar development of the seventh peræopod.

The remaining discovery is *Ingolfiella*, a genus which for long has stood as a separate sub-order of Amphipoda. Two specimens have so far been found, in a sample of gravel collected on March 30. The six species of this little-known genus show an extraordinary scattered distribution, ranging from the deep water of the North Atlantic (*I. abyssi* Hansen[7]) to caves in the Belgian Congo (*I. leleupi* Ruffo[8,9]). The newly found examples, the first from European seas, differ in small ways from four of the described species, but are clearly very close to *I. acherontis* Karaman from the ground-water of the Macedonian uplands (though presumably will not prove to be identical with it).

The occurrence of three phreatic genera in a marine deposit raises an interesting zoo-geographical issue. Each separately belongs to a taxon of at least sub-family status which is confined to the subsurface domain, and has no normal (that is, eyed and pigmented) representative in the surface waters. These seem to belong to a slow-breeding (and slow spreading) faunistic element which is dispersed through the water held in the rocks and deposits below the lighted surface—not confined to continents, but continuously distributed both through them and under the sea bed. This view supposes that genera arise, disperse gradually in their native medium, and evolve, irrespective of whether air, fresh water, or ocean lie above the strata they inhabit. Any aquatic group, whether marine or fresh water, is a potential ancestor to members of such a fauna.

This idea will be followed up in future work, and the descriptions of new species mentioned above, it is hoped, published in the near future.

Early Formation of Sperms in the *ey*^{2} Mutant of *Drosophila*

THE testis of the newly hatched larva of wild-type *Drosophila* contains only spermatogonia which give rise to primary spermatocytes at the beginning of the second larval instar[1,2]. The primary spermatocytes which represent the early prophase of the first meiotic division have bigger nuclei and are larger in size and lie in the posterior end of the testis. This stage in the differentiation of the testis remains unchanged throughout the rest of the larval life. More advanced stages begin to appear after the formation of the puparium, so that 20-hr. old pupæ contain fully mature sperms.

The appearance of sperms in the larval testis has been reported as of rare incidence in the wild type[3]. On the other hand, sperm bundles showed up most frequently in the larval testis of some lethal mutants with prolonged larval life[4]. However, these usually disintegrate and give rise to patches of histolysed germ tissue.

In the present investigations, it has been found that the majority of *ey*^{2} late third instar larvæ, irrespective of the type of the eyeless phenotype which the larvæ will develop, contain stages up to and including sperm bundles. In some specimens, these advanced stages have become degenerate. 3-hr.-old eyeless prepupæ, without any exception, showed fully mature sperms. This shows that *ey*^{2} specimens reach sexual maturity at least 17 hr. before the normal time.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, June 15

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 3 p.m.—Annual General Meeting.

British Society for the Philosophy of Science (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. D. Bohm : "The Interpretation of Quantum Theory".

Wednesday, June 17

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Mr. E. Knighting : "Numerical Experiments in he Integration of the Meteorological Equations of Motion" ; Mr. J. S. Sawyer : "The Introduction of the Effects of Topography into Methods of Numerical Forecasting".

University College, Department of Philosophy (in the Gustave Tuck Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. K. Ajdukiewicz (University of Warsaw) : "What do Sentences State ?"*

Wednesday, June 17—Saturday, June 27

International Plastics Exhibition (at Olympia, London).*

Thursday, June 18

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. F. C. Bawden, F.R.S. : "Viruses : Retrospect and Prospect" (Leeuwenhoek Lecture).

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. C. A. Rogers : "Coverings of n-Dimensional Space by Spheres".

Antiquarian Horological Society (at the Science Museum, Exhibition Road, South Kensington, London, S.W.7), at 7 p.m.—Mr. D. K. Packard (U.S.A.) : "American Clocks 1780–1840".

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—52nd Annual General Meeting. 8 p.m.—Prof. W. St. C. Symmers : "Clinico-pathological Observations on Some Cases of Fungal Infections and other Tropical Infections met with in Britain" (Series of lantern slides).

Friday, June 19

British Institute of Radiology incorporated with the Röntgen Society (in the Reid-Knox Hall, 32 Welbeck Street, London, W.1), at 11.30 a.m. and 2 p.m.—Radiobiology Meeting.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned :

Assistant Lecturer in Pure or Applied Mathematics—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8 (June 18).

Assistant Lecturer in Physics—The Registrar, The University, Manchester (June 20).

Assistant Lecturer in the Department of Chemistry and Biochemistry—The Dean, St. Thomas's Hospital Medical School, London, S.E.1 (June 20).

Lecturer or Assistant Lecturer (preferably with a good honours degree in physics, together with research experience in some branch f biophysics or molecular biology) in Biophysics—The Registrar, King's College (University of London), Strand, London, W.C.2 June 20).

Research Fellow in Biochemistry in the Department of Organic Chemistry, for work concerned with enzymic processes related to bacterial cell walls—The Registrar, King's College (University of Durham), Newcastle-upon-Tyne (June 20).

Head (man or woman with medical qualifications and an interest in education) of the Department of Health Education—The Clerk to the Governing Body, Battersea College of Technology, Battersea Park Road, London, S.W.11 (June 24).

Lecturer (Grade II) in Psychology—The Registrar, The University, Bristol (June 24).

Lecturer in Physics—The Secretary and Registrar, University College of North Wales, Bangor, North Wales (June 25).

Lecturer in Sociology—The Registrar, The University, Leicester June 27).

Assistant in Geology, with curatorial duties in the Hunterian Museum—The Secretary of University Court, The University, Glasgow June 30).

Lecturer in the History of Science—The Registrar, The University, Leicester (June 30).

Head of the Plant Genetics Section—The Academic Secretary, Weizmann Institute of Science, Rehovoth, Israel (July 1).

Research Students (with the degree of Bachelor or Master of a British university other than Manchester) in Science—The Registrar, The University, Manchester 13 (July 1).

Lecturer (qualified in chemistry, with teaching experience) in Education—The Registrar, The University, Sheffield (July 4).

Vice-Principal (graduate of a British university (any field), ubstantial teaching experience and some administrative and/or industrial experience)—The Principal, Reading Technical College, King's Road, Reading (July 6).

Reader in Indian Philosophy at the School of Oriental and African Studies—The Academic Registrar, University of London, Senate House, London, W.C.1 (July 8).

Senior Lecturer or Lecturer in Mathematics, and a Senior Lecturer or Lecturer in Chemistry (preferably Inorganic Chemistry) at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (July 10).

Lecturers or Assistant Lecturers in Zoology at the University of Malaya (Singapore Division)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (July 15).

Lecturer/Senior Lecturer in Biochemistry at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, July 18).

Senior Lecturer/Lecturer (with good general experience in the teaching of zoology and preferably a special interest in vertebrate zoology) in Zoology at the University of New England, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, July 22).

Lecturer (preferably with a special knowledge of palæontology) in Geology at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, July 31).

Lecturer (with a higher degree with botany as the major subject) in Botany at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, July 31).

Lecturer in Mathematics at Canberra University College, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 1).

Senior Lecturer in Petrology and Mineralogy at Canberra University College, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 1).

Senior Lecturer in Physics at Canberra University College, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 1).

Chairs (2) in Physics in the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 3).

Chair of Zoology in the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, August 31).

Lecturer in Psychology at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 31).

Agricultural Officer (Teaching) (with a university degree in agriculture with farming experience and a diploma in education and/or teaching experience) in Uganda to teach general tropical agriculture to students taking a three-year course approximating to N.D.A. standard—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/9/028.

Assistant Lecturer, Grade B (graduate, preferably with teaching or industrial experience) in Physics—The Principal, Medway College of Technology, Horsted, Maidstone Road, Chatham, Kent.

Junior Technical Officer or Technical Officer (preferably aged 24–30, with H.N.C. in electronic engineering or equivalent qualifications, and preferably with experience of the electronic and development departments of the electronic instrument industry), to work on the design and development of electronic apparatus and instruments for use in medical research—Dr. F. D. Stott, Churchill Hospital, Headington, Oxford.

Lecturer, Grade B (graduate of a British university) in Spectroscopy—The Clerk to the Governing Body, Battersea College of Technology, London, S.W.11.

Lecturer (preferably with qualifications in zoology and teaching and/or research experience) in Biology in the Training Department—The Warden, Goldsmiths' College (University of London), New Cross, London, S.E.14.

Lecturer (with an honours degree in physics and preferably some industrial experience) in Physics, to work mainly with National Certificate courses in Applied Physics and Engineering courses—The Principal, Cambridgeshire Technical College and School of Art, Collier Road, Cambridge.

Master to teach Physics—The Headmaster, Trinity School of John Whitgift, North End, Croydon.

Organic Chemist (with a good honours degree in chemistry and postgraduate experience), to take charge of a small team concerned with the development and manufacture of compounds labelled with radioactive isotopes, in particular sulphur-35—The Personnel Officer, The Radiochemical Centre, U.K.A.E.A., Amersham, Bucks.

Senior Laboratory Assistant (preferably with experience in chemistry), to supervise the running of the new, well-equipped science laboratories—The Senior Science Master, Uppingham School, Uppingham, Rutland.

Senior Technician (preferably with experience in biochemical or physiological techniques in man and animals), to take charge of the Medical Unit Laboratories under the Professor of Medicine—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2.

High performance at Low wavelengths

The absorption spectrum of maleic acid reproduced here emphasises the excellent performance of the SP.500 spectrophotometer at low wavelengths. The second graph shows the Beer-Lambert relationship at 210mμ, and illustrates the virtual freedom from stray light at this wavelength.

With the new fused silica prism, the SP.500 Spectrophotometer reaches still further into the ultraviolet—down to 186mμ, the limit set by the absorption bands of atmospheric oxygen. The advantages of this are two-fold: a new region, hitherto accessible only to specially prepared instruments is made available for every user, and the performance of the instrument, over the whole of the important 200mμ—240mμ region, reaches a new high level. The standard test specification for the SP.500 now stipulates not more than 0.2% stray light at 200mμ—a clear indication of the instrument's quality.

THE COUNCIL FOR SCIENTIFIC AND INDUSTRIAL RESEARCH

THE annual report of the Council for Scientific and Industrial Research for 1958* follows the pattern of the Council's first annual report last year. Shorn of the detail of the work of the various research boards and stations, it continues the review of the Department's activities commenced in 1957; but, as Lord Hailsham notes in his introduction, it is mainly concerned to indicate the broad features of the plans of the Department for the five years 1959–64. These involve a 70 per cent increase in the expenditure of the Department, from £36 million in 1954–59 to £61 million in 1959–64, rising fairly uniformly from about £9 million in 1958–59 to £14 million in 1963–64, and envisaging a 30 per cent increase in staff (at present 4,860).

The proposed expansion covers all the main fields of the work of the Department, including the activities of its research stations, increased grants for research and postgraduate training in the universities and elsewhere and allowance for increased grants to the industrial research associations, as well as greater efforts to secure the proper communication to industry of the relevant scientific knowledge available. In regard to industrial research, the Council believes that valuable ideas exist in some of the smaller industrial concerns of Britain which they themselves cannot afford to investigate, and that at the other end of the industrial scale there may be research and development projects so big that even large organizations cannot adequately finance them. As to how many of these would be appropriate subjects for Government backing the Council is non-committal; but the Department is ready to consider proposals for the support of industrial research and development, whatever the scale, which are likely to lead to results of value to the nation as a whole.

Although, however, the position of the grant-aided research associations is discussed in about three pages of the report, the work of these associations is to be the subject of a separate report and the general policy towards them is more appropriately and effectively considered when that report appears, particularly since the relevant financial information is to be published in that report. A similar consideration largely applies to the section dealing with scientific and technical information, including overseas liaison, though here we are still without promise of a relevant report. It is stated that during the next five years the Council envisages an expansion of information and advisory services, to ensure that the results of the research carried out in the Department's own stations and in the research associations are more widely known and applied. Funds are being set aside for special assistance of this kind to industry, and it is intended to make every effort to combine the various media of communication, and to link the contributions of the many different bodies concerned, in an effective manner.

One of the grant-aided associations, namely, Aslib, is, of course, specifically concerned with such work, but nevertheless the Council for Scientific and Industrial Research continues to shroud such activities largely in secrecy. No information whatever as to the magnitude of expenditure in this field is disclosed in the present report, other than that in the next few years it will average three times the present figure for the new National Lending Library. While it could not be expected that a report of this general nature should enter on the details which would facilitate effective public discussion, for example, of the plans of the Department for the National Lending Library for Science and Technology, for regional information centres, or for new information techniques, such discussion is particularly important in order to enlist the co-operation and the informed criticism which are essential for the most effective use of man-power and material resources in this field. A reasonably detailed review of activities in this field is overdue and could make an important contribution to eliminating waste of effort and securing the most efficient use of the resources of the Department.

For the rest, apart from the five-year plan, the Council's report continues its review of selected research stations and sets forth the considerations at present guiding its policy in scientific grants. Of the plan itself, Lord Hailsham expresses the view that it should stimulate the growth of science in Britain as a whole and be of great potential value in assisting British industry to keep in the forefront of new ideas, materials and processes and to equip itself technically for effective competition in world markets. In the main, expansion has been planned along the general lines proved by experience, but the Council stresses the importance of not tying expansion too closely in advance to specific projects. While it considers that the present expenditure of the Department is small in relation to the importance of its work, and that, subject to the efficient use of resources, this expenditure should rise as more scientists and technologists become available, it stresses also the need for flexibility. It seeks as much flexibility as possible in allocating its increased funds and in deploying the extra man-power those funds will provide.

The emphasis placed on experimenting with new ideas and amending policy and organization as the need arises is thoroughly sound, though different opinions may well be held as to the accuracy with which research needs can be estimated two or five years ahead and as to the importance—indirect as well as direct—of stability in research policy. The rapid expansion of grants for research and postgraduate training is, of course, aimed directly at increasing the number of scientists and technologists who have pursued advanced studies, as well as at encouraging a healthy and vigorous growth of research in the universities and similar institutions. It is proposed, for example, to double the total number of the studentships awarded by the Department from about 1,900 in 1958–59 to 3,800 in 1963–64, with an even more rapid expansion in grants for special researches, to maintain a healthy balance between teaching and research in the expected growth of academic institutions and to ensure that talent for research is not cramped by the lack of equipment and ancillary staff.

---

* Department of Scientific and Industrial Research. Report of the Research Council for the year 1958. Pp. 61. (Cmnd. 739.) (London: H.M. Stationery Office, 1959.) 3*s*. 6*d*. net.

Total expenditure in this field is planned to rise overall to three or four times as much, with considerably greater increases in selected fields. Expenditure in nuclear physics will provide for the maintenance, operation and development of large particle-accelerating machines at six British universities and for one or two new ones, as well as for research designs to secure the maximum benefit from such machines in the universities, at the National Institute for Research in Nuclear Science, and at the European Organization for Nuclear Research. Moreover, the importance of the contribution which the Department of Scientific and Industrial Research is making to our scientific research effort will be enhanced by the Council's proposal to give financial support for longer terms than was customary in the past to outstanding university investigators embarking upon promising lines of research for which the universities cannot make adequate provision. The new policy contemplates grants, where appropriate, for initial terms of three to seven years, terminating with a quinquennium of the University Grants Committee but renewable for one or two quinquennia.

The initiative for setting up these research groups will usually come from the universities, and normally each will be led by an outstanding worker in his field who is on the permanent staff of the university. This new policy, moreover, is the outcome of agreements with the other grant-awarding bodies as to the general principles which should guide the policy of the Council, and the further implications are being considered with the University Grants Committee and the other research councils. It is also hoped to encourage the growth of research teams in the human sciences more comparable with those that already exist in the natural sciences and to attract research workers of high calibre to this field. The Human Sciences Committee of the Council, which in the 1957–58 session recommended new awards and contracts totalling £53,000, is making a thorough survey of research needs, so that it may concentrate resources on a limited number of important topics, each of which falls within the province of one existing research team.

Trends in scientific grants to which the Council directs attention include the maintenance of the high standard of scholarships with the growing number of research studentships and the increasing administration by the Council of awards for the interchange of British postgraduate students in science and technology, with a limited number from funds to be provided through the North Atlantic Treaty Organization. The expenditure on grants of the Research Grants Committee rose from £476,000 in the final year 1957–58 to £617,000 in 1958–59, the increase being greatest in subjects other than nuclear physics. The Council is seeking to strike a better balance of expenditure between nuclear physics and other branches of science and technology, and here again, although the number of recommended awards rose from 115 totalling £856,000 in the previous year to 147 totalling £1,037,000, the quality of the applications was well maintained. Seven specialist subcommittees covering astronomy, biology, chemistry, geology and geophysics, mathematics, physics and technology are advising the Research Grants Committee, and in 1959 the Department is likely to be called upon to administer certain international funds for grants falling within the general province of the Research Grants Committee, such as the scheme of Senior Visiting Fellowships of the Organization for European Economic Co-operation and the Advanced Study Institutes of the North Atlantic Treaty Organization.

The Council's continued survey of present and projected research at the research stations of the Department has confirmed its view that there is a large and growing field for research appropriate to these stations, and that these stations should continue to undertake three types of research of great importance to the nation but of too general an application to be financed by any one industry or group of industries. First, there is research which assists central and local authorities to supply essential services and protect the welfare of the people. Then there is research which improves the efficiency of the economy as a whole; and lastly, comes research which provides industry with basic information for carrying out the applied research necessary to solve its particular problems.

These generalizations, and what has already been indicated as to the Council's policy in regard to scientific grants and the encouragement of research at the universities and similar institutions, including the colleges of technology, show very clearly the firm place the Department now holds in the scientific effort of Great Britain, and the varied but flexible contributions which the Council seeks to make with the modest resources at its disposal. They will not, indeed, dispose of all the difficulties. It may well depend on particular and changing circumstances whether the necessary effort is best made through the Department itself or in some other way. Nothing in this report touches on the unresolved issue of whether research affecting some essential service is best organized departmentally or through a central research department such as the Department of Scientific and Industrial Research. Changing circumstances may also determine whether the Department should enter on some particular field, or whether it is better left to a particular industry or to a university, with or without assistance from the Department.

When the criticism which Sir Hugh Beaver advanced before the Institution of Chemical Engineers a year ago is discounted to the limits of prudence, it is clear that the Council of Scientific and Industrial Research is becoming better equipped to advise on the distribution of Britain's research effort, and probably to advise on some probable effects of such a decision as that recently announced to enter on a programme of space research. The Council obviously is taking flexible views of its responsibilities and is prepared to vary its decisions and policy with changing circumstances.

The Council is anxious to remove any doubt as to the purpose of the National Chemical Laboratory, which is to undertake selected basic and applied research of national importance not being conducted elsewhere and inappropriate to any other organization. The Laboratory does not exist to cover the whole field of basic research in chemistry, and its resources are now to be concentrated fairly rigorously on a limited number of objectives. In future, these will comprise, first, problems requiring research of a fundamental nature which are of importance to the advancement of scientific knowledge and the development of industrial processes but which are inappropriate to universities and other research organizations because of the special facilities, experienced staff and continuity of effort required. As examples are cited the determination of fundamental physico-chemical properties of materials required by chemical engineers in the design of full-scale plant.

A second category comprises problems the solutions of which are of considerable importance to many industries and to the national economy, such as the control of the corrosion of metals, which could offer annual savings of several hundred million pounds. The third category is concerned with chemical researches carried out for other organizations on a repayment basis; of these, the research being undertaken for the Atomic Energy Authority on the extraction of elements of importance for the production of nuclear power from low-grade ores is at present the most important. It is in accordance with this policy that the work of the National Chemical Laboratory in the high-polymer field is being confined to work on polymer membranes and to the synthesis of resins for special purposes such as the separation of metals, and that the chemical engineering work is being transferred to the new Warren Spring Laboratory at Stevenage.

The first two categories of work appear to be pre-eminently the type of research with which the research stations of the Department in general should be concerned, and the new departure in financing chemical engineering research recently announced by the Association of British Chemical Manufacturers and the British Chemical Plant Manufacturers' Association is of some interest in this connexion. This decision is the outcome of the report of a distillation panel set up by the Chemical Engineering Research and Advisory Service Committee of the former body to recommend some basic researches, and at the moment £10,000 a year is being spent by the two Associations on six research projects at four British universities. It represents a new departure in co-operation in research of which the Council of Scientific and Industrial Research must clearly take notice, and one which could well affect the activities both of the Warren Spring Laboratory and of the Mechanical Engineering Research Laboratory (since renamed the National Engineering Laboratory), where it is proposed both to expand the resources of the Laboratory over the next five years and to concentrate on fewer projects.

In such a context the decision to make a deputy director both at the National Physical Laboratory and at the National Engineering Laboratory primarily responsible for fostering close relations with industry may prove to be of particular importance. The Council has also reorganized the Electricity, Metrology and Physics Division of the National Physical Laboratory, together with the Test House, on a functional, instead of a subject, basis in those Divisions: Standards, Applied Physics, and Basic Physics. The last is responsible for pioneering developments in certain branches of modern non-nuclear physics which have potential applications in industry, and the Council believes that the programme of fundamental research in new fields now taking shape will attract a strong team of able young scientists to the Laboratory.

While the Department has now largely shed its responsibilities for research on timber and on food, it accepted on April 1, 1959, responsibility for the Tropical Products Institute. This research station will continue to seek to improve the economic viability of the undeveloped territories of the tropics, primarily those that form part of the Commonwealth, and to advance the technology of existing industries as well as the introduction of new industries by means of research into new uses for tropical plant and animal products. Such work will continue to be supported from Colonial Development and Welfare Funds, and the new arrangement should strengthen the relations already existing between the Department and the Colonial Research Council and the Colonial Products Council; but equally it indicates the need for the Council of Scientific and Industrial Research to be considering closely the location and organization of Colonial research.

This second report of the Council for Scientific and Industrial Research should remove some of the misunderstandings as to its work and responsibilities which have been freely expressed in recent years. It does not, indeed, deal with the question of the direction or distribution of the scientific and research effort of Britain at the highest level; but it does suggest that, within its own field and limits, the Council is well qualified to strengthen that effort not merely in specific or particular ways but also frequently to restore the balance, for example, between research in nuclear and in non-nuclear physics, and to provide flexibility and variation. The sixty pages of the report contain ample material for informed discussion of many aspects of Britain's effort in scientific and technical research.

SCIENCE AND SOCIETY

Our Debt to the Future

Symposium presented on the Seventy-fifth Anniversary, 1957. Edited by E. G. D. Murray. (Royal Society of Canada "Studia Varia" Series, Vol. 2.) Pp. viii+133. (Toronto: University of Toronto Press; London: Oxford University Press, 1958. Published for the Royal Society of Canada.) 32*s.* net.

THE papers which have been collected under the title "Our Debt to the Future" cover a wide field. In these general addresses the Governor-General, Rt. Hon. V. Massey, puts some pointed questions to Fellows of the Royal Society of Canada and suggests that they might concern themselves more closely with the whole intellectual life of the community. The president, Dr. W. A. Macintosh, reviews the development and work of the Society, and Dr. D. L. Thomson discusses the roles of the scientist and the scholar in Canada's future, and there are five other groups of papers. These consider, respectively, the penalties of ignorance of man's biological dependence, the social impact of modern technology, Canada's economic potential in the light of science, human values and the evolution of society, and Canada's human resources.

In spite of this diversity the symposium displays a noteworthy unity and its presentation of the contribution which scientists and scholars can make to national development is markedly free from technicalities, and is a happy demonstration of the possibility of that venture into communication to which the Governor-General summoned the Fellows of the Society. It demonstrates what can be done to ensure that public opinion, and the legislative and diplomatic action it initiates, are adequately informed and to diminish the danger of learning and scholarship being submerged in a technological servitude. It indicates questions to which answers must be sought here as in Canada if our educational institutions are to be shaped to meet the needs of the day, and if a reasonable solution of the problems of power and responsibility, of wisdom and learning, is to be found before disaster falls on us.

Such questions are raised, with the fitting note of urgency, in the Governor-General's address. The presidential review of the past brings into sharper focus the opportunities of the future and the moral and intellectual challenge they offer with its emphasis on cultural and humanistic values as well as adequate scientific and technical knowledge and skill. That is further underlined by Dr. Thomson, who, while deprecating the distinction between the scholar and the scientist, insists that we must both stimulate the spirit of enterprise and adventure in youth, and seek to train men and women not only professionally competent but also having access to those deep wells in which lie the secrets of the future.

The contributions to the symposium dealing with the biological sciences are concerned more specifically with Canadian problems, but they begin and end with a plea that scientists should demand and be granted more influence in the use of their knowledge, more say in determining financial needs for scientific research and some control over the implication of science for political expediency. Mr. R. H. Manske frankly urges scientists to take a more active part in public affairs if only because of the public benefit to be derived from the more objective thinking in public affairs which the whole training of the scientist has been designed to encourage.

Some of the wider issues which are involved in the social impact of technology are discussed in the following symposium. Mr. V. W. Bladen points to problems calling both for research and reflexion, for example, in regard to investment, to leisure, to resistance to change, while Dr. E. W. R. Steacie directs attention to the influence which society itself has on the guiding of technological advance and points out that the development of scientific knowledge and the potential technological advances which may arise from it have given society, for the first time, a chance to make decisions on many matters previously largely or wholly beyond its control. All science can do is to increase the fund of natural knowledge and thus increase our potential control over our environment. What society does with this power is a social problem, and if there is a conflict between the scientist and the humanist to-day Dr. Steacie suggests it is not out of narrowness versus breadth but rather one of understanding Nature compared with understanding man. Mr. W. H. Watson also stresses the need to learn to combine the solid tradition of broad human understanding with an appreciation of the need for new intellectual tools adequate to deal with practical matters. The solution of actual problems is often made more difficult by technical inadequacy of the means available, and many of the men who by endowment, training and experience are entrusted with commenting on the broad human situation are often unable to comprehend the scope of the changes that are imminent. By separating themselves from science they have lost touch with a large and important part of the intellectual life of modern man. Mr. Watson does not claim that the methods of science are the only methods that men may be disposed to use, but he points out that through efficient educational processes new ideas work their way with cumulative effect to cause social change beyond our imagining.

The symposium on science and economic potential, although concerned essentially with Canada's own economic resources, brought to light a divergence between the views of the economist and the specialist in resources or conservation which is of some general interest since, as M. M. Lamontagne remarks, it increases the difficulty of developing adequate policies for the utilization and conservation of resources. That on human values and the evolution of society is of general interest. Dr. T. W. M. Cameron, observing that society, not science, creates technology, that science is part of both culture and humanism, and that the humanist must be able to distinguish between science and technology as well as to control the advances in technology, emphasizes the limited potential of constructive thinkers. We need to remember that man's internal environment is under only partial mental control and that although all potentialities can be developed only a very few individuals can be really educated to be constructive thinkers. Society must seek them out and provide them with the opportunities to develop their particular talents. Far too little attention is still being paid to the human biological sciences, those which concern man as an organism. These views were further elaborated by A. S. P. Woodhouse who, agreeing that education is the principal means of preserving and spreading if not of advancing civilization, urged that such education should in its character reflect and in its operation fortify two of the distinguishing marks of a civilized society: permanence and progress. This debate about the ends of education continued in the concluding symposium, in which J. K. W. Ferguson referred to the danger of demands for universal secondary and even higher education swamping facilities and debasing the product. Diversification of channels for post-primary education should be a practical aim and the maximum freedom of individual choice should be an ideal. Mass media had contributed much at the evocative level of education and they might possibly be used to do even more. L.-P. Dugal suggested that to restore the proper balance between liberal arts and science, thus uniting modern knowledge, was a main responsibility of our time and implied a pattern of education sufficiently flexible, especially in the early formative years, to satisfy later both the needs of the nation and the aspirations of the individuals. Finally, W. B. Lewis took up Dr. Steacie's challenge, how much efficiency did we want, and referred to the importance of finding new ways, especially by the improvement of our means of communication, of helping the universities to deal with increasing numbers without lowering standards. Further, the research institute and the university could and should be mutually helpful. We should ensure that adequate technical aids were available and that more care was taken to see that the tools were appropriate to the purpose so that man-power was used efficiently.

R. BRIGHTMAN

RECENT DEVELOPMENTS IN PLANT PHYSIOLOGY

Annual Review of Plant Physiology

Vol. 9. Edited by A. S. Crafts in association with Leonard Machlis and John G. Torrey. Pp. x+510. (Palo Alto, Calif.: Annual Reviews, Inc., 1958.) 7 dollars.

AS with previous volumes, the Annual Review of Plant Physiology for 1958 covers a wide range of topics. In this volume they extend from the physiology of salt tolerance, reviewed by L. Bernstein and H. E. Hayward, to post-harvest physiology of fruits, discussed by R. Ulrich; from the quantum yield in photosynthesis, dealt with by R. Emerson, to morphogenesis in lower plants, considered by L. F. Jaffe.

In the introduction to this volume, the editor refers to the changing emphasis with time in the field of plant physiology, and among a number of subjects on which emphasis has been laid in the past he includes auxin *a* and auxin *b*. If these have suffered eclipse, the interest in growth substances is as lively as ever, for no less than three of the fifteen reviews which make up this volume are concerned with auxins. J. A. Bentley deals with the naturally occurring auxins and inhibitors, P. M. Ray with the destruction of auxin, and A. C. Leopold with the uses of auxin in the control of flowering and fruiting. The related topic of herbicides is considered by E. K. Woodford, K. Holly and C. C. McCready. The extent of the bibliographies to these four articles, which contain respectively 231, 159, 190 and 357 references respectively, of which only a few are earlier than the year 1950, gives some indication of the current interest in growth-regulating substances.

Two reviews deal with special aspects of plant metabolism. In one of these, L. W. Mapson considers the function of ascorbic acid in plants. The universal presence of this substance in active metabolizing cells suggests that it has some essential function and, although it is not by any means clear what this is, it is useful to have this statement of the present position. Perhaps in no aspect of plant metabolism does fresh information accumulate more rapidly than in nitrogen metabolism, and in this field E. W. Yemm and B. F. Folkes write on the metabolism of amino-acids and proteins in plants, the problems of the synthesis and interconversion of amino-acids and their relation to protein metabolism being dealt with particularly thoroughly.

An article by W. Reuther, T. W. Embleton and W. W. Jones on mineral nutrition of tree crops deals chiefly with the major nutrients, nitrogen, phosphorus, potassium, calcium and magnesium, including the effects of their deficiencies or excess and their relations to quality of fruit. Some data are also given with regard to micro-nutrients and the inter-relationships of the mineral nutrient elements.

The physiology of one particular plant, tobacco, is the subject of a contribution by R. A. Steinberg and T. C. Tso, while the physiology of a whole group of plants, the freshwater algae, is reviewed by R. W. Krause in a paper with a bibliography containing 467 references. The volume concludes with contributions on the biogenesis of flavenoids by L. Bogorad, and on cytochromes in plants by L. Smith and B. Chance.

This volume is well up to the high standard of its predecessors and will be invaluable as a work of reference for plant physiologists wishing to obtain a view of recent developments in those aspects of plant physiology outside their own specialist interests.

W. STILES

MATHEMATICS FOR THE PHYSICAL SCIENCES

Ancillary Mathematics

By Prof. H. S. W. Massey and H. Kestelman. Pp. xvi+990. (London: Sir Isaac Pitman and Sons, Ltd., 1959.) 75*s*. net.

IN the post-war revision of examination syllabuses in the University of London, much attention has been given to the amount and kind of mathematics required to-day by a student whose chief interest is in one of the sciences. While a good knowledge of calculus and differential equations is still necessary, there is an increasing demand for a wider scope and a deeper logical understanding: the scientist can no longer safely rely on a manipulative technique built on sketchy foundations. The present volume is designed to meet present-day needs in physics and chemistry, and should see the student from his *A*-level mathematics as far as the end of his first year at the university. Such a course cannot but be voluminous, since it includes, for example, three-dimensional geometry as far as the elements of differential geometry, spherical trigonometry, differential and integral calculus of functions of more than one variable, the elements of the calculus of variations, as well as a concise but comprehensve treatise on particle and rigid dynamics, using vectors and moving axes, and going as far as Lagrange's equations and variational principles such as Hamilton's. Yet there is nothing superfluous in the book's 1,000 pages; one may even regret that there is no mention of matrices or tensors, and that complex-variable theory stops at the Cauchy–Riemann equations and does not touch on Cauchy's theorem.

Though one may suspect that, of the distinguished authors, the Professor of Physics is responsible for much of the motivation while the Reader in Mathematics has been the keeper of the mathematician's conscience, there is no evidence of any such dichotomy in the book itself. It is an integrated piece of work; mathematical rigour is not something to be taken or left according to taste, it is woven into the stuff and fabric of the volume. Proof is as important to the scientist as it is to the mathematician: "if scientists to-day continue to practise the errors condemned by Berkeley, it is because on most occasions they are content with rules, not proofs" (p. 76). But here and there, when a piece of needed technique depends on a difficult proof, the argument is left in small type, a warning to the reader that there is no royal road.

Every point of importance is illustrated and emphasized by worked examples, and there is a more than adequate supply of exercises for the reader, mainly taken from recent examination papers in the University of London. There can scarcely be a better text-book for the young physical scientist who has realized that Kelvin's demand for "a guid bellyful o' mathematics" is even more urgent to-day.

T. A. A. BROADBENT

ANCIENT IRELAND

Early Christian Ireland

By Máire and Liam de Paor. (Ancient Peoples and Places, Vol. 8.) Pp. 264 (76 plates). (London: Thames and Hudson, Ltd., 1958.) 25*s*. net.

THIS volume of the Ancient Peoples and Places Series lives up to the high standard of production and half-tone illustration we have come to expect from Messrs. Thames and Hudson. The book, presumably intended more as a convenient handbook for the educated layman than as a reference work for the scholar's shelf, is most pleasantly written; so much so, in fact, that one tends to be beguiled by the easy style and to slide, unthinkingly, over some errors of fact and uncertainties of interpretation.

For the layman the volume is adequate and competently handled. With a few exceptions, there is little new in it and there is general adherence to established chronological and art-historical schemes, especially those adapted to an English taste.

A more critical appraisal discloses instances of poetic writing which will be passed over by the foreign reader but which, in Ireland, may cause some questioning. For example, on p. 15, the authors tell us that "all the kings of Ireland . . . could trace their descent from Adam, naming an ancestor in each generation". This is romantic but not strictly accurate: the *fili* may have been able to do this, but not their royal overlords. Again, it is stated (p. 19) that "the highland periphery [of the island] can provide only scattered and separate refuges for older traditions". This is a statement which it is difficult to substantiate. On p. 32 we are told that ". . . it seems likely that the hill-forts of the Iron Age were passing out of use in St. Patrick's time", but we are left guessing as to what these monuments are and what evidence there is for their falling into disuse.

On p. 34 we are told that "the fifth-century missionaries brought the use of letters to Ireland" but on p. 61 the statement is made that the Ogham stones "in a rune-like cipher [it is not rune-like—J. R.] based on the Roman alphabet" are "perhaps as early as the fourth century". In fact, there is some slight evidence, which the authors might have investigated, to suggest that certain classes in Ireland were acquainted with letters at an even earlier stage.

We get general statements such as that on p. 54: ". . . in time the monastic workshops became the chief centres of craftsmanship in the country", a statement for which there is only the slightest archæological evidence, especially when one remembers the special social and legal position of the *aes dána*, the lay guild of craftworkers, and the existence of so many non-monastic *ateliers*, such as those at Lagore, Garranes, Garryduff, etc.

There are several instances of a lack of digestion on the part of the authors of the book, an indication that they have not made up their minds as to what theory they should hold on particular issues. For example, on p. 143, Byzantine and Carolingian iconography is stated to have been drawn upon by the carvers of the scripture crosses and reference is made to the Continental panelled ivories; but no suggestion is made as to the origin of the panels on the high crosses. On the other hand, on p. 154, in discussing the metalwork, it is implied that the panelling is derived from what the authors call the "Trewhiddle style of southern England". This, then, leaves one reader at least facing the question: do the authors mean that the *crosses* are Irish, the scriptural scenes on them Byzantine and Carolingian, and the framework of the panels English? If this is what they mean, it might have been conveyed more clearly, though it might not even then have received general acceptance.

It is a pity that the book contains a fair share of misstatements and errors of fact, most of which could have been checked by reference to the specimens exhibited in the National Museum of Ireland. A few random examples will suffice: (p. 35) the trumpet stated to be from "Annaclone, Co. Down" must be that from Ardbrin, Co. Down; it has no mouth-disk and bears no repoussé ornament; (p. 39) the Boyne bracelet has not an ornithomorphic whorl in red enamel. No enamel remains and there are no birds' heads on the ends of the triskele arms (p. 171). It is the front and not, as here stated, the back of the Cross of Cong which is panelled; and p. 96 contains the extraordinary statement that "crucibles for smelting copper and bronze are fairly common".

It is a pity, too, that elaborate Irish spellings were used when even the reformed Irish spelling would have been phonetically easier. For example, in a work in English, why not use the well-known form of the personal name "Mahon" rather than the ugly-looking (and for most people unpronounceable) "Mathghamhain"; and, if one insists on being traditionally Gaelic in one line, one should strive to be correctly Gaelic in the next by writing "Dál gCais" for the authors' incorrect "Dál Cais".

Finally, why use a term that is as historically meaningless (though current) as "Dark Age", and why apply it to the ninth century in Ireland?

What appear to me as faults in an otherwise excellent production have been pointed out; they are all such as can be corrected in a second edition, for I am sure that a volume that contains as much valuable information as this does, that is as well illustrated and as cheaply produced, will undoubtedly be in demand for a long time. JOSEPH RAFTERY

THE ASTRONOMICAL EPHEMERIS, 1960

By D. H. SADLER, O.B.E.
Superintendent, H.M. Nautical Almanac Office

"THE Nautical Almanac and Astronomical Ephemeris" (usually referred to by its abbreviation, "Nautical Almanac") was first published, by Nevil Maskelyne, the fifth Astronomer Royal, for the year 1767. It has since been published annually under the same title, but with variations of content reflecting the varying requirements of navigation and astronomy. Beginning with the edition for 1960, the title has been changed to "The Astronomical Ephemeris": the volume has been completely unified with the corresponding United States publication, "The American Ephemeris and Nautical Almanac", and further changes of content have been introduced.

A change of title was inevitable: the Almanac has long ceased to serve navigators and, with the introduction of Ephemeris Time, is now still further removed from the requirements of navigation. The title "The Nautical Almanac" will henceforward be used, in the United States as well as in the United Kingdom, for the unified edition of the Almanac for surface navigation previously entitled "The Abridged Nautical Almanac" ("The American Nautical Almanac" in the United States). Thus, the original title is to be regarded not as discontinued but as divided into two parts; the two publications, the astronomical and the navigational, each continue the tradition of the original in both title and content. The present change of title is, in fact, a long overdue consequence of the recognition, so long ago as 1914, that the requirements of the astronomer and navigator could not be met in a single publication.

Unification with "The American Ephemeris" (which still retains its title) follows the similar unification of the navigational almanacs, and sight reduction tables, for both air and surface navigation. It may seem strange that, in this practical form of international co-operation, astronomy should have to follow the lead set by the essentially practical science of navigation, in which national usages and prejudices, especially among the Services, might have created many difficulties. Actually, unification of the astronomical ephemerides has been a very much more elaborate and difficult undertaking than unification of the navigational publications. Without the maximum co-operation and goodwill in both Nautical Almanac Offices it is doubtful if this unification could have been achieved; and the minor imperfections, still to be put right in future editions, bear witness to the countless discussions, concessions and agreements that have been necessary at all stages.

The basis of the unification is that, with the exception of a few introductory pages, the two publications, "The Astronomical Ephemeris" and "The American Ephemeris (and Nautical Almanac)" are identical; they are printed separately in the two countries by photographic methods from reproducible material prepared partly in one country and partly in the other. The sharing of the responsibility, and of the work, in this way is inescapable. However, it does introduce difficulties, which are fortunately of a transient nature, in ensuring complete consistency between the two sections; the few inconsistencies that remain, which the majority of users will not notice, will be removed in future editions. Moreover, this method involves the combination, in the same volume, of two different printing styles and conventions; but the printed volume has proved to be less objectionable in this respect than was at one time feared.

The main object of unification is not the relatively small, but still significant, saving in time and cost of calculation, compilation, printing and proof reading; it is to try to ensure that the basic astronomical data are uniformly available to astronomers everywhere in a consistent form. Advanced proofs of the fundamental ephemerides of the Sun, Moon and planets are distributed to about a hundred organizations throughout the world, and reproducible material for the whole Ephemeris can be supplied on payment of a small charge through H.M. Stationery Office. The German "Berliner (Astronomisches) Jahrbuch", introduced for the year 1775, ceased publication in 1959; astronomers in German-speaking countries will use one or other of the editions of "The Astronomical Ephemeris", with the aid of a German translation of the introductory and explanatory matter.

The main change in the content of the Ephemeris is the adoption of Ephemeris Time, instead of the previous Universal Time (equivalent to Greenwich Mean Time), as the argument for the fundamental ephemerides of the Sun, Moon and planets. Universal Time is measured by means of the diurnal motion of the Sun, and its rate is directly proportional to the rate of revolution of the Earth on its axis; it therefore includes all the irregularities—periodic and secular—of the Earth's rotation. Ephemeris Time, on the other hand, is a measure of the Earth's motion in its orbit around the Sun, and is as nearly uniform as present knowledge permits. The motions of the Moon and planets, which are clearly independent of the irregularities in the rotation of the Earth, can only be predicted theoretically in terms of some uniform system of time measurement, and Ephemeris Time is therefore used. At present, Ephemeris Time at a particular instant is some 35 sec. greater than the corresponding Universal Time; the actual value of the difference between the two can only be obtained by the analysis of observations, mainly of the Moon, and is known only several years in arrear. An extrapolated value is sufficiently accurate to enable most of the other ephemerides to be given with argument in Universal Time.

A full explanation of this and other changes is given in the Ephemeris, and will be further amplified in the forthcoming "Explanatory Supplement" (to "The Astronomical Ephemeris" and to "The American Ephemeris") now being prepared jointly by the two Almanac Offices. Publication, originally arranged for the middle of 1959, has been delayed and will not now take place until about the middle of 1960.

The other changes are not substantial from the users' point of view, but many revisions have been made to increase the precision of the ephemerides—

including the introduction of the 'improved lunar ephemeris' and more consistent ephemerides of the five outer planets, all now given to one additional decimal ($0^{s}\cdot001$ and $0''\cdot01$), and improved data for calculating the apparent places of stars. Users will be most affected by: the considerable extension of the section on "Phenomena", in which are collected, both under individual phenomenon and in the form of a "Diary", the principal astronomical phenomena of general interest during the year; the revised form of the eclipse maps enabling approximate times of the contacts to be more easily read; and the new presentation, by diagrams, of the motions of Jupiter's four principal satellites, which replaces the old method of presentation originally given so long ago as in the edition for 1767. A very few users will miss the ephemerides of the Sun, Moon and planets at transit over the Greenwich meridian; comparison of observation with theory must in future be made with the fundamental ephemerides for 0^{h} E.T. Elements and predictions of occultations are omitted, but arrangements have been made for the publication of the predictions elsewhere; for example, in the British Astronomical Association's "Handbook" and in *Sky and Telescope*. Copies of the elements are supplied to the other national ephemerides.

Frequent changes in astronomical ephemerides are undesirable; apart from details of presentation, and a few minor corrections and 'second thoughts', it is anticipated that "The Astronomical Ephemeris" will remain essentially in its present form for many years.

THE PLACE OF SCIENCE IN UNIVERSITIES PAST AND PRESENT*

By THE RIGHT HON. LORD ADRIAN, O.M., F.R.S.

AFTER his death in 1579, Sir Thomas Gresham's Trustees built an institute in the City of London where he had lived. It was a college for advanced studies, and was opened 360 years ago. It was called Gresham College after its founder, the financial magnate of Elizabeth's reign who built the Royal Exchange. Both arts and sciences were to be taught in it, for it was laid down that there should be seven professors—of music, rhetoric, divinity, law, physic, astronomy and geometry. At that time England had nothing outside Oxford and Cambridge with such liberal aims. Scotland cared more for learning but lacked such great benefactors to support it.

One must not labour the comparison between Gresham College in seventeenth-century London and the Rockefeller Institute in twentieth-century New York. They were both the outcome of individual enterprise and the enlightened disposal of the wealth it had brought. But there is not much more to link them, for the fortunes of Gresham College are too closely linked to the history of seventeenth-century England.

We know very little about the students there but much more about their teachers, for there is a handsome volume on the lives of the Gresham professors published by John Ward in 1748. But we know something at least about the teaching which Gresham wanted the College to give. The regulations for the seven professors ordained that they should inhabit, study and teach there, and that there should be certain several solemn lectures with great care and diligence to be performed by every one of the said lecturers in their several arts and sciences. There was a further regulation drawn up in 1597 which is not without interest still, at all events to the Vice-Chancellors of Oxford and Cambridge. It runs "for that the greater part of the inhabitants within the City understand not the Latin tongue, whereby the said lectures may become solitary in a short time if they shall be read in Latin only; and yet withal it is very likely that diverse strangers of foreign countries who resort thither and understand not the English tongue will greatly desire to hear the reading of the said lectures. It is ordained that each lecture should be given in Latin from 8–9 in the morning and again in English from 2–3 in the afternoon".

So Gresham College started well, but it had both the advantages and disadvantages of being in the City of London, at the heart of affairs during the century when Church and State were in the balance and when the City was the central bastion of the Commonwealth in its fight with the King. There were meetings for the discussion of natural philosophy at Gresham College in 1645; but the business expressly precluded matters of theology and State affairs. Later it was some of those same philosophers who moved to Oxford and met in Boyle's rooms, where "they could converse in quiet with one another without being engaged in the passions and madness of that dismal age".

No doubt it was not so bad for the young men. At all events, after the Lord Protector had established his rule, some of the younger philosophers at Oxford and Cambridge were professors at Gresham College. William Petty was professor of anatomy at Oxford and became professor of music at Gresham College in 1650, and Christopher Wren was made professor of astronomy there in 1657, at the age of twenty-five. But until the Restoration, the City of London must have been an uneasy place for academic studies, and there is no evidence that the lectures were ever regarded as an organized course of instruction for students.

It was after 1660 that Gresham College had the full advantage of its position. The King and many of the Court were interested in the new learning; some of them had occupied their time with experiments when they were in exile, and some of the Oxford philosophers had come to London and were anxious to continue their meetings, and Gresham College was the obvious place for them.

Next year the three-hundredth anniversary of the foundation of the Royal Society of London for Improving Natural Knowledge will be celebrated, and we shall find that its early history is closely bound up with that of the College. Several large rooms were set aside for its meetings and its books and apparatus and curiosities. All kinds of experiments were demonstrated to the Fellows there, and all kinds of new instruments were made by Robert Hooke, the curator. It became the focus for every kind of scientific advance in the Newtonian period.

---

* Substance of an address delivered on May 21 at the Rockefeller Institute Convocation for Conferring of Degrees and Dedication of New Buildings (see also *Nature*, 183, 1629; 1959).

The College was something like one of the smaller foundations at Oxford or Cambridge, built around a court or a quadrangle with a cloister on two sides. There were no chapel and no dining-hall, as there were no resident students, but there were a large reading hall and a large west gallery for meetings. There were the lodgings for the seven professors, with an observatory for the professor of astronomy (erected in 1674 at a cost of £40 to "encourage Mr. Hooke in his curious and useful inquiries") and a laboratory for the professor of physic. In Virtue's engraving (dated 1739) there is a curious object standing in the middle of the grass plot and there were the usual stables and outhouses and a row of almshouses in front.

Gresham College might have played an even larger part in the development of science if the advantage of being in the heart of London had not been offset by the disadvantages of being in the City. The Great Plague of 1665 was one, for it made London uninhabitable for a time, but it affected the whole country. It sent Isaac Newton home from Cambridge to the manor of Woolsthorpe to invent the method of fluxions and master the laws of gravitation. But in London the Great Plague was followed by the Great Fire of 1666. Most of the City was destroyed. The College escaped ; but it became a refuge for the homeless, the Lord Mayor and the City Courts and offices, and the merchants and shopkeepers from the Royal Exchange. All that was left for the professors and the Royal Society was the astronomy lodging, and so the Society moved to Arundel House in the Strand. They went back to Gresham College in 1673 when the city had been rebuilt, but twenty years later they left it again, for the College needed extensive repairs and there were plans for rebuilding it. In fact the building remained until 1768, but in 1703 the Royal Society felt it would do better in a house of its own. Gresham College lost the immense advantage of its meetings and of the company of its Fellows, and thereafter its history takes on an eighteenth-century placidity. Its great period had been in the forty years before, when it had fully justified the hope of its founders that it would be "in truth a little University or Academies Epitome, as Rome when it flourished was Orbis Epitome". It had been in truth a great postgraduate centre for scientific advance.

The story of Gresham College is largely the story of its connexion with the Royal Society and with the Fellows of the Society who worked there. It is a story full of personal details about men who were remarkable for much more than their interest in science. It is copiously illustrated by portraits, letters and diaries, and it is about men as talented and as different as Boyle, Pepys, Newton, Hooke, Wren and King Charles II. It seems a pity to leave such distinguished company, but our present concern is with the beginnings of a new college in a new age, three hundred years later.

The Rockefeller Institute is not so large and impersonal that we cannot think of it and its staff in the same intimate terms ; but the great flood of scientific endeavour is now too vast to allow us to think of the individuals who move in it. There are still the giants whose heads stand out above the surface, but for the rest personal details and controversies and habits of life are not our affair. We have to survey the operations of an immense army and to do what we can to see that the troops are properly trained and led in the right direction.

It is, and has always been, the prerogative of the universities to train them. Since the Dark Ages they have been training the most intelligent young people in the way best calculated to make them valuable members of the society they would be in. As Europe became more peaceful and prosperous the medieval rulers needed the priests, and lawyers, and clerks and doctors to carry on the growing business of the State. So there was a great expansion of universities ; but now we have to face another great expansion of universities. Every country demands an increased supply of the men who were needed in the past, with the right training to fit them for the government, administration and trading concerns of the State, and there is the further demand for a new class, for the scientists who are needed to give us the full benefits of our new knowledge of the natural world and of our power to control its forces.

The popular demand is for the engineers and technologists, for they are thought to be the people who will bring immediate prosperity to their respective countries and may succeed in planting the flag of our advanced civilization on planets fortunate enough to be within range. For the medical sciences there is the popular demand for the new discoveries to check some present menace to our health or to prolong our lives beyond five score years.

Perhaps there is no great danger that scientists will be much influenced by demands of this kind. They have been, and will be, trained in universities by academic scientists who are aware of the need to study the foundations as well as to put up the temporary and showy buildings.

I think, however, that there is a danger that comes from the great expansion of scientific effort at the university-level, though it may not be as urgent in the United States as in countries where it is less well supported by private endowment. The danger I have in mind is that the centralized authority of the State will come to play a greater and greater part in directing the nature of university training and that it is likely to canalize the direction of advance in science ; to interfere to some extent with the processes by which we arrive at some entirely new outlook on outstanding problems.

When the philosophers met at Gresham College the world of Nature was all before them and they were just as ready to hear a discourse on the ventilation of mines as one on the elasticity of air. The majority of them were gentlemen of independent means who could please themselves ; and the practical problems, about clocks and navigation and agriculture, gave them new ideas on scientific principles as well as on useful arts. But the advance slowed up in the eighteenth century after its promising start in the seventeenth, and an important factor in slowing it must have been the lack of organized teaching in science and of the students to be trained from the outset for a scientific career.

Our universities collect the ablest students : these teach one another unofficially and they are, or should be, taught more officially by senior members of the university who are themselves engaged in research or have at least a close acquaintance with the research of their colleagues. In an atmosphere of intellectual ferment when investigations may be going on next door in a wide range of science the student has to make his own choice, and it is at this stage in his scientific career (if he is to have one) that the seeds may be sown which will germinate later in new ideas, and in these days there is so much ground to cover that only the most self-reliant student can do without the stimulus of varied and active research departments close at hand and of the contacts with the men who are at work in them.

The difficulty is that active research departments have become far more expensive. If they are beyond the means of a university, whoever has to pay for them may feel that results will come quicker if the research is concentrated in a few well-equipped institutes where it can go on uninterruptedly. The obligation to teach can be a most unwelcome interruption, and there are all kinds of minor distractions which universities impose on their staffs. The result has been that there is now a tendency to weaken the research activities of universities by removing some of the most fruitful fields of investigation to special institutes with little or no duty to teach.

The tendency is not peculiar to science: in Great Britain now there are institutes of historical, legal and economic research as well as those for medical, agricultural and physical sciences, some loosely tied to the university structure and some quite outside it. I must tread carefully on such controversial ground for I know what a valuable part such bodies are playing in this and other countries. I know that the policy of the U.S.S.R. has been to develop scientific research institutes under the Academy of Sciences, and that the size and cost of similar establishments elsewhere would be too great to contemplate on anything but a national basis. Yet I feel sure that we ought to resist too much paring down of our responsibilities for advancing knowledge within the framework of university courses. The most fruitful research team will suffer in the long run if it has no direct contact with the student body, and, quite apart from the claims of scientific research, the student's general education will suffer if it can never come near the growing points of knowledge.

It is, of course, arguable that no line of research lives for ever and that it may be better for a research team to have the immediate advantages of freedom from university duties in spite of the long-range disadvantages. Many of these can be avoided if there is good-will on both sides; but it is easy for ill-will to arise when the two sides work under such different conditions, when the full-time research man at an institute can envy the amenities of a university and a busy university lecturer can find no time to get on with his research. Regrets and envies of this kind are in fact the long-term disadvantage of the separation, for those who have the teaching of students at university-level will lose their enthusiasm if their best products are lured away to research institutes and those who work there may be disheartened if there is no audience to be interested in their discoveries.

It is no doubt inevitable that certain lines of research should be developed away from universities and class-rooms; many in the field of technology and applied science are more the concern of the State and of industry and would only absorb valuable space and administrative effort in a university setting. The important point is that universities should be able to maintain active research departments in the kind of science which deals with general principles and offers no immediate profit to society. It is important because such research will give life to the teaching and even more because special research institutes must work on special problems. An enlightened government or an enlightened director of a research institute may encourage work on fundamental long-range problems, and may sometimes provide a refuge for the occasional genius who cannot teach and wants to be left alone. But universities do not need to be specially enlightened to encourage unprofitable research. We are prepared to applaud our colleagues who spend their talents on the lesser authors of antiquity, and so academic scientists need not excuse themselves if they prefer to neglect the fashionable lines of advance. There is always a need for the kind of scientific research which is dictated by pure curiosity, for a fresh outlook will come more readily when there is no obvious target to fix its direction.

In saying that I confess that I am thinking of a friend of mine who has put new life into an important branch of science by never allowing his official duties in any position to influence the kind of work he should do in it. Most of us lack his detachment; but in a university we should have no scruples about deciding what line of research to follow, whereas away from one the line might be prescribed by authority.

Arguments like these, about the best conditions for promoting new developments in science, are bound to be coloured by personal experience. I have worked all my life in a university and should have been sorry to have moved to an institute with a more specific programme; but I have to admit that many of my colleagues have tried it and that their work and contentment have been none the worse. In the end we have to remember that one of the most compelling reasons for choosing a career in science is not that it will increase our comfort but that it leads into unknown territory. It is an adventure and a challenge to the human intellect, and part of its attraction is that we cannot tell how it will go. It is easy to predict that we shall soon know more about the molecular configuration of the viruses or the temperature of the fixed stars; but there is no knowing what will be found out. We cannot really predict what will be the growing-points twenty years hence, so we cannot predict what will be the best conditions for their growth. We have to plan; but the chief consideration in our planning should be that it is flexible enough to meet unpredictable demands.

The Rockefeller Institute has had many years as a research establishment of just the sort I have been attacking. Its success outside the university framework shows how little one can generalize and how much we should miss if we were tied to a single pattern. It has made great advances in medical science when it was not a university, when it was like Gresham College, with famous scientists to improve natural knowledge but without the full-time students to carry on the torch. Now there are students and courses and degrees, the younger generation to be allowed to see the advance going on and trained to take part in it.

In our crowded universities we might be pardoned for envying such ideal conditions, such handsome buildings, generous benefactors and enterprising direction, but we cannot feel anything but pride at the thought that our family has been enlarged by such a precocious, well-connected infant. The founders of our line, the doctors of Salerno, the lawyers of Bologna and the theologians of Paris if they were here now might compare themselves to the old woman who lived in a shoe and had so many children that she did not know what to do ; but they would all agree that this particular child cannot fail to be a credit to the family. It is a university to lead the way into the unexplored territories of science. The Rockefeller Institute, from now on, will make the best of both worlds, the world of research and of advanced teaching. We can all be glad that it has taken this step, which will ensure that its future will not be less productive than its past.

STRUCTURE OF POLIOMYELITIS VIRUS

By J. T. FINCH and DR. A. KLUG
Birkbeck College Crystallography Laboratory (University of London),
Torrington Square, London, W.C.1

IN this communication we report the first stages of an X-ray diffraction study of crystals of poliomyelitis virus[1-3] ; this work is a continuation of investigations begun by the late Dr. Rosalind Franklin, to whose memory we wish to dedicate this communication. There are two main results. First, we have determined the crystal structure and find that the packing of the virus particles is somewhat different from that suggested by the earlier workers[3]. The second, and more important, conclusion concerns the substructure of the individual virus particle. Here we have been able to determine the number and type of arrangement of protein sub-units in the particle. This result relates to some general principles of virus structure put forward by Crick and Watson[4,5] and to previous work by Caspar[6] and ourselves[7,8] on the structure of some small plant viruses. It suggests that there may be another general principle to be added to those already proposed. Furthermore, the X-ray photographs obtained in the course of the work show, for the first time in a virus investigation, a degree of crystal perfection comparable with that of the lower molecular weight crystalline proteins, and we have therefore also described the improvements in experimental technique which, we believe, made this possible.

The crystallization of the *MEF*-1 strain of Type 2 poliomyelitis virus from ultra-centrifuge pellets was first reported by Schaffer and Schwerdt[1] at Berkeley in 1955, and within a short time small crystals of Types 1 and 3 virus were also obtained by the same technique[2]. These crystallizations are indicative of the high degree of homogeneity achieved in the virus preparations. The methods of purification and the properties of the virus have recently been fully reviewed by Schaffer and Schwerdt[9,10].

Later, the crystallization of Type 1 (Mahoney strain) poliovirus directly from a highly purified suspension during a year's storage at 4° C. was reported[3]. A number of crystals were sufficiently large and well-formed for preliminary crystallographic studies to be made on them by the Berkeley workers. A batch of these crystals, ranging from 0·1 to 0·2 mm. in diameter, were kindly given by Drs. Schaffer and Schwerdt in 1957 to Dr. Franklin for investigation by X-ray crystallographic methods.

Experimental

The crystals were sent to us in phosphate-saline mother liquor (0·11 *M* sodium chloride, 0·01 *M* disodium hydrogen phosphate, *p*H *c.* 7·3) contained in a small specimen tube. They clearly had the same appearance as originally described by Steere and Schaffer[3], but many were rather ill-formed, so that it was not generally possible to identify all the axes of a crystal with any certainty except by X-ray photographs. The larger crystals showed weak birefringence when viewed in a polarizing microscope ; the crystals cannot therefore belong to the cubic system. The crystal morphology and its relation to the unit cell will be discussed elsewhere[11].

The crystals are very fragile and tend to stick to the walls of the specimen tube, but by gentle nudging with the tip of a capillary tube it is possible to prise them loose without much mechanical damage and draw them into the capillary with a drop of mother liquor. The first attempts to mount them in this way in glass capillary tubes were made by Dr. Franklin. They proved unsuccessful, the crystals disappearing rapidly after being introduced into the tubes. Dr. Franklin attributed this to the alkaline reaction of the glass and accordingly tried acid-treated tubes. The crystals seemed a little less unstable but still did not last long enough for an X-ray photograph to be taken.

In view of this experience, when the problem was taken up by us after Dr. Franklin's death last year, it was decided to try some neutral material for mounting the crystals. We have found quartz to be suitable. Thin-walled capillaries of fused quartz are available commercially, and we have found that the crystals will last in these tubes (sealed with wax) without any apparent deterioration for periods of at least two months.

This difference in stability of the crystals when in contact with glass and with quartz does seem to show that glass is alkaline enough to affect the stability of a crystal in the small drop of mother liquor in which it is mounted. We doubt very much that this phenomenon is peculiar to poliomyelitis virus ; the reason why this difficulty does not seem to have been encountered in other investigations of virus crystals is presumably that these were grown, in most cases, from fairly strong salt solutions. On the other hand, the poliovirus crystals were grown in dilute salt solution, and our experience suggests that quartz might be generally useful in mounting other protein or virus crystals which tend to be unstable.

The second improvement in technique which we believe enabled us to obtain good X-ray photographs stemmed from the observation of Steere and Schaffer[3] that the crystals tended to lose their sharpness after an hour or more at room temperature. The crystals have therefore always been kept cold. They were stored and mounted in a cold room at 5° C., and, during the X-ray exposure, a jet of dry air, cooled

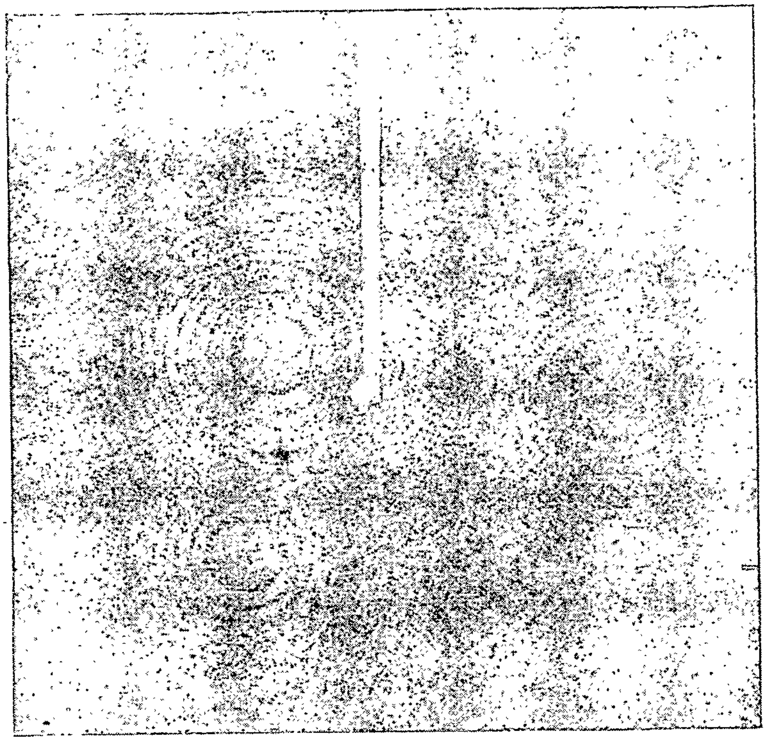

Fig. 1. X-ray diffraction photograph ('still') of a crystal of poliomyelitis virus taken with the X-ray beam approximately parallel to the [110] direction. The perfection of the crystal is shown by the presence of reflexions down to spacings of 2 A.

to about 5° C., was directed on to the crystal in the capillary tube.

There are, however, a number of difficulties attendant on this simple procedure. It is almost impossible to maintain the crystal at exactly the same temperature as its surroundings in the capillary tube. If the crystal is not in the coldest part of the tube, the water in it distils out and the crystal dries and tends to shatter. This will happen even when the crystal lies directly in the direction of the jet but is on the lee side from it. It is therefore essential, if the temperature cannot be maintained strictly uniform throughout the capillary tube for long periods of time, that the crystal be made colder than its surroundings. In this case, however, water from any traces of mother liquor present in other parts of the tube will collect around the crystal and dissolve it. This can be avoided during mounting by expelling the bulk of any excess mother liquor in the tube and mopping up all but a thin film round the crystal with thin strips of filter paper. With these precautions it was possible to keep crystals cold during X-ray exposures of 20 hours or more.

The X-ray photographs were taken with copper radiation from a rotating-anode tube at the Royal Institution, London. Each crystal will only survive a limited number of hours of exposure to X-rays, and can thus, in general, be used for one photograph only. At the beginning of the investigation, therefore, we proceeded by way of 'still' photographs[12], for which the crystal is held stationary. These give the greatest relative amount of information on a single exposure, and enable the axes of the crystallographic unit cell to be picked out on poorly developed crystals with the minimum exposure to radiation. The 'stills' we have obtained from the poliovirus crystals quite generally show crystal reflexions down to spacings of about 2 A. (Fig. 1), indicating a remarkably greater degree of crystal perfection than has been hitherto reported for any other virus crystal. The reasons for this are probably three-fold: first, the original virus preparation was very highly purified[2]; second, the crystals were not only grown in the cold[3] but also never allowed to warm up above 5° C. except possibly for very short times during transfer to the X-ray camera; third, the crystals were not brought into contact with any foreign surface except the inactive quartz. In the early stages of the investigation, a rather high proportion of the photographs showed severe crystal disorder. This we now attribute to mechanical damage, which can be minimized by careful handling.

From measurements on the 'still' photographs, the approximate crystal lattice and cell dimensions were deduced. Thereafter, precession photographs were taken with the X-ray beam parallel to the more important crystallographic directions to determine the crystal symmetry and space group. One of these photographs is reproduced in Fig. 2.

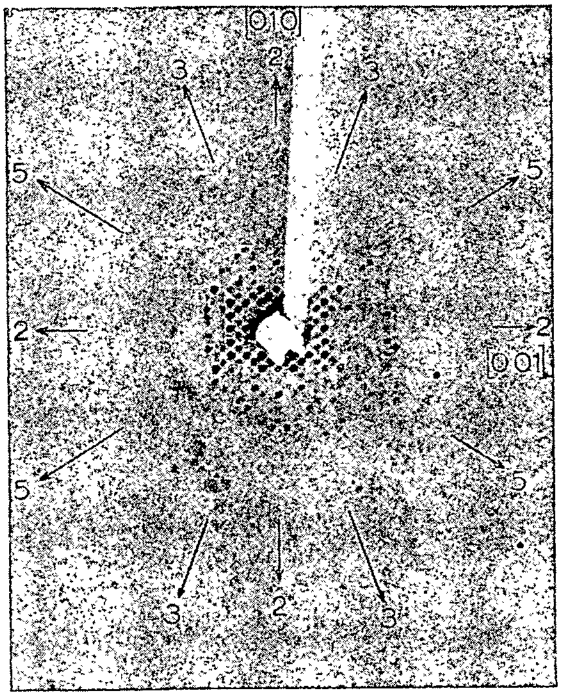

Fig. 2. Precession photograph of a poliomyelitis virus crystal taken with the X-ray beam approximately parallel to the *a* axis. The beam has been set slightly off the axis to show more of reciprocal space within the limits of the precession angle (1½°). The orientations of the 5-, 3- and 2-fold axes of the icosahedral point group 532 which lie in the basal reciprocal lattice plane are indicated by arrows. The intensities of the crystal reflexions tend to be strongest in these directions

Crystal Structure

The axes of the unit cell are at right angles to one another and their lengths (accurate to 1 per cent) are $a = 353$ A., $b = 378$ A., $c = 320$ A. The crystal symmetry is orthorhombic out to the limits of the precession photographs taken so far (0·12 A.$^{-1}$). We cannot rule out the possibility that more data would show small departures from this and that the true crystal symmetry is monoclinic or even triclinic. The discussion that follows must therefore only be regarded as applying to a resolution of 8 A.

At low angles of scattering (down to spacings of about 20 A.) reflexions with $h + k + l = odd$ are absent or very weak, indicating a pseudo body-centring. Since there is not room for more than two virus particles of diameter about 300 A. in the unit cell, the pseudo-space group is $I222$, with two virus particles in the cell, one at the corners and one at or near the centre in the same or nearly the same orientation. There is also the further implication that each particle has three two-fold rotation axes parallel to the crystals axes, that is, it has at least the symmetry of the point-group 222, and hence a minimum of four sub-units.

The general occurrence of hkl reflexions at higher angles, however, means that there is a departure from a true body-centred lattice involving either a slight displacement or rotation of the virus particles. The only possible primitive orthorhombic space-group which permits an approximate body-centred arrangement of this kind is of the type $P2_12_12$. Here the virus particle is required to have at least one two-fold axis which lies along the dyad of the space group. However, we have not been able to determine whether the latter direction is parallel to the a, b or c axis of the unit cell, since none of the $h00$, $0k0$ or $00l$ reflexions observed is of odd index. Furthermore, from the fact that there are also no systematic absences in the $0kl$, $h0l$ or $hk0$ reflexions at high angles, it is possible to show that the departure from true body-centring probably involves a combination of both displacement and rotation. Rough calculations show that a rotation of the particles through a few degrees about the crystal dyad and a displacement of only 10 A. in a direction parallel to the dyad would be enough to produce the observed departures from body-centring. We have not, as yet, been able to specify the crystal structure more closely.

The packing of the virus particles in the crystal is illustrated in Fig. 3. The balls representing the two virus particles in the unit cell have been painted differently to indicate that those of one colour do not lie exactly at the body-centres of the lattice formed by those of the other colour. If the small deviations concerned are ignored, each virus particle is surrounded by 8 others at a centre-to-centre distance of 304 A. This distance is, as one would expect, a little larger than the value of the diameter (273 A.) obtained from electron micrographs of the frozen-dried particle[13] and of replicas of frozen crystalline arrays[3]. In the (110) and (1$\bar{1}$0) planes of the crystal the virus particles pack very nearly in a regular hexagonal array (see Fig. 3), but successive layers are not close-packed together, being displaced over each other so that each particle lies almost symmetrically over a pair in the layer below. Since the sides of the unit cell are not very different from their mean value of 350 A., the crystal lattice may be thought of as pseudo-cubic. Indeed, the departures from a body-centred cubic arrangement are relatively so small as to make one wonder why the crystal symmetry is not strictly cubic, in view of the fact, discussed below, that the virus particle itself possesses cubic point-group symmetry. We hope to return to this problem at a later date.

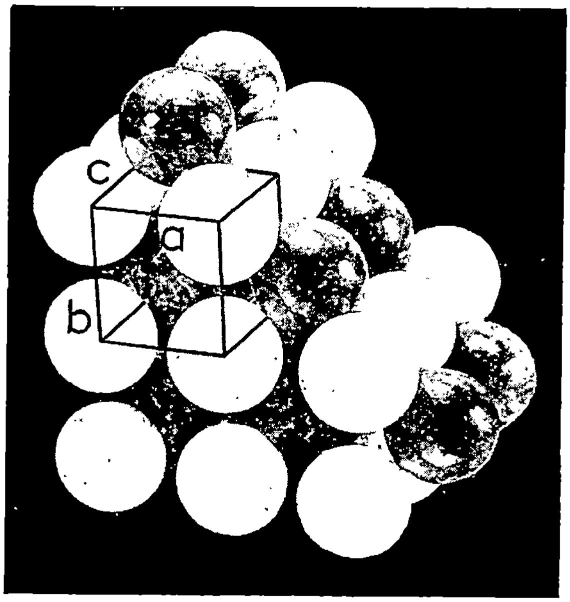

Fig. 3. Model of the crystal structure. The unit cell is orthorhombic with edge-lengths $a = 353$ A., $b = 378$ A., $c = 320$ A. The virus particles are represented by ping-pong balls. The particles fall into two crystallographically distinct sets (see text), indicated in the model by different colours. The sloping face in the model is the (110) plane in which the particles are very nearly close-packed. It is faces of this form that are most strongly developed in the crystals

The structure we have deduced from the X-ray photographs is thus different from the face-centred cubic arrangement proposed by Steere and Schaffer[3]. Their conclusion was, however, based on two sets of measurements on crystals that had undergone some special treatment. First, interfacial angles were measured on crystals that had been previously embedded in clear cement. A distortion of the crystal structure is quite likely in these circumstances. (The crystals sent to us were too small for external crystallographic measurements. It is, however, possible to relate the form development of the wet crystals to the internal structure. This will be discussed elsewhere[11].) Their second set of observations was made with the electron microscope on replicas of crystals that had been previously frozen very rapidly. The beautiful electron micrographs obtained show quite clearly a face-centred-cubic packing of the particles. There is, however, no compelling reason for believing that the structure of the wet crystals is necessarily preserved during the freezing, no matter how rapid. Indeed, one might well expect the contrary to happen, even though the virus particles themselves may not suffer any appreciable damage by the technique. At this point we might remark that electron microscopy has not, in general, given results on the crystal structure of viruses that agree with those deduced from X-ray measurements on the wet crystals. There are at least two other instances, besides that of poliovirus, where the wet crystal structure has been established as body-centred cubic[6,8]; electron micrographs[14,15], however, invariably show close-packed structures. We see no paradox in this. Only a relatively small

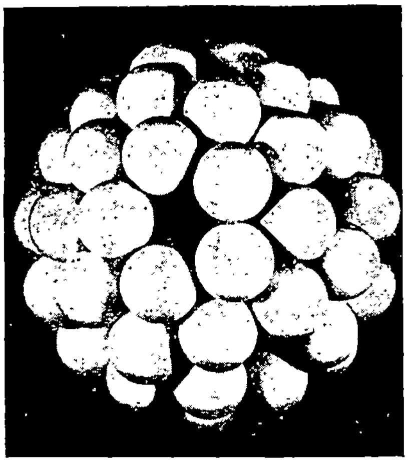

Fig. 4. Schematic model of a likely arrangement of the sixty identical structural sub-units forming the protein 'shell' of the poliovirus particle (cf. ref. 8). The actual appearance of the virus particle will depend on the precise arrangement adopted and on the shape of the sub-unit, which are not known. The diameter of a sub-unit is about 60–65 A.

shear and shrinkage is required to convert a body-centred cubic structure to a close-packed one, and it seems quite reasonable that, under the special treatment of the specimens necessary for electron microscopy (drying, freezing, etc.), the particles should re-arrange themselves to reach the close-packed structure, as the wet structure (held together by relatively weak forces) collapses or is distorted.

Structure of the Virus Particle

Some years ago, Crick and Watson[4] suggested that all small viruses are built up on a framework of protein sub-units packed together in a regular manner. This hypothesis provides a simple explanation of the regular shape of small virus particles, and was based largely on the example of the rod-shaped tobacco mosaic virus. For the 'spherical' viruses, Crick and Watson showed that there were only a limited number of ways in which a round particle could be constructed out of sub-units and that these all involved cubic point-group symmetry. Three types are possible, namely, tetrahedral (23), octahedral (432) and icosahedral (532) symmetry, which respectively imply 12, 24 and 60 identical sub-units. Under the operations of the point-group the sub-units are arranged with their centres on the surface of a sphere, but the appearance of the whole will, in general, be polyhedral.

Shortly afterwards, X-ray crystallographic studies on tomato bushy stunt[6] and turnip yellow mosaic virus[7,8], two small plant viruses containing ribonucleic acid, showed that both particles were cubic in symmetry and, in particular, possessed the characteristics of icosahedral symmetry. In the case of turnip yellow mosaic virus, it was possible, for various reasons, to show that the whole virus particle did not have this symmetry, and it was suggested that the icosahedral symmetry applied only to the protein component of the virus. As a result of more recent work[16] on crystals of the nucleic acid-free top component[17], we have been able to confirm this and to show that the ribonucleic acid of the virus has a lesser symmetry (probably tetrahedral) involving a smaller number of sub-units. (This reference to sub-units in the ribonucleic acid must be interpreted only in a configurational or geometrical sense, not chemical.)

In the case of these two plant viruses it was implied directly by the crystal symmetry that the particle (point-group) symmetry must be at least tetrahedral and so have a multiple of twelve sub-units. No such deduction is possible for poliomyelitis virus; the crystal is orthorhombic and, as we have seen above, this implies only that the virus particle has at least two (or perhaps four) sub-units.

However, the distributions of intensity on the precession photographs of the poliovirus crystals show immediate evidence of a higher particle symmetry. As in the case of the two plant viruses just mentioned, there is a concentration of reflexions of high intensity ('spikes') in directions bearing the same relation to each other as the symmetry axes of the icosahedral point-group 532 (Fig. 2). These must correspond to the transform of the individual virus particle. Because the symmetry of the crystal lattice (222) is lower than that of the individual virus particles (532), the actual symmetry of the transform of a single particle tends to be obscured because it is sampled on reciprocal lattice points which do not have the same symmetry relations as the transform. The examination of five crystallographically independent precession photographs leaves one in no doubt, however, about the underlying symmetry of the transforms. The overall distribution of intensity in the zero-layers of the reciprocal lattice perpendicular to each of the crystal axes should be the same, and this is exactly what is observed in the corresponding precession photographs.

The precession photographs also show that the orientation of the particles in the crystal lattice is such that they have two-fold axes lying parallel to the crystallographic *a*, *b* and *c* axes. The two virus particles in the unit cell both have the same or very nearly the same orientation since there is only one set of spikes. In this respect the structure resembles that of the crystal of bushy stunt virus[6], rather than that of turnip yellow mosaic virus in which particles are present in two orientations at 90° to each other[8]. The crystallographic arguments given earlier require, however, that the two particles be in slightly different orientations, and as a consequence one might expect some 'blurring' or weakening of the spikes. There does not appear to be any such tendency out to the present limits of observation, namely, spacings of 8 A., but to this resolution a feature as broadly defined as a 'spike' of intensity is not likely to be sensitive to slight differences of orientation.

The possession by the virus particles of icosahedral symmetry means that it is built up out of 60 structurally equivalent asymmetric units, but the symmetry alone does not tell us what the actual arrangement of these sub-units is. Some information on this point can be obtained by measurements of the average period of a slow modulation of intensity that is clearly discernible in the precession photographs along the 'spike' directions. This corresponds roughly to the centre-to-centre distance between sub-units in the particle. We find this distance to be 60–65 A., and if the sub-units are roughly globular, this value should give their approximate diameter. If 60 protein sub-units of this size are packed together in fairly close contact, in a way consistent with icosahedral symmetry, they will form a roughly spherical shell of diameter about 300 A., close to that of the poliovirus particle. Hence, on the general grounds set forward by Crick and Watson[4] and by analogy with the established case of turnip yellow mosaic virus, we believe that the protein component of poliovirus is the seat of the icosahedral symmetry.

We still do not know the precise way in which the sub-units are arranged to form the spherical shell of the virus. The ratio of the particle size to the distance between sub-units indicates that the sub-units in the shell are packed very compactly so that each has at least four, and probably five, neighbours in contact with it. The arrangement is therefore probably very similar to that which we have suggested for turnip yellow mosaic virus[8], and which is reproduced in Fig. 4. The actual appearance of the particle will, however, also depend on the shape of the sub-unit, which is not known at present. In electron micrographs, which are of high quality but in which the resolution is still not enough to show individual sub-units, the virus particle will tend to look polyhedral, as is observed[13].

Discussion

The above evidence indicates that the poliomyelitis virus is built up out of sixty identical or structurally very similar protein sub-units. We have added the qualification that the sub-units may not be quite identical since small differences of, say, one or two amino-acids between the protein molecules in a virus cannot be detected by the X-ray method. The molecular weight of the virus has been reported as 6·7 million[9], but in the absence of diffusion measurements this figure must be regarded as only approximate. Of this, about 25–30 per cent is ribonucleic acid[9,10], so that the molecular weight of the protein part of the asymmetric unit is about 80,000. The point-group symmetry does not preclude the possibility of each structural (crystallographic) unit being further subdivided into a number of smaller chemical sub-units ; but there is as yet no chemical evidence at all on protein sub-structure in poliovirus. Our results indicate that a search for such evidence, on the lines already applied to the plant viruses[18], would be desirable.

Our results may further help to clarify the understanding of the various components observed[2] in density-gradient ultra-centrifugation of fluid from tissue cultures infected with poliomyelitis virus. It seems very likely, by analogy with the top component[17] of turnip yellow mosaic virus, that the slower sedimenting, non-infectious, nucleic-acid free fraction designated[2,10] *C* consists simply of empty protein 'shells'. This would explain why electron micrographs of fraction *C* show particles of about the same size but flatter and less sharply delineated[19] than the intact virus particles of fraction *D*. The still lighter fraction *B*, which is immunologically related to *C*, very likely consists of groups of sub-units. Likewise, it is very probable that the 'soluble antigens'[20] that have been observed in extracts from infected cells are related to the protein sub-units used in building the complete infective virus. As for the 'small infectious component' the existence of which has been claimed by some workers[21], it is difficult to see how such particles could be consistent with the model of virus structure described in this paper. There is no suggestion at all from the present work that poliomyelitis virus is made up of more than one nucleoprotein unit.

From the present X-ray evidence we can conclude nothing directly about the structure of the ribonucleic acid of the virus. There is very little on our photographs that is characteristic of its presence in relatively large quantity in the virus. Again, this is quite analogous to the case of turnip yellow mosaic virus, which also contains a relatively high proportion of nucleic acid and the resemblance of which to poliovirus in its structural organization has already been made clear. By the same analogy, we would expect the ribonucleic acid to be located within the shell formed by the protein, and this is in accord with some electron micrographs[22] showing a dense core in the virus. Further X-ray work on the structure of the virus would be greatly facilitated by the separation (or preparation) and subsequent crystallization of protein shells free of nucleic acid (fraction *C*). We would expect the wider considerations of the problem of the structure of ribonucleic acid in ribonucleoproteins, which we have discussed elsewhere[23], to apply to poliomyelitis virus as well.

General Remarks on Virus Structure

Enough has now been said to show that the structure of poliomyelitis virus is of the same kind as that of the small, 'spherical' plant viruses, and bears out the expectation of Crick and Watson[4] that this would be the case. It is probably safe to conclude that there are no structural grounds for distinguishing the smaller animal viruses from the plant viruses.

What could not, however, have been readily foreseen is that the three small viruses the structure types of which have so far been established should all turn out to use only one type of cubic symmetry, the icosahedral, in building their protein shells. This raises the question whether there is not another general principle at work here, and one to be added to those also already put forward by Crick and Watson. We hope to discuss this in more detail elsewhere[16], but the argument may be summarized as follows. The reasons why one might expect small viruses to be made up of sub-units have been clearly stated in Crick and Watson's second paper[5]. The infectivity of a virus is carried by its ribonucleic acid, and the function of the protein part is presumably to provide some form of packaging for the former. The ribonucleic acid controls the formation of the virus protein, and, on current views[24] of protein synthesis, there is a 'coding' of the sequence of amino-acids by that of the nucleotides. There will thus be a limit to the lengths of polypeptide chain produced, set by the ribonucleic acid content of the virus, and the virus protein will be constructed from a relatively large number of small protein molecules. This is where a connexion can be made with the observed icosahedral symmetry, since, of all the types of cubic symmetry, it allows the use of the greatest possible number, namely, 60, of identical structural units in building the framework. Each structural unit may contain in turn a number of chemical sub-units, although these smaller units would not be structurally equivalent since their environments would not all be identical. One might therefore expect the number of sub-units in a small spherical virus to be 60 or a multiple of 60.

The above argument for the occurrence of icosahedral symmetry in virus structures is essentially from a principle of economy. Another, but perhaps subsidiary, reason why the icosahedral might be preferred above the other two types of cubic symmetry is that it probably also gives the most efficient packing of sub-units in a virus particle. If it is required to 'enclose' a space around a point by a symmetrical arrangement of small identical units, it can be shown that the ratio of the number of sub-units to the volume enclosed is smallest if icosahedral symmetry is employed. This is very probably the principle involved in the construction of Tipula iridescent virus, which has been shown by Williams and Smith[25] to have the shape of a regular icosahedron of diameter about 1,300 A. The particle is so large that it is rather like a little crystal, in having plane faces, for example. However, the fact that these faces are related by five-fold axes, which cannot exist in a true space-filling crystal, shows that some features of a point-group structure must be involved.

A number of people have helped to make this work possible. In particular we would like to express our thanks to the following: Drs. Schaffer and Schwerdt for providing us with the virus crystals; Prof. E. T. C. Spooner and Dr. F. Fulton for providing facilities at the London School of Hygiene and Tropical Medicine for storing and handling the crystals; Sir Lawrence Bragg for his interest and for putting at our disposal a rotating-anode tube in the Davy Faraday Laboratory of the Royal Institution, and the members of that laboratory for their generous assistance. This work was supported by a research grant No. *E*-1772 from the National Institute of Allergy and Infectious Diseases, U.S. Public Health Service. We also wish to acknowledge financial assistance by the Agricultural Research Council to one of us (J. T. F.), and a grant by the Wellcome Foundation for the purchase of a precession camera.

OBITUARIES

Mr. A. G. M. Michell, F.R.S.

Rarely in the history of engineering can theory and practice have been so happily blended as in the person of Anthony George Maldon Michell, the inventor of the thrust bearing, who died in Melbourne, Australia, on February 17.

Michell was born in London on June 21, 1870, while his parents were on a visit from Australia, to which country they had emigrated seventeen years earlier. His early schooling was in Victoria, but at the age of fourteen he accompanied his brother, J. H. Michell (later professor of mathematics in the University of Melbourne, one of the most distinguished applied mathematicians of his day), to Cambridge, and attended some University lectures there after leaving school. Returning to Melbourne, he graduated in civil engineering at the University in 1895.

Michell's early experience, which was in hydraulic engineering, led in 1901 to the invention of the Smith–Michell regenerative centrifugal pump, in which much of the energy of the fluid as it leaves the rotor is used to help drive the pump, thereby increasing its efficiency. Two years later he opened his own office, specializing as a consultant, particularly on hydro-electric schemes; the installation at the Mount Lyell copper mines in Tasmania was the first scheme of this kind in Australia.

At this time the most serious difficulty in the design of water turbines lay in the bearings. No satisfactory way of designing bearings to take an axial thrust along the shaft had been discovered, and they gave continual trouble. Michell made a special study of the theory of film lubrication which Osborne Reynolds had published in 1886, and hit on the novel yet simple idea of using pivoted bearing pads which would automatically tilt and provide the tapered film of lubricant essential in Reynolds's theory. At the same time (1905) in a remarkable paper he extended the theory to the case of the tilting pad. Few major inventions have provided so complete a solution of an apparently insoluble engineering problem: certainly in none can advanced mathematics and engineering practice have been more closely linked.

The thrust bearing was of revolutionary importance not only for water turbines but also for marine propulsion. Shafts could now be designed to transmit twenty or thirty times the horse-power previously attainable, and much larger ships than hitherto became possible. But although it was soon being widely used in Australian installations, the British Admiralty could not be persuaded to adopt it until about 1913 one was accepted by the German firm of Krupp. Thereafter its use rapidly spread in Britain and elsewhere.

In 1911 Michell successfully applied the tilting-pad principle to the construction of journal bearings, and a further most important and ingenious application appeared some years later in his crankless engine, in which reciprocating motion is converted to rotary motion, and *vice versa*, by means of tilting pads against a swash plate. Like the original thrust bearing, these inventions are notable for their simplicity. The crankless engine has never been widely adopted, although it was successful in Australia in various applications.

Among Michell's other inventions were an impulse turbine, a viscometer, the Michell–Seggel floating pad bearing (jointly with his associate, A. J. Seggel) and hydraulic transmission gear. In 1904 he published in the *Philosophical Magazine* a most original paper on the optimum design of framed structures, the importance of which is only now being recognized by aircraft engineers. He was also the author of "Lubrication" and part-author of "The Mechanics of Fluids"—both standard works. He wrote as he thought, with precision, clarity and deep mathematical insight. In 1934 he was elected a Fellow of the Royal Society in the year in which he was first proposed, and in 1943 the Institution of Mechanical Engineers bestowed on him its highest honour, the award of the James Watt International Medal.

Michell never married. Always a modest, retiring man, living quietly with his brother, he was rarely before the public eye. Those who knew him intimately speak of his keen sense of humour, his love of French literature and his wide knowledge of the Australian flora and fauna, which he cultivated at his country home in Victoria. With his passing Australia has lost its most distinguished engineer.

A. J. FRANCIS

Mr. William Hanson, M.B.E.

IN the recent death, at a comparatively early age, of Mr. William Ralph Hanson, head of the London Forecasting Office, the Meteorological Office has sustained the loss of one of its most devoted servants.

Born in 1904 into a family of teachers, he too spent some years in that profession, having graduated B.Sc. in geography while at Birkbeck College; but in 1937 he entered the Scientific Civil Service as a forecaster, serving at various stations in the south of England. He received his commission in the R.A.F.V.R. shortly before the Second World War but did not go into uniform until 1941. Associated intimately with the organization of meteorological services in the North African and Italian campaigns, he quickly reached the rank of squadron leader. It was during this period that he first showed his unusual skill in negotiation and, in satisfying not only the Royal Air Force, the Navy and the Army, but also the Americans in these theatres of war, he performed outstanding services and was mentioned in dispatches.

After the War he accepted an interesting appointment in New Zealand, and while there had his early experience of the routine broadcasting of 'weather', experience which was later to be of such value at home. In 1951 he was posted to Habbaniya, returning to Britain in 1953 to take over control of the London Forecasting Office, where until his death on May 3 he filled a post requiring not only a detailed knowledge of the working of the Meteorological Office and of other Government departments, but also an appreciation of the needs of those, outside the Service, needing weather information and advice, be they in industry, commerce, law, the Press or radio. Under his immediate direction, the automatic telephone weather service for London was inaugurated, the 'weather men' of the B.B.C. Television were put on the screen and the Meteorological Office Centenary Exhibition prepared and sent around the country. Hanson was perhaps at his happiest when dealing with such publicity and was particularly successful in bridging the gap between the anonymity of the Civil Service and the extrovert activities of Fleet Street and Lime Grove, in which places he was regarded with respect and affection. Although he worked mainly in the background, from time to time he broadcast to farmers on television and on the sound programme "The Countryside".

Early promise at the piano, violin and organ indicated a possible career in the musical profession, but of latter years his main interest, apart from Freemasonry, was undoubtedly the London Forecasting Office and the developing of new ways of presenting weather to the public. He engaged in no research and published no papers, but nevertheless was always experimenting in novel forms of presentation, and he will long be remembered for his contributions in this field.

He was much devoted to his wife and four children who survive him.

N. B. MARSHALL

NEWS and VIEWS

The Queen's Birthday Honours List

THE following names of scientists and others associated with scientific work appear in the Queen's birthday honours list:

Baronet: Prof. R. Platt, professor of medicine, University of Manchester, and president, Royal College of Physicians.

K.B.E.: Sir David Brunt, emeritus professor of meteorology, University of London, for services in the organization of the International Geophysical Year; Prof. C. A. Cotton, emeritus professor of geology, Victoria University College, Wellington, New Zealand.

Knights Bachelor: Prof. D. Baird, regius professor of midwifery and gynæcology, University of Aberdeen; L. C. Gamage, chairman and managing director, General Electric Co., Ltd.; Prof. W. V. D. Hodge, Lowndean professor of astronomy and geometry, University of Cambridge; Prof. A. J. Lewis, professor of psychiatry, University of London.

C.M.G.: T. S. Leach, chief inspector of fisheries, Ministry of Agriculture, Fisheries and Food; Prof. J. P. Baxter, vice-chancellor, University of New South Wales, and chairman, Australian Atomic Energy Commission; A. J. Haddow, director, East African Virus Research Institute; J. G. M. King, director of agriculture, Uganda; T. A. M. Nash, director, West African Institute for Trypanosomiasis Research; R. J. M. Swynnerton, director of agriculture, Kenya.

C.B.E.: Prof. W. J. G. Beynon, professor of physics, University College, Aberystwyth, for services in the organization of the International Geophysical Year; W. E. China, keeper of entomology, British Museum (Natural History); Prof. S. J. Davies, dean, Royal Military College of Science; Prof. W. R. Hawthorne, professor of applied thermodynamics, University of Cambridge; Mrs. E. L. G. Hilton, director, Radiotherapeutic Dept., University College Hospital; A. C. Monkhouse, formerly deputy director, Warren Spring Laboratory, Department of Scientific and Industrial Research; E. W. S. Press, director, chemical inspectorate, Ministry of Supply; J. A. B. Smith, director, Hannah Dairy Research Institute; Prof. H. M. Steven, professor of forestry, University of Aberdeen; Major H. Sumner, formerly president, Royal College of Veterinary Surgeons; Prof. L. J. Witts, Nuffield professor of clinical medicine, University of Oxford; Miss Mary Woodall, director, Birmingham City Museum Art Gallery; Prof. N. S. Alexander, professor of physics, University College, Ibadan; C. E. Duff, chief conservator of forests, Northern Rhodesia; C. W. S. Hartley, director, West African Institute for Oil Palm Research; J. D. Pollett, director, Geological Survey, Sierra Leone.

Institution of Mining Engineers: President for 1960–61

MR. R. G. BAKER has been elected president of the Institution of Mining Engineers for the year 1960–61, and will succeed Mr. T. A. Rogers at the sixty-sixth annual general meeting of the Institution to be held in London on January 28, 1960. Mr. Baker, who is deputy chairman of the North-Eastern Division of the National Coal Board, is the second son of the late George Baker, who was a well-known steel maker in the Rotherham neighbourhood. He was educated at the Leys School, Cambridge, and obtained a degree of bachelor of engineering (mining) at the University of Sheffield. After a period as assistant manager at Brodsworth Main Colliery, he became manager at Rotherham Main Colliery in 1934. In 1936 he moved to Earl Fitzwilliam's Colliery Co., initially as assistant manager, and was later successively manager at Elsecar Main Colliery, assistant general manager, and finally general manager of the Company. On nationalization of the coal industry, Mr. Baker was appointed deputy area general manager of No. 3 (Rotherham) Area of the North-Eastern Division and later became general manager of that Area. He was next appointed acting divisional production director of the North-Eastern Division and in 1951 he became deputy chairman of the Division. He has been secretary–investigator of the Coal Dust Committee of the Yorkshire Advisory Committee on Mining Research, a member of the Informal Committee on Shotfiring which was sponsored by the Minister of Fuel and Power, and a member of the Shotfiring and its Alternatives Committee of the Institution of Mining Engineers. Mr. Baker was elected to the Council of the Midland Institute in 1942 and was president of that Institute in 1951–52. He is chairman of the Mining Advisory Committee of the Yorkshire Council for Further Education, and a member of the Mining Qualifications Board.

Cytology at Dublin: Prof. J. Brontë Gatenby

PROF. J. BRONTË GATENBY has been appointed to a new research chair in cytology in Trinity College, Dublin. Born in New Zealand, Gatenby became a lecturer at Oxford in 1916 and in 1917 a senior demy of Magdalen College. In 1920 he was appointed lecturer in cytology in the University of London, and in 1921 to the chair of zoology and comparative anatomy in Trinity College, Dublin. Early in his career Gatenby's immense energy was directed towards the solution of the many problems associated with the study of cytoplasmic bodies and organelles of various organisms. At that time there was little knowledge of extra-nuclear components and inclusions, and Gatenby not only carried out pioneer work but inspired successive generations of students to take up cytological research. Throughout the years he continued to contribute to the understanding of the structure of animal cells, and as new techniques became available in related fields he was always one of the first to adapt these to his own subject. Much of the early work has stood the test of time and forms the background necessary for the advances in cytology that have taken place in the post-war period. Gatenby has not neglected these advances, having, for example, in 1958 visited the Argonne National Laboratory, Illinois. After many years of teaching and research, he relinquishes the chair of zoology and comparative anatomy, and is honoured by appointment to a new research post.

Zoology and Comparative Anatomy at Dublin: Prof. J. N. R. Grainger

DR. J. N. R. GRAINGER, who has been appointed to succeed Prof. Brontë Gatenby in the chair of zoology and comparative anatomy in the University of Dublin, Trinity College, entered Trinity College with a Senior Exhibition and graduated in 1947 with first-class honours in natural science. He was appointed the following year as an assistant lecturer in the Department of Zoology in the University College of Hull, as it then was. While he has been at Hull, he has established and developed the teaching of parasitology in its systematic and anatomical, as well as in its physiological, aspects with great success. Parallel with this work, and in harmony with it, his interests turned progressively towards the consideration in fundamental terms of the mechanisms underlying the capacities of organisms to respond in particular ways to changes in their environment, and in particular to changes in temperature. Of recent years, he has become widely known for his original contributions in mathematical, physical, and chemical terms to the theory of the steady state and its applications to the facts of short-term adaptations in living organisms, and also for the large volume of experimental work which he has achieved in this field. His return to his own University to succeed his old teacher will ensure that the long-established reputation of the Department of Zoology and Comparative Anatomy there for fundamental and original work in physiology will be maintained and extended into new and exciting fields, and that the work of the Department will continue to be securely based on the proper traditions of morphology and systematics.

Bacteriology at Adelaide: Prof. D. Rowley

DR. DERRICK ROWLEY, head of the Department of Bacterial Physiology in the Wright–Fleming Institute of Microbiology, London, has been appointed professor of bacteriology in the University of Adelaide as from December 1, 1959. Dr. Rowley began his professional career during the Second World War as a research chemist, dealing with isolation of intermediate compounds from the 'cracking' of petroleum, and later with improvement in methods for extraction of penicillin. He joined the staff of the Wright–Fleming Institute in 1945, being promoted to his present position in 1953. In 1950, soon after qualifying in medicine, he received a Commonwealth Fund Fellowship for study in the United States. Part of that time was devoted to immunochemical work in the laboratories of M. Heidelberger at Columbia University; the remainder was at the California Institute of Technology, where he studied problems of bacterial genetics with G. W. Beadle. During 1957–58 he returned to America as visiting professor of microbiology at Stanford University. Dr. Rowley's investigations in the field of microbiology began with work on the mode of action of penicillin, with special attention to the binding of penicillin to bacterial cell walls. Later he became interested in the non-specific effects on resistance to infection caused by injections into animals of bacterial lipopolysaccharides. This has led over the past few years to an intensive study on the general problem of natural resistance to infection with particular reference to the roles of such factors as complement, properdin, phagocytosis and so-called natural antibodies.

University Research in the United States

"SCIENTIFIC Research and Development in Colleges and Universities: Expenditure and Manpower—1953–54" (pp. iii+173. Washington, D.C.: Government Printing Office, 1959. 1 dollar) is the final part of the National Science Foundation's survey of the overall research and development effort of the United States in that period. The expenditure of American colleges and universities proper is estimated at 277·7 million dollars (of which 142 million dollars were from the Federal Government), with another 74·2 million dollars at the agricultural experimental stations and 130 million dollars at Federal research centres. Of the first figure, 205·5 million dollars are budgeted separately for research and development, 20·9 million dollars represented indirect costs of such work borne by colleges and universities and 51·3 million dollars departmental research. Of the total 481·9 million dollars, 229 million dollars were devoted to basic research. Colleges and universities, including agricultural experimental stations, employed 62,251 in science faculties, and of these 31,455 were engaged in research and development, while Federal research centres employed 5,000 research personnel. Of the science faculties, 8,300 were engaged full-time in research and development and 42,700 full-time staff were engaged in teaching, research and community service, while 11,300 part-time staff were engaged primarily in teaching. The physical sciences claimed 41 per cent of the total financial provision and 33 per cent of man-power, the biological sciences (including agriculture) 48 per cent of the expenditure and 52 per cent of man-power. Of the total science faculties, 37 per cent were employed in the physical and 40 per cent in the biological sciences. In the 190 large colleges and universities, known to conduct sponsored research projects and granting most of the advanced degrees in science, the physical sciences accounted for 60 per cent of the expenditure and 40 per cent of the man-power, the corresponding figures for the biological sciences being 33 per cent and 47 per cent.

Association of Universities of the British Commonwealth

THE report of the Executive Council of the Association of Universities of the British Commonwealth for the year ended July 31, 1958 (pp. 25. London: Association of Universities of the British Commonwealth, 1959), records that in 1957–58 the Association was asked to act in connexion with 651 appointments in member universities outside the United Kingdom, compared with 408 in 1956–57, and that the office handled 4,149 inquiries regarding advertised appointments. Advisory committees were set up for 51 appointments and reports on 94 candidates were forwarded to the universities concerned. The report refers to the work of the Association, its Council, or Secretary in connexion with Commonwealth University Interchange, Marshall Scholarships, the Frank Knox Memorial Fellowship, British Memorial Fellowships established by public subscription in Victoria, Australia, and Imperial Relations Trust Fellowships, and subjects discussed at the eleven meetings during the year of the Committee of Vice-Chancellors and Principals of the Universities of the United Kingdom are indicated in an appendix.

The Ciba Foundation

THE report for 1958 of the Ciba Foundation for the Promotion of International Co-operation in Medical and Chemical Research (pp. 25. London, 1959) records that during the year 835 visitors from thirty-six countries were provided with accommodation for short periods. Twelve evening discussion meetings were held, covering bioenergetics; mammogenic and lactogenic activities of the placenta; selective toxicity; prediabetes; gateway to the cerebral circulation; leukæmia, viruses and radiation; hormonal genesis of mammary cancer; theories of antibody production; the arterial pressure pulse; aspects of climatic physiology; maintenance of hereditary defects and diseases in human populations; and chemical protectors against ionizing radiation. A new series of evening film sessions dealing with the film as a scientific teaching and research instrument was arranged. Besides a guest symposium on the definition and classification of pulmonary emphysema, several international conferences were arranged dealing with water and electrolyte mechanism in relation to age and sex; amino-acids and peptides with antimetabolic and cytotoxic properties; the recent contribution of medical biology to ethnology, with special reference to the origin of the Etruscans; the biosynthesis of terpenes and sterols; carcinogenesis: mechanisms of action; and the regulation of cell metabolism. Nine awards were made for research relevant to the problems of ageing and six British and four French candidates were awarded short-term Anglo–French exchange bursaries. Six volumes of conference proceedings were published, and besides details of the Foundation's research forums the report includes a list of publications.

Soviet Physics—Solid State

AN important new U.S.S.R. Academy of Sciences journal made its initial appearance last January, *Fizika Tverdogo Tela*. Offering results of theoretical and experimental investigations in the physics of semiconductors, dielectrics, and on applied physics associated with these problems, this periodical publishes papers on electronic processes taking place in the interior and on the surface of solids. The American Institute of Physics has added this monthly publication to the list of Russian physics periodicals now available in cover-to-cover translation. The English language version is called *Soviet Physics—Solid State*. Further information can be obtained from the American Institute of Physics, 335 East 45 Street, New York, 17.

School Natural History Societies

The contributions made by school societies to the spread of knowledge of their own areas is shown in booklets published by the Rugby School Natural History Society and the Biology Department at Stowe School. From Rugby comes a report of the activities during 1958 and, besides details of the work of various sections during the year, includes records of Cladocera which have been made by H. R. T. Price, and Syrphidae compiled by R. H. T. Tracy and J. Peirson. Stowe has produced "An Account of the Birds of Stowe", with records of the eighty-two species which now belong to the Stowe list. Articles on particular groups of birds which are found locally have either been taken from earlier issues of the school journal or have been specially prepared. Special tribute is paid to a former master, F. P. G. Aldrich-Blake, who appears not only to have inspired his boys but also the publication of this booklet in his honour.

The Manchester Museum

The first annual report for 1957–58 by Dr. D. E. Owen, the newly appointed director of the Manchester Museum (pp. 20. Manchester: The Manchester Museum, The University, 1959), reports progress in several directions. A gallery has been set apart for special temporary exhibitions, the policy to improve the display cases throughout the Museum has been accelerated and a new guide-book has been published. A bequest of Japanese material, including lacquer, ivory and bronze and collections of coleoptera and lepidoptera, has been received from the late Mr. R. W. Lloyd. A further bequest of similar importance was the Raby collection of coins. Popular lectures on Saturday afternoons attract an average audience of sixty-one, but an experimental series on Thursday evenings was not so successful. Members of the staff continue to carry out research on the collections, and an impressive list of publications is included in the report.

Work at the Royal Society Base, Halley Bay

The United Kingdom Antarctic Report to the fifth meeting of the Special Committee for the International Geophysical Year held in Moscow in 1958 (pp. 20. The Royal Society, 1958) includes a brief summary of matters from May 31, 1957, to May 31, 1958, dealing mainly with the work attempted at the Royal Society Base, Halley Bay. This included observations of meteorology (surface and upper air), geomagnetism, aurora, ionospheric measurements, and seismology. Over 1,250 upper air balloons were launched, some reaching heights of 20 km., during April and May. The heights during most of the dark season were much below expectation, but increased with the return of the sun above the horizon. There were many instrumental difficulties resulting from the harsh environment but for the most part these were overcome. Tables of provisional climatic data reveal that the highest daily maxima temperatures ranged from + 2° C. recorded in January (the only month recording a temperature above freezing-point) to − 15° C. in August. The lowest daily minima ranged from − 51° C. in July to − 15° C. in December. Snow fell on 191 days during the year. The visual and all-sky camera auroral data have been compared with those in the northern hemisphere during the period of the equinoxes in an attempt to find if any simultaneous data are available. The ionospheric data have shown that the diurnal variation of the *F* layer over Halley Bay is mainly determined by movements of ionization and not by the primary photo-ionization processes. Radio echo data obtained from auroræ have been compared with similar data from Jodrell Bank, and it is concluded that the great auroræ of the northern hemisphere are accompanied simultaneously by greatly enhanced activity of the aurora australis.

The glaciological data involved observations of the ice shelf, several hundreds of feet in thickness and partially aground, on which the station was located. The work included measurements of accumulation and ablation, and the temperature gradient within the ice, also the determination of past variations in the net accumulations. There were also frequent recordings of small seismic shocks that have been interpreted as occurring within a few degrees of Halley Bay.

Scientific Research in Central Africa

The attractively produced and illustrated ninth annual report of the Institute for Scientific Research in Central Africa covers the year 1956 (pp. 340. Bruxelles: Institut pour le Recherche Scientifiques en Afrique Centrale, 1958) and is in three parts. The administrative report includes particulars of the management and scientific committee, the financial statement and the director's report. The second part describes the opening of the Institute's main centre at Lwiro and includes the texts of addresses on the scientific work of the Institute and other research projects relating to central Africa. The third part comprises brief summaries of the work of the Institute during the year and a list of publications by the staff of the Institute or associated workers, comprising 145 titles. Abstracts of some of these are included. In his report as director, Prof. van den Berghe refers to the completion of a study of the tsetse flies of Mutara and Ruanda-Urundi, to studies of the biology of certain noxious rodents of Kivu, of the birds of the Tshibati region and their habitats and seasons of reproduction, and on the biology of the fish of Lake Tanganyika and of its coastal fauna. Observations on the forest ecology of Mabali and the borders of Lake Tumba and the collection of a herbarium continued, as well as inquiries into the migration of natives of Ruanda-Urundi into East Africa and into the agricultural economy of Ruanda-Urundi.

Oospore Germination in *Albugo candida*

Anton de Bary's well-known illustration of oospore germination in *Albugo candida* (published in 1863), in which a sessile vesicular zoosporangium is depicted, has long held its place in standard text-books. According to T. C. Vanterpool (*Can. J. Bot.*, 37, No. 2; 1959), no other investigation on this phenomenon in *A. candida* has ever been published. He has now demonstrated that if oospores, in hypertrophied inflorescences of rape (*Brassica napus* L. var. *annua* Koch), are kept in a refrigerator for 21 months, liberated from the tissue by grinding, soaked for 7–10 days in water at 10–12° C., then changed to fresh water, they will germinate. Moreover, he has shown that a second type of zoosporangium formation exists, namely, that on the rupture of the epispore, an exit tube, 1–2·5 times the diameter of the oospore, first grows out, the zoosporangial vesicle being then formed distally. The sessile type of germination, obtained under the same circumstances, was, however, the more common. Other interesting biological observations are also noted.

Trilinear Chart of Nuclides

The enormous amount of scientific data coming from laboratories of many countries is useless unless the information reaches the user as quickly as possible, and it must be in a form convenient enough to become popular with the searcher of information. In the case of the basic properties of nuclei large tables have been very useful, the most widely spread design being that due to W. H. Sullivan, which is based on a trilinear chart. In view of the continuous increase of information and the constant improvement of data already known, the sponsor of Sullivan's tables, the U.S. Atomic Energy Commission, is now offering a service to keep the collection up to date. This is done by replacing the hexagons making up the table with new ones containing the improved information. The first two sheets of replacements contain 45 and 49 hexagons, respectively, ready to be stuck over the old ones. The data reported are: isotopes, isobars, isotones, isodiapheres, beta line of stability, atomic mass, isotopic abundance, alpha and beta stability or instability, genetic relationships, production modes, disintegration modes, nuclear isomerism, radiation energy and intensity, half-life, branching ratios, per cent internal conversion, fission yield, whole element and isotopic cross-sections, spin, magnetic moment, and degree of certainty of A and Z assignment. The issue runs to 25,000 prints. Revision sheets can be obtained on a subscription basis from the Superintendent of Documents, U.S. Government Printing Office, Washington 25, D.C.

The International Academy of Management

At a recent meeting in Athens of the Executive Committee of the International Committee for Scientific Management, Mr. John Ryan, vice-chairman of the British Institute of Management, chairman of its International and Information and Research Committees, and vice-chairman of Metal Box Co., Ltd., was one of the eight new Fellows elected to the International Academy of Management. Nominees for membership were submitted from the twenty-nine countries of the International Committee and, among others elected, were Gaston Berger of France, Peter F. Drucker of the United States, Hugo de Haan of Austria, Bernhard Hellern of Norway, Theodore Limperg of Holland, E. Hans Mahler of Switzerland and Harold B. Maynard of the United States. The Academy was created by the International Committee in November 1958, for the purpose of "stimulating and honouring distinguished personalities for their contributions to the field of scientific management". One of the first activities of the Academy will be the selection of a prize paper to be read at the twelfth World Congress on Management being held in Australia during February 22–March 4, 1960.

Symposium on Geochemistry

A symposium on geochemistry organized by the Commission on Geochemistry of the International Union of Pure and Applied Chemistry will be held in Göttingen, Germany, on August 21 and 22, to be followed by two days field excursions. The topics for discussion at the Symposium are: stable nuclides in geochemistry; long-lived radionuclides in natural systems; geochemistry of the halogens; geochemical aspects of life on earth. Further information can be obtained from Prof. C. W. Correns, Sediment-Petrographisches Institut, Göttingen, Lotzestrasse 13.

Announcements

Dr. J. S. Anderson, professor of inorganic and physical chemistry in the University of Melbourne, has been appointed director of the National Chemical Laboratory, Teddington, in succession to Dr. D. D. Pratt, who is retiring.

The Dr. W. S. Bruce Memorial Prize for 1958, commemorating Dr. W. S. Bruce, the Scottish explorer and scientific investigator in polar regions, has been awarded to Dr. Hal Lister, Department of Geography, King's College, Newcastle upon Tyne, for his glaciological work with the 1957–58 Trans-antarctic Expedition. The committee of award is appointed by the Royal Physical Society of Edinburgh, the Royal Scottish Geographical Society and the Royal Society of Edinburgh.

Messrs. Pfizer, Ltd., the Kent manufacturing chemists, have awarded a university scholarship for science worth £370 per annum to Miss Penny Howard, of Abingdon, Berkshire, and one for chemistry worth £465 per annum to George Sayce, of Hampton Hill, Middlesex.

The Plant Phenolics Group is to hold an International Symposium on "Humic Acid" in the Department of Chemistry, University College, Dublin, on September 10 and 11. Further information can be obtained from the honorary secretary, Dr. T. Swain, Low Temperature Research Station, Downing Street, Cambridge.

A Conference on Ion Exchange will be held at the Mountain View Hotel, Gatlinburg, Tennessee, during September 7–11, under the sponsorship of the Oak Ridge National Laboratory. Further information can be obtained from Wm. Rieman, III, Ralph G. Wright Laboratory, Rutgers, The State University, New Brunswick, New Jersey.

The annual meeting of the Electron Microscope Society of America will be held during September 9–12 in Columbus, Ohio, at the Ohio State University, when a symposium is to be arranged on "Contribution of Electron Microscopy of Viruses and Cells to the Problem of Cancer". Further information can be obtained from the secretary of the Society, D. Maxwell Teague, Chrysler Corporation, P.O. Box 1118, Detroit 31, Michigan.

Commission I of the International Institute of Refrigeration will be holding a conference in Copenhagen during August 19–26 as part of the Tenth International Congress of Refrigeration. The following topics will be discussed: applications of low-temperature techniques in nuclear physics; mechanical properties of metals at low temperatures; thermometry; industrial problems in connexion with the liquefaction and distillation of gases; equation of state of mixtures; fluids under high pressure; transport phenomena in gases, liquids and solids; other problems of the application of very low temperatures in industry. Further information can be obtained from Prof. A. Van Itterbeek, Naamsestraat 73, Louvain, Belgium.

Erratum. In the article entitled "Reaction of some Silicates with Chelating Agents", by Dr. D. A. Sutton, M. D. Middleton and R. A. F. Body, published in *Nature* of January 10, p. 99, in Fig. 1 "Process 1" should read "Process 2" and *vice versa*.

STEREOPHONIC SOUND RECORDING, REPRODUCTION AND BROADCASTING

IT is commonly remarked, with much truth, that engineering is impatient of scientific understanding ; history can cite repeated instances of engineering enterprise plunging ahead and producing devices of great efficiency and utility, which only afterwards have been blessed by scientific theory when this has shown them to have reached near-theoretical limits. For this, the engineer needs no apology. His first concern is not analysis but synthesis ; his purpose is a social one, and he must for ever be content with compromise, drawing upon such science as may exist, using judgment and even guesswork to satisfy his customers.

This has been true of most branches of the electronics industry ; radio, radar, television and now 'hi-fi' and stereophony are triumphs not primarily of science but of technology.

Stereophonic recording, reproduction and broadcasting, the subject of a Convention held under the auspices of the Institution of Electrical Engineers on March 19 and 20, represents one of the latest catchpurses to tickle the public fancy. Such conceits spread quickly, perhaps we might unkindly say, first among those who lust after the latest gadgets ; but if this newest branch of the radio and gramophone industry is thus encouraged, there is no doubt that musical education will also benefit eventually. But the practical systems of stereophony are as yet imperfect, and there is room for ingenuity and inventiveness—and, in my opinion, more room now for science.

This was perhaps the most disappointing aspect of the Convention, that it was concerned almost entirely with techniques ; with practical problems of recording head design, with standardizing the grooves in gramophone records, with magnetic-tape machine design for easy operation and low cost, with techniques of compatibility whereby stereophonic (twin-track) signals may be used by those unfortunates who possess conventional one-loudspeaker sets—but almost nothing was heard concerning the theoretical basis of stereophony, nor of the unsolved problem of binaural hearing. For we still do not fully understand directional hearing, either psychologically or physiologically.

The opening paper, by Mr. T. Somerville, rightly emphasized the pioneer work of Blumlein, some thirty years ago. Blumlein's name is specially associated with systems of stereophony which use coincident microphones ; these are not spaced apart in the studio, but have their directional characteristics angularly spaced, such that a sound reaching them sets up two signals with different amplitudes.

It would have helped the Convention if, at this early stage, some explanation of the essential theory of stereophonic hearing had been presented—aided by simple geometric diagrams. In this way we might have avoided several confusions which arose later. For example, simple geometry readily shows how, in Blumlein-type systems, the *amplitude*-difference at the two microphones becomes converted into a *time*-difference between the two ears of a listener at the receiving end. Of course, our sense of direction does not entirely depend upon the binaural time-interval but upon other sensory clues as well—but it is very important.

Mr. F. H. Brittain, who followed with a paper comparing normal directional hearing with that provided by the twin loudspeakers of stereophony systems, valiantly tried to clear up certain misconceptions. Thus he stressed that the signal from any one microphone in the studio, fed to one loudspeaker in your living-room, reaches both your ears. The facts that you have two ears and that usually two microphones are used are not related—the microphones do not in any sense "simulate your two ears" (one later speaker had the good grace to apologize for a slide, which showed a symbolic human head wrongly placed between two spaced microphones). Again, Mr. Brittain pointed out the distinction between *inter-aural* time-intervals (maximum, about 500 microseconds in normal conditions) and *intersource*, loud-speaker, time intervals (which may be several milliseconds). It is only the latter interval which concerns the so-called 'Haas effect', an effect which is of some importance for off-axis listening in stereophony. Thus if you sit well to one side of the room, the sound from one loudspeaker may reach both your ears 4–5 milliseconds before the sounds from the other ; in such circumstances, the sounds at each ear may fail to fuse, subjectively, and the illusion of spatial distribution is shattered.

In normal life our sense of sound direction arises from several acoustic clues ; in particular, differences in inter-aural time, intensity and in minor sound structure. But such differences alone cannot give an image outside the head—they produce right/left shifts only. We need, further, the variations of these differences with head turning (aural-kinæsthetic association). The only detailed references to these basic facts were made by Mr. Brittain, who outlined the difficulties involved in producing these desired inter-aural characteristics in the sound field from two spaced loudspeakers. He stressed that, ideally, we need loudspeakers with directional lobe-patterns of a special shape and which vary with frequency ; further, it would greatly help if the time-delay of sounds emitted from each loudspeaker could be varied suitably with angle. We could well have profited by a good deal more physical and psychological background to this Convention.

The remaining papers were technical. One by Mr. G. F. Dutton and another by Messrs. A. D. Burt and D. R. Andrews were concerned with magnetic tape recording. The first outlined the commercial possibilities of 7½ in./sec. tape records and reproducers, which now can be operated by people who are not mechanically minded. Tape records can be made with wide frequency-bands, with negligible 'print-through' between layers when stored and, most important, very low 'cross-talk' between the adjacent tracks of the two channels. This latter point was much discussed, and clearly it is a troublesome aspect of technique.

Mr. Dutton also outlined the problems of reducing the cost of stereophony on tape records, which relate to the use of slower speeds, involving better head resolution, smoother tapes and narrower tracks.

Very similar points were raised by the authors of the second paper, who dealt specially with the head design and with easily handled, quick-change tape 'cartridges'.

The final paper on the first day of the Convention, presented by Mr. J. Moir, discussed cinema stereophony. It is characteristic of cinema systems that they have used 3, 4, 5 or even 6 loudspeakers, as opposed to the usual pair of domestic systems. Now with two microphones, only two-point samples of a continuous sound field in the studio are taken, so that the two spaced loudspeakers in your living-room set up a kind of diffraction pattern; this is perhaps more or less correct if you sit in the middle, but not if you sit to one side. Cinema audiences, however, occupy a wide angle, giving corresponding difficulties. One might have hoped that this greater number of spaced microphones would be used to give a more accurate simulation of the studio sound field, but Mr. Moir pointed out that studio personnel have not, in the main, understood the true problem. Most film recordings have used single-track technique, merely switching the sound image about the screen to be roughly coincident with the photographic image, by potentiometer control of the recording level from each microphone: a difficult proceeding if two actors speak simultaneously.

An evening session was devoted to broadcast stereophony. Mr. D. E. L. Shorter stressed the difficulties of 'compatibility'—conventional one-channel reception of an intended stereophony broadcast—and the technical difficulties of modulating a single carrier wave by two sources. Dr. W. S. Percival described an ingenious stereophonic system in which the two channels convey (*a*) the main acoustic content, (*b*) the acoustic direction clues, the latter requiring very low information rates indeed; he quite rightly observed that our sense of direction is most sensitive to transient sounds, and his system takes maximum notice of these.

Two papers were delivered on the second day dealing with disk recording. Mr. Dutton referred to internationally agreed standards, both of cutting and pick-up techniques. The most-favoured system, called the 45/45 system, uses orthogonally placed needles at 45° to the vertical. For best performance, minimum wear, cross-talk, etc., fully mechanical standards have now been set up. Great attention is also being paid to improvements in cutter and pick-up design, for better reproduction and easier manufacture, a topic dealt with in some detail by later speakers.

The Convention closed with a lively discussion, admirably refereed by Mr. Moir, which provided as much interest as some of the main proceedings. Perhaps the Institution of Electrical Engineers can be persuaded to present another Convention later, dealing with principles and fundamental problems rather than so much with design of apparatus. Engineers have gone a long way in this field on inadequate theory, or on none at all. This Convention showed the need now to be pressing.

COLIN CHERRY

INDUSTRIAL PHOTOGRAPHIC AND TELEVISION EXHIBITION

THE Industrial Photographic and Television Exhibition, which was held at the Royal Albert Hall during April 20–24, was sponsored and organized by the *Financial Times*. It was stated that "the object of the exhibition was to show executives the way in which photography can aid them in many stages of the industrial process or commercial activities".

Throughout the duration of the exhibition a number of lectures were given each day on the use of photography and television in the factory, the office, training and advertising.

The most obvious use of photography is its ability to record events for future reference. A photograph can store, in one instant of time, much more information than an observer could absorb—information the importance of which may not even be appreciated at the time. Such records can be examined in detail and at leisure at a later date. They can also be compared with others taken at different times, in order to find similarities and differences, as in astronomy.

In addition, photography can extend the field of human observation. If an event lasts only a fraction of a second, high-speed photography can be used to slow the action down. On the other hand, some changes are difficult to follow because they occur so slowly. By using time-lapse photography, the time-scale can be compressed and the whole cycle of action presented in a few minutes or less.

Furthermore, sensitized photographic materials are sensitive to many forms of radiation to which the eye does not respond in a useful manner, such as infra-red and ultra-violet radiation, α-, β-, γ- and X-rays and atomic particles.

X- and γ-rays are used in radiography, which is a non-destructive method of examining the internal structure of a wide range of objects, including human beings. From X-ray and electron diffraction patterns information can be obtained about the fine structure of materials, and in the electron microscope the use of an electron beam enables greater resolution to be obtained than with the optical microscope.

Special emulsions have been developed to help the nuclear physicist record the tracks of particles such as electrons, protons, mesons, etc., moving at high speeds. From these records he gains knowledge of atomic and nuclear structure.

The most striking feature of the exhibition was a large display of excellent black-and-white and coloured prints illustrating the uses to which photography could be put in industry, research, documentation and advertising.

Among these was a set of prints taken by reflected polarized light showing the growth of magnetic domains on the surface of a metal with increasing magnetic field (International Computers and Tabulators, Ltd.).

Examples of high-speed photography included a study of spray formation from high-pressure jets (Babcock and Wilcox, Ltd., and John Thornycroft, Ltd.). Another series of photographs illustrated a method of demonstrating fluid-flow by recording the paths taken by numerous small air bubbles suspended in a liquid. The apparatus was illuminated from one side by a flash bulb through a narrow slit so that a thin lamina perpendicular to the camera axis was photographed (Harold White, for the Power Gas Corporation, Ltd.). The Bowater Paper Corporation, Ltd., exhibited a print taken at 1/8000th of a second showing the fluid pulp on the wire mesh of a paper-making machine.

Other pictures showed the use of enamel for revealing the pattern of strain in metals (A. V. Roe, Ltd.), photoelastic stress patterns in gears and pawls (International Computers and Tabulators, Ltd.), the ultrasonic testing of metals (Steel Co. of Wales) and recording of cracks in concrete (Babcock and Wilcox, Ltd.). The last firm also showed photomicrographs of metal structure.

Probably the stand which was best arranged to enlighten the hypothetical executive was that of Pye, Ltd. It was divided into a series of cubicles, each one of which showed an application of closed-circuit television, such as the transmission of printed information or instrument dial readings or the examination of machinery in operation in inaccessible or inconvenient positions. Details were also given of a special camera designed to operate inside a nuclear reactor. Similar equipment was also exhibited by Marconi Wireless Telegraph Co., Ltd., for traffic observation and control.

Rank Cintel, Ltd., were demonstrating a three-channel colour-television apparatus and a video tape recorder. They also showed how television techniques could be applied to photographic printers and enlargers to adjust the contrast of a negative to improve print quality.

Decca, Ltd., showed a data-transmitting system which used a cathode-ray tube as a scanner with a photomultiplier pick-up tube.

The three photographic firms who exhibited featured document copying and reproduction. Gevaert, Ltd., showed examples of the 'Gevacopy' process which utilizes silver image transfer for producing a few copies. If a larger number are required then an offset printing plate on aluminium can be prepared. Ilford, Ltd., demonstrated a range of machines for using 'Azoflex' paper. This is a dye-coupling process which is capable of producing either as small or as large a number of copies as needed. On the Kodak stand was to be found the 'Verifax' process. This uses a layer which is hardened by light and afterwards pigmented. Any unhardened gelatine on the 'negative' can be transferred, more than once, to other sheets of paper to obtain several copies. Also shown on this stand were the 'Statfile' and 'Recordak' machines. A new model of the latter enables both sides of a sheet of printed material to be recorded side by side on a strip of film in one passage through the machine.

These firms also showed examples of radiography, colour transparencies and prints, etc., illustrating their uses in various fields. Ilford, Ltd., had a compact processing unit for 35, 45, 60 and 70 mm. film, which should be very useful to laboratories which employ oscillograph recorders, etc.

On other stands a wide variety of photographic equipment and chemicals could be seen: cameras (still and ciné), lenses, lighting units, timers, printers, enlargers, etc. John Hadland and Co. offered a complete service for high-speed photography. Many stands offered projectors for still and ciné pictures, with and without a commentary in sound for instruction, sales promotion, demonstration and advertising.

R. J. Hercock

CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY

NEW BUILDING

A NEW wing was opened at Chelsea College of Science and Technology on April 28 by Lord Adrian. The building was planned a number of years ago before the status of the College was changed and is thus relatively small and does not allow for any increase in social amenities for the College. Plans for further buildings on adjacent sites which will provide residential and social accommodation as well as a completely new Department of Chemistry are already well advanced. A new independent College of Art is also to be built opposite the present College building. In due course the School of Art, which now forms part of the College, will occupy the new building and release accommodation which will be adapted for use by the remaining departments of the College.

The present extension, which provides an additional floor area of 17,913 sq. ft., takes the form of a four-story block running roughly from east to west and facing north to Chelsea Square, with a two-story addition facing inwards to the courtyard of the College. A gap on the second floor of the old West Wing has also been closed by the building of a new zoological laboratory and a smaller staff research laboratory. The main new building provides a laboratory, lecture room, and two store-rooms for physics, six classrooms, staff and office accommodation for mathematics, a large teaching laboratory, two research laboratories, a balance room and a lecture room for chemistry, and a studio, lithography room, store and students' rest room for art. A new students' common room is also provided, but this and the new Art School accommodation is merely exchanged for equivalent space vacated for use by the Department of Botany and Zoology and the College Library. Other rooms vacated by departments occupying the new wing will also be adapted for use by the School of Pharmacy and the Departments of Geology, Physiology and Pharmacology.

In introducing Lord Adrian, the chairman of the Governing Body, Mr. John Townsend, directed attention to the fact that the College was the only college of advanced technology which did not possess an engineering department and the only one which did possess a department of physiology. Lord Adrian referred to the important and expanding fields of training and research which come within the scope of the work of the College. While the need for many more trained engineers was well recognized, there was some danger of neglect of the biological side. Chelsea was well placed, with its large School of Pharmacy and its other science departments, to help in satisfying this need. He likened the present boom period for science to the time when Gresham College was founded in the City of London and the Royal Society began its existence. At that time there was no clear distinction between science and technology and many famous men exemplified the union of the two in their own work. The distinction began to be emphasized in the nineteenth century but now it was growing out of date again; advances could come from either direction—the demand for a prettier stocking might lead to new theories of molecular structure or the new theories might lead to new fabrics. He congratulated the students of the College on having chosen a scientific career at this exciting period of expansion and emphasized the great possibilities that lay before them.

After declaring the extensions open, Lord Adrian inspected the new buildings, and the whole of the College was thrown open to visitors.

ADMISSION OF STUDENTS TO UNIVERSITIES

ONE of the most notable contributions in the report* of the vice-chancellor of the University of Birmingham for 1958 is his account of admissions procedure. Students are chosen by the faculty admission tutors in consultation with the heads of departments. The process goes on from January every year (or earlier) until September. Applications come from all over Britain, and from overseas, in numbers far exceeding the available places. Many are from candidates simultaneously applying to other universities as well, often with a preference for Oxford or Cambridge. They furnish school records, and headmasters' and headmistresses' assessments; many of them are brought to the universities for interview. More often than not the crucial information about applicants, namely, their performance in the 'A' level examinations for the General Certificate of Education, is not available until mid-August, but it is impracticable to leave all decisions until that late date. Tentatively, at least, the university must make most of its choice before then, while the candidate also wants to exercise his choice among universities. The result is that a complicated and haphazard system of provisional offers of admission has grown up, in which the universities compete for what they think are good candidates and the candidates compete for what they think are good universities. The universities often keep the candidates on tenterhooks and the candidates sometimes treat the universities in cavalier fashion.

The position has grown worse in the past three years, and threatens to grow worse still as numbers and competition increase. No smooth and tidy system seems possible so long as General Certificate examinations are held in June and university sessions begin in October; if those events were to be separated by a longer interval of time, no one can think how to occupy the boys and girls during that interval, short of imposing some kind of civilian national service. In studying the difficulty, however, the Committee of Vice-Chancellors and Principals concluded that it could at least be mitigated, and in June 1958 the Committee made a series of recommendations to the universities (other than Oxford and Cambridge) designed to smooth the path of university applicants to a considerable extent. It asked, among other things, that application forms should be simplified and made more nearly uniform; that heads of schools should be invited to use a common form for reports on candidates; that application and acceptance fees, and special entrance examinations, should be abolished; that closing dates for the receipt of normal applications by all universities should be synchronized; that provisional offers of places should state the conditions in specific terms; that candidates should be informed as promptly as possible where they stand, and be allowed reasonable time in which to accept or decline places offered to them. Birmingham has accepted these recommendations and is giving effect to them in 1959. If all universities do the same there is likely to be a substantial improvement in an inherently difficult situation.

DIRECTORY OF NATURAL HISTORY AND OTHER FIELD STUDIES

ON behalf of the Carnegie United Kingdom Trust, the British Association for the Advancement of Science has performed a useful service to many people in compiling a directory of natural history and other field societies.

The response to 4,000 individual inquiries made by Dr. Averil Lysaght showed that some eight hundred natural history societies flourish in Great Britain to-day. These he carefully listed and provided with a geographical index so that their work may be better known and co-ordination between them facilitated.

The publication of the Directory, so shortly after the formation of the Council for Nature, reflects the increased interest in natural history. As a comprehensive work of reference, it has attempted to include all professional and amateur societies in England, Scotland, Wales and Northern Ireland which are concerned in any way with field studies (a term which provides an umbrella for a multitude of subjects from interplanetary exploration to guppy-breeding), or which, while not taking part in field work themselves, are active in publishing the results of such work. Medical societies have not been included, nor have societies devoted to horticulture, agriculture and forestry, nor those concerned with plants or animals purely for sporting or commercial purposes. School societies have only been listed if they publish some record of their work or carry out some special studies; it is impressive to note how many do fulfil these qualifications.

Of the societies listed, those which claim to be specifically concerned with natural history and field studies form the majority, with archæology and local history making a close second. A considerable number—somewhere about 10 per cent—are occupied with the preservation of the countryside in the broadest sense. Astronomy and meteorology are combined in a single section; geology has a section to itself, though many geologists must be numbered among the members of the geographical societies listed in the general section. Bird-watching and ornithology prove the most popular single subject, and the Directory reflects the growth of new types of society, such as the various spelæological societies engaged in surveying and excavating cave systems in Great Britain; the underwater swimming clubs, many of which are turning from sporting and hunting activities to the study of freshwater and marine life, as well as the development over recent years of the county naturalists' trusts.

There is a strongly local flavour to a high proportion of the societies. Life membership thrives in Scotland and diminishes with decreasing latitude; after London, Yorkshire boasts the largest concentration of societies; Lincolnshire can claim the second oldest in England (ranking next to the Royal Society), which numbered among its members Newton, Addison and Pope. Glamorgan holds the monopoly in the study of lichens, while underwater swimmers are as bold in the north and midlands as in the south. The geographical index provides an easy guide to the regional distribution.

PROPERTIES OF A RECEPTOR MEMBRANE

From THE DEPARTMENT OF PHYSIOLOGY, COLUMBIA UNIVERSITY, COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK

Spatial Summation of Electric Activity in a Non-myelinated Nerve Ending

After removal of most of the non-nervous (capsular) tissue of a Pacinian corpuscle, the sense organ's remains, consisting mainly of a non-myelinated ending, continue to be as mechano-sensitive as the intact sense organ: the ending produces generator potentials in response to mechanical stimuli of the same order of magnitude as the intact corpuscle[1]. This decapsulated preparation offers the opportunity to study the properties of a non-myelinated nerve ending in isolation. The ending is accessible for micro-electrode recording, and visually selected portions of ending can be stimulated mechanically with a crystal-driven stylus. The ending is straight and long (about 600μ); two separate regions of ending can be stimulated simultaneously with two independently driven styli.

When a mechanical stimulus is applied to a portion of ending by one stylus alone, an active response (depolarization) is detected at that region. This response is confined to the region of ending which has been stimulated mechanically, but does not propagate actively along non-stimulated portions of ending. Fig. 1 illustrates an experiment in which two micro-electrodes are placed in contact with the ending. A weak mechanical stimulus is delivered to a portion of ending close to electrode E_1. This causes depolarization of a region of membrane in the vicinity of the stimulating stylus which is recorded by electrode E_1. Electrode E_2, about 500μ apart, still detects this response, but the peak amplitude and the rate of rise of the response are markedly reduced. By systematic scanning of the ending's surface with a micro-electrode, the amplitude of the response is found to decrease exponentially with the distance from the stimulated region.

From the preceding results spatial summation of electric activity of independently active membrane regions[2] emerges as a possible mechanism to account for the well-known increase in generator potential as a function of the strength of stimulus. It was, in fact, found that the depolarization of one membrane region adds up with the depolarization of another region. In the experiment illustrated in Fig. 2 the styli of two independent crystals were each applied to a

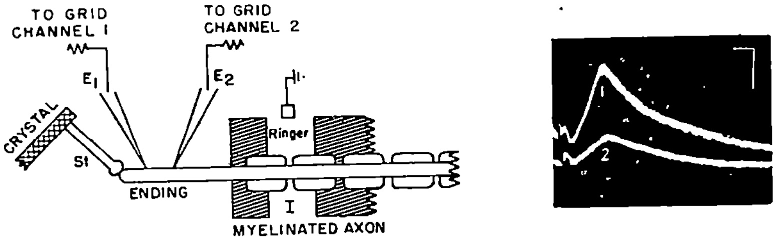

Fig. 1. Local activity confined to a small membrane portion of ending. Two micro-electrodes (E_1, E_2) connected to separate amplifier channels are placed in contact with the non-myelinated ending of a decapsulated Pacinian corpuscle. The preparation is pulled into a device which insulates the first node of Ranvier in contact with a common ground electrode from the ending. E_1 is placed at a distance of approximately 20μ, and E_2 at approximately 520μ distance from the stimulating stylus (*St*). Beams 1 and 2 give the responses to a single mechanical stimulus as recorded by electrodes E_1 and E_2, respectively. Calibration: 50 μV.; 1 msec.

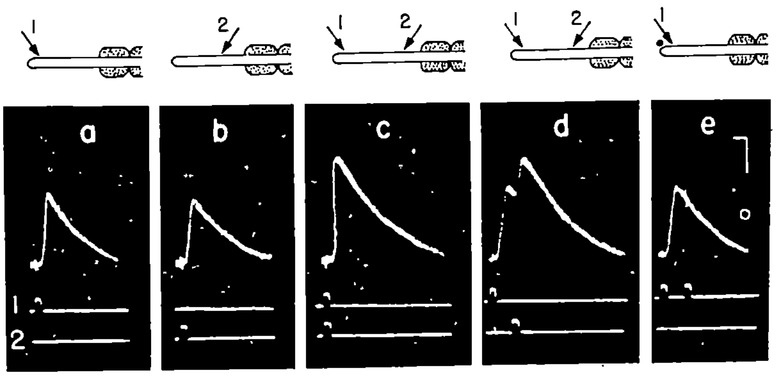

Fig. 2. Spatial summation of generator potentials in a single nerve ending. Styli 1 and 2 belong to independent stimulating crystals which deliver stimuli to two separate regions of ending. Middle and lower beams signal stimuli of styli 1 and 2, respectively. Upper beam for generator potentials as recorded at the myelinated axon. *a*, stylus 1 alone delivers one stimulus; *b*, stylus 2 alone delivers one stimulus; *c*, styli 1 and 2 deliver each one stimulus simultaneously; *d*, stylus 2 applies a stimulus 1 msec. delayed from that of stylus 1; *e*, stylus 1 alone delivers two stimuli succeeding each other at a delay of 1 msec. Calibration: 1 msec.; 50 μV.

different region of ending. The electric activity of the ending was led off by electrotonic spread from a myelinated portion of axon near to the ending with a pair of low-resistance electrodes. Such electrodes integrate current flow from the entire ending. When both styli deliver simultaneously a stimulus to their respective membrane regions, summation of electric activity is observed (Fig. 2 *c*, *d*.) The possibility of a mechanical artefact due to mechanical spread of stimuli or due to mechanical summation of stimuli is excluded by the result shown in Fig. 2*e* : if two successive stimuli, separated by the same interval as in *d*, are delivered to the *same* membrane region by one stylus alone, the second stimulus falls on the refractory trail of the preceding response[3] and fails to evoke a detectable response. This experiment in addition reveals that the refractory state (as well as excitation) is confined to that region of membrane which has been activated mechanically, but does not spread along the ending's membrane.

WERNER R. LOEWENSTEIN

Spontaneous Fluctuations in Generator Potential in a Receptor Membrane

THE receptor membrane of the non-myelinated ending of Pacinian corpuscles has the peculiarity that small regions of it can be activated independently ; as has just been shown, if a mechanical stimulus is applied to a portion of ending, the resulting active response (depolarization) is confined to that region which has been stimulated, but does not propagate actively to adjacent non-stimulated regions of the ending by local circuit excitation[2]. The generator potential of the entire ending appears to be the result of spatial summation of electric activity of functionally independent membrane regions of a certain minimal area[2]. The term 'receptor site' will be used here to designate that minimal region of membrane which can be activated independently. The term 'site' is used in its broadest sense. It does not imply structural discontinuity of the membrane ; it merely implies discontinuities in the process of activation along the ending's membrane. Evidence has recently been given indicating that a mechanical stimulus activates a statistically fluctuating population of receptor sites[4]. One of the consequences of this mode of excitation, the existence of spontaneous fluctuation in generator potential, has been explored in the experiments described under the second heading.

Isolated Pacinian corpuscles from the cat's mesentery were stimulated with mechanical pulses from a piezo-electric crystal. The pulses were monitored photoelectrically with an accuracy of 0·3 per cent. The ending's generator potential was led off with an electrode placed on the region where the non-myelinated ending joins the myelinated axon. Such an electrode records the aggregate electric activity (generator potential) of the entire receptor membrane.

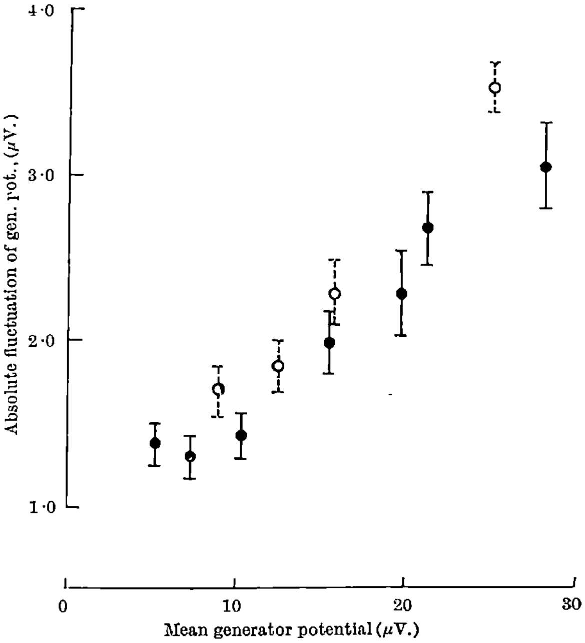

Fig. 3. Absolute fluctuation in generator potential as a function of amplitude of generator potential. Each point corresponds to the mean fluctuation (deviation) in amplitude of 50 generator potentials in response to equal mechanical stimuli ; bars subtend standard error of mean fluctuation. The mean amplitude of generator potential is varied in steps by either (*a*) varying the stimulus strength over the linear range of the stimulus strength–generator potential function ; or by (*b*) polarizing the non-myelinated nerve ending at constant stimulus strength. The mean fluctuations in generator potential obtained by procedure *a* (black circles) and by procedure *b* (open circles) are plotted against the mean amplitude of the corresponding generator potential

When equal mechanical stimuli are applied to the same portion of ending, the amplitude and rate of rise of the resulting generator potentials were found to fluctuate at random around an average value. Fig. 3 shows the fluctuations in amplitude for various amplitudes of generator potential. Each point of the curve corresponds to the mean fluctuation of 50 generator potentials produced by equal mechanical stimuli. The mean amplitude of generator potential was increased in steps by increasing the stimulus strength within the linear range of the generator potential–stimulus strength function, and the corresponding fluctuation of generator potentials (black circles) was determined for each strength. The fluctuation is seen to increase with amplitude of the generator potential. It has previously been shown that the area of activated receptor membrane, that is, the number of active sites, increases with strength of stimuli applied to the ending[2]. An increase in statistical fluctuation of active sites, and hence an increase in fluctuation of generator potential with increasing stimulus strength, such as observed in the experiment of Fig. 3, is thus to be expected. It might furthermore be expected that, as a consequence of spatial summation, the increase in number of activated sites with increasing stimulus strength be steeper than the corresponding increase in statistical fluctuations of active sites. The ratio of generator potential fluctuations to generator potential should then decrease with stimulus strength. It is apparent from Fig. 3, and further illustrated by Fig. 4, that this ratio, in fact, decreases with strength over the linear range of the generator potential–stimulus strength function. The results are thus in agreement with a system in which the generator potential is the result of spatial summation of activity of statistically fluctuating receptor sites. However, the possibility must be considered of the observed fluctuations being caused by fluctuations in mechanical stimuli. From the derivative of the stimulus strength–generator potential curve corresponding to the fluctuation curve of Fig. 3, it can be calculated that the mechanical stimuli would have to fluctuate as much as ± 4·7 per cent to account for the smallest value of observed fluctuation. However, the photoelectric control of stimuli gives us the certainty that

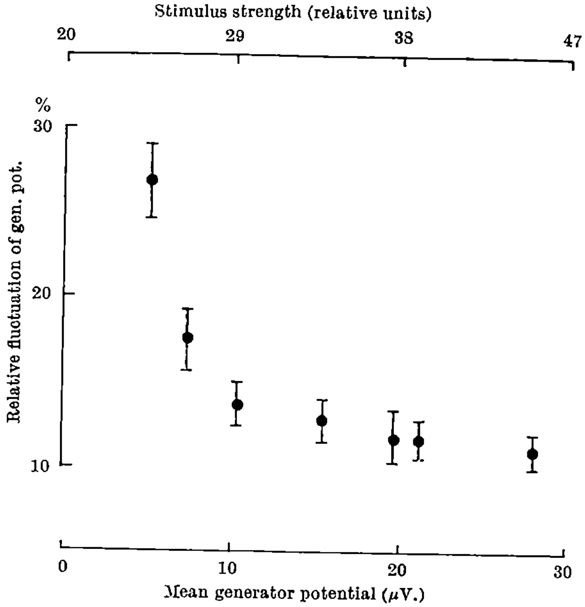

Fig. 4. Relative fluctuation of generator potential as a function of generator potential. The percentage fluctuation (100 × mean fluctuation/amplitude of generator potential) is plotted against the mean amplitude of generator potential. Data from the same ending as Fig. 3 obtained in the linear range of the generator potential–stimulus strength curve

stimulus fluctuations were below 0·3 per cent; possible contributions of stimulus fluctuations to the observed fluctuations in generator potential are, therefore, negligible. Another possibility had to be considered. The fluctuations of generator potential may have been caused by uncontrolled fluctuations in mechanical coupling between crystal stimulator and receptor membrane. If such fluctuations were to increase with stimulus strength, a similar result to that of Fig. 3 could conceivably have been produced.

The following experiment eliminates this possibility. The ending was stimulated with equal mechanical pulses, while its membrane potential was increased to various levels by inward flowing currents. The generator potential increases as a function of membrane potential. The fluctuations in generator potential could thus be studied over a range of generator potential without changing stimulus strength. The fluctuations were found to increase with amplitude of 'polarized' generator potentials (open circles) in the same manner as by increasing the stimulus strength (black circles, Fig. 3). Since under these conditions stimulus fluctuations remained unchanged, the observed increase in fluctuation of generator potential could not have been caused by an increase in fluctuation of mechanical coupling. An alternative possibility that constant fluctuations in mechanical coupling might be multiplied by a factor proportional to the amplitude of generator potential can also be dismissed: it would require that the fluctuation/generator potential ratio be constant instead of progressively diminishing as observed in the experiment of Fig. 4.

It may safely be stated, in conclusion, that the observed fluctuations in generator potential are due to spontaneous fluctuations of activity in the receptor membrane. It is interesting that the receptor membrane of a mechano-sensitive nerve ending resembles in this way the postsynaptic membrane of skeletal muscle, for which evidence has been given that electrical activity is built up statistically[5].

This work was aided by research grants from the U.S. National Science Foundation and the U.S. National Institutes of Health.

NOMENCLATURE AND CLASSIFICATION OF THE TEA PLANT

By Dr. W. WIGHT
Scientific Department, Indian Tea Association, Tocklai Experimental Station, Cinnamara

THE relevance of taxonomic research to the principles of tea cultivation is not generally understood: this article, therefore, directs attention to taxonomic investigations in India and shows their applicability to crop studies.

Botanists describe the tea plant as *Camellia sinensis* (L.). The species was typified by Linnæus with an illustration from Kaempfer[1]. Occidental interest in more recondite classification probably began with Masters[2], who placed the forms now known as *C. sinensis* var. *assamica* (Masters) in a natural category with a distinct type; but he was uncertain whether the remaining forms could be referable to a single type.

Botanists have generally recognized two taxa at varietal level[3], defined largely by leaf-form: the China or type variety (*C. sinensis* var. *sinensis* L.) and the Assam variety (*C. sinensis* var. *assamica* Masters). Typically the China variety is a shrub with more or less virgate stems arising near the ground, 1·0–3·0 m. tall, with relatively small, hard, dark green leaves 3–6 cm. long, with a dull (matt) surface. Typically the Assam variety is a small much-branched tree 10–15 m. tall, sometimes with a trunk one-third its height, with supple light green leaves 15–20 cm. long, with a glossy surface. 'Typical' is in the sense of botanical types of two categories of variants not clearly separated by heredity, and not geographically isolated, these being the implications of varietal status. In practice this classification results in a distinctive Assam variety with a great assortment of forms remaining in the China variety.

The Assam variety is less hardy than the China variety but has bigger yield. Tea made from the two varieties differs fundamentally[4] and one tea cannot be substituted for the other. Subsidiary forms of the Assam variety with dark and light green leaves are cultivated: the dark form might sometimes be hardier, but both make identical tea.

Watt and Mann[5] were probably the first occidental writers to appreciate the need for categories smaller than those defined by botanical nomenclature. Variation of tea leaves is similar to the variation of *Ulmus* leaves. In tea, Watt and Mann described provisional categories of leaf-form within the Assam variety and associated them with regions in north-eastern India. They wondered whether their categories were "natural races or not". Number of leaf veins was emphasized; but this has not proved to be a satisfactory criterion.

Major geographical regions certainly differ in their characteristic tea populations in a way that has not been adequately described, but plants referable to all of Watt and Mann's categories might be found growing together as part of heterogeneous populations in many places; or any one might be found separately in some minor ecological niche on which its separation would depend. Nevertheless there is an unfounded tradition among tea planters that the regional names which Watt and Mann associated with provisional categories define scientifically acceptable types of tea: thus a misleading verbiage has been created, wrongly suggesting agronomically useful types called 'Burma', 'Lushai', 'Naga', 'Manipuri', and so on.

A valuable dissertation by Kingdon-Ward[6] includes the word '*cambodiensis*'. This cannot be accepted as a valid botanical name; but it was, and still is, used provisionally by me for the conceptual type of southern forms some aspects of which have been defined by Roberts, Wight and Wood[7].

Had arrangements been made for their reproduction, then Watt and Mann's leaf-forms could have been established as cultivars[8]. Vegetative propagation has not been practised. Seed is taken from perennial orchards each with a distinctive 'jat' name. Over many years similar, but internally mixed, populations are raised from one orchard: collectively they are known as a 'jat', and this could be regarded as a crude approximation to a cultivar; but one 'jat' might contain all the leaf-forms defined by Watt and Mann.

The naming of cultivars is a practical convenience, but the names can be unperceived obstacles to further knowledge: for example, variables like caffeine content and plant size become referable to names, thus giving relations in which names could, with advantage, be replaced by mathematical variables. Logical treatment of cultivar names is impossible unless they are arrayed in a definite order, and this can be achieved simply by replacing the names with a parameter characteristic of the plant: a suitable parameter would be an organ-frequency, such as number of special cells, or organs of some higher category. Research along these lines shows that the number of phloem parenchyma cells with druses of calcium oxalate in the leaf petiole of tea (conveniently called 'crystal frequency') enables individuals and populations to be placed on a genetically conditioned scale[9]. For simplicity, metrically defined progenies and groups of a crop-plant can be called 'agrotypes'[10]. In what follows attention is directed to the utility of agrotypes of tea defined by crystal frequency.

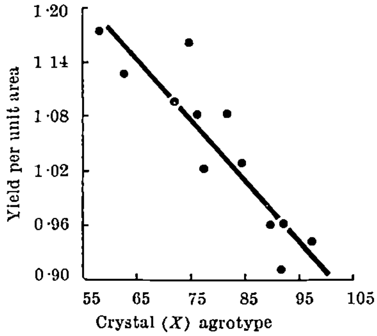

Fig. 1. Relation between the yield per unit area of tea bush and tea agrotypes defined by crystal frequency

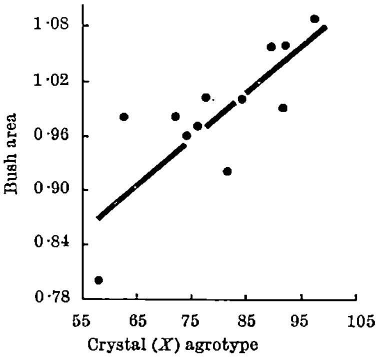

Fig. 2. Relation between the area of a tea bush and tea agrotypes defined by crystal frequency

In Fig. 1, the green weight (kgm.) of tea shoots plucked per square metre of bush surface per year is plotted against the (crystal) agrotype of 12 'jat' populations (cultivars) within the limits of var. *assamica*. Each point is the mean of 1,200 bushes equally divided between four cultural treatments. The correlation coefficient is $-0 \cdot 90$. The surface area of a bush in square metres is plotted against the same base in Fig. 2, the correlation coefficient being 0·78. It could evidently be useful to regard the yield and dimensions of the tea bush as functions of agrotype, and this concept could permit extensions of knowledge that might be impossible with a nomenclatural base of reference. Other definitions of agrotype might sometimes be more appropriate, but the examples suffice to show the utility of a metrical system of classification.

Intergrades between the Assam and the China variety of tea are well known. In practice, intergrades and putative hybrids of plants can be assigned to nomenclatural categories (taxa) by subjective judgment[12,13], showing that a 'specificness' can be recognized. The 'type' of a taxon may be supposed to have maximum specificness. These notions are illustrated by Fig. 3, in which *A* and *B* denote the types of var. *assamica* and var. *sinensis*: between them is an array of leaf-form intergrades (nine in the example) based on an aggregate of vegetative characters in the sense indicated by Li[11]. From *A* to *B* they look less like *A* and more like *B*. Observations which need not be described here show that the general trend of crystal frequency in such an array would be suggested by the column heights of Fig. 3. The array is a 'cline'[13] with special features: specificness different in kind diminishes from both *A* and *B* towards *O*, where it is supposed to be zero. Analogous clines of *Ulmus* were studied by Melville[14], but here another dimension is introduced in the form of crystal frequency. It follows from Fig. 3 that specificness of tea would be inversely related to crystal frequency.

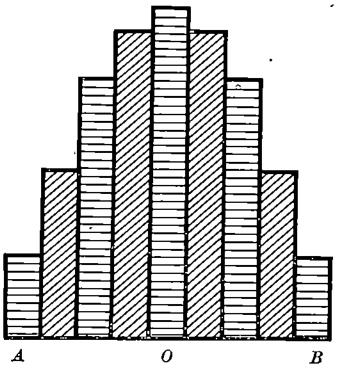

Fig. 3. Column heights indicate the expected trend of crystal-frequency along a cline of intergrades between tea taxa A and B

The 'nominal limits' of a taxon to which intergrades, putative hybrids and introgressants could be assigned might be from A or B to O, or just short of O; 'just short' often being a matter of personal judgment and anyway leaving indeterminate intergrades about O. With more than two taxa a manifold system of clines could be visualized.

While plants in var. *assamica* have typically glossy leaves, some matt plants occur in cultivated populations; but as integrated entities the populations could be within nominal limits of the taxon. Similarly, matt plants are typical of var. *sinensis* but many cultivated populations contain some glossy plants. Leaf-form agrotypes can be defined by the ratio of glossy to matt plants in a progeny population (G/M agrotype). This ratio should increase along the scale from B to A in Fig. 3. But, with O as origin, specificness increases in a positive and a negative direction, signifying two taxa: in one of them G/M would be a measure of specificness, and in the other M/G would be a measure of specificness. A relation between G/M and crystal frequency would be expected to differ in sign between the two taxa. Within nominal limits of a taxon, G/M agrotypes might approximate to a linear function of crystal agrotype, and investigation within the nominal limits of var. *assamica* (Fig. 4) has in fact shown that the two kinds of agrotype can be simply related to each other ($r = 0{\cdot}94$).

The taxonomic origin of tea made from the type variety can be recognized at once by a taster familiar with tea plants; and tea made from solitary matt-leaf plants, not necessarily referable to var. *sinensis*, is often described by tasters as 'chinary'. These observations suggested that some important attributes of tea might be determined by the specificness of the plant from which the tea is made; and this was confirmed by a significant second-order regression between the tasters' scores for 'quality' and the crystal frequency of the plants (unpublished). Thus both quality and yield can be associated with specificness, with the implication of important inter-relations between these three factors, and others such as pubescence[15].

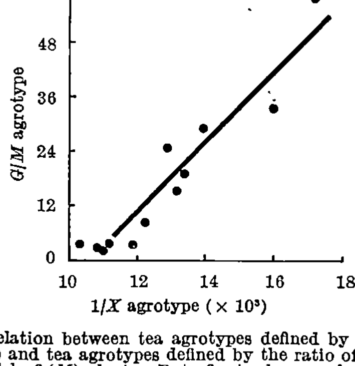

Fig. 4. Relation between tea agrotypes defined by crystal frequency (X) and tea agrotypes defined by the ratio of glossy-leaf (G) to matt-leaf (M) plants. Data for twelve populations within the nominal limits of var. *assamica*, showing that specificness (G/M) is a function of the reciprocal of crystal frequency ($1/X$). Each point is based on 400 bushes per population

Recently introduced mass selection[16], based on pubescence, is likely to alter the crop composition in north-east India; but so far large parts of the crop have approximated generally to crosses and back-crosses between var. *sinensis* and var. *assamica*. Some plantations have an origin in crosses between var. *assamica* and the introduced 'China' material discussed by Masters[2], part of which undoubtedly arose in species hybrids. Work at Tocklai has suggested three possible taxa within the Linnean species (*C. sinensis*) that could have contributed to the crop, and chemical investigations by Roberts *et al.*[7] show that the concept might be widely applicable: it would need to be related to the work of other taxonomists[3,18,19]. There is evidence for introgression from *C. irrawadiensis*[20,21]. Further work at Tocklai (unpublished) shows that each taxon indicated by Roberts *et al.* could be typified by a distinctive floral morphology; and crop surveys based on vegetative features show that the frequency distribution of intergrades between var. *assamica* and the type variety has discontinuities that would be inconsistent with mere varietal status of the two taxa. Although the recognition of taxa in which the crop may have originated is a theoretical necessity, it is to be remembered that taxa have no usefully distinct limits among crop populations: furthermore, there is no clear distinction between wild and cultivated tea[6]. The situation necessitates metrical classification, and it is possible for this to be complementary to botanical nomenclature.

While I am responsible for the point of view of the article, my ideas over several years have been clarified by discussions with Mr. P. H. Carpenter, Dr. E. K. Woodford, Dr. K. Biswas, Mr. J. R. Sealy, and Dr. G. Watts Padwick, whose interest and help it is a pleasure to acknowledge.

LETTERS TO THE EDITORS

RADIATION BIOLOGY

Variation of Sensitivity to Ionizing Radiation with Age

The relation between the long-term effects of radiation and ageing has been the subject of much investigation in recent years, but little quantitative work has been done on the variation with age of the effects produced by a given dose of radiation. Using a single dose, Abrams[1] found a maximum mortality-rate in mice 4 weeks old. Hursh and Casarett[2] measured the *LD*50 in rats of different ages, and found a decrease with age in the latter period of life; somewhat similar results were obtained by Sacher[3] for mice. We are carrying out a systematic study[4] of the long-term effects of radiation in mice, with particular reference to the dependence of these effects on age. As part of this work, we have investigated the variation of sensitivity with age, using as a criterion of radiation damage the *LD*50 at 30 days.

The animals used were an inbred strain of albino mice (*SAS*/4), with a mean life of about 110 weeks. Except for the youngest age-groups, which were bred in our animal house, the mice were introduced into the colony at the age of 3 weeks. One week before irradiation they were divided randomly into cages of 8, the mice in every fifth cage serving as controls. About 400 mice—all of the same age—were used in each age-group, this number being divided into four dose groups of about 80 mice each, with the remaining 80 as controls. The numbers of males and females were about equal. When the mice reached the age for irradiation, they were given a single whole-body exposure of X-rays. The source of radiation was the 15-MeV. linear accelerator at St. Bartholomew's Hospital, and the dose-rate was about 400 r./min.

After exposure, the mice were returned to their cages, and deaths occurring during 30 days after the exposure were recorded daily. Regression lines of the mortality-rate versus dose were then plotted, using the method of probit analysis, and the *LD*50 values thus determined.

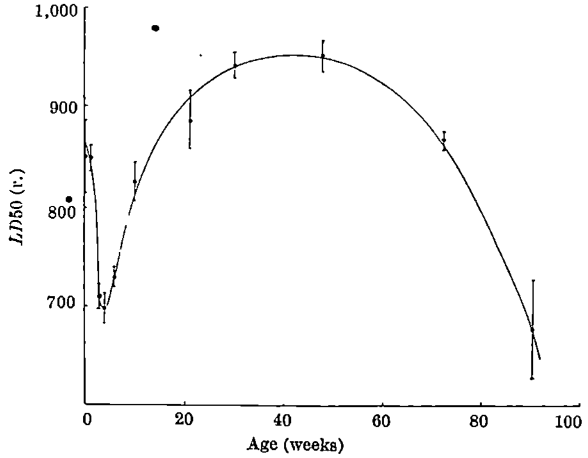

Fig. 1. *LD*50 for *SAS*/4 mice at 30 days as a function of age

Table 1 and Fig. 1 show the results obtained for mice over a range of ages from one day to ninety weeks. The standard error for each value of the *LD*50 is given in Table 1 and is indicated in Fig. 1 by vertical lines; it is about 2 per cent, except for the youngest and the oldest age-groups, where smaller numbers of animals were available. When comparing these results with those of other workers, note should be taken of the relative biological effectiveness of the 15-MeV. X-rays; in a separate experiment we have found that the relative biological effectiveness for our radiation, relative to 250 keV. X-rays, is 0·81.

Table 1. *LD*50 AND COEFFICIENT OF VARIATION FOR ALL MICE AS A FUNCTION OF AGE

Age (weeks)	*LD*50 (r.)	Coefficient of variation (per cent)
0·14	850 ± 37	11·9 ± 2·2
1	850 ± 13	9·6 ± 1·3
3	709 ± 13	19·4 ± 2·0
4	698 ± 16	25·2 ± 2·3
6	728 ± 10	15·5 ± 1·2
10	826 ± 20	18·8 ± 2·1
21	887 ± 30	15·2 ± 2·6
30	942 ± 13	13·7 ± 1·4
48	952 ± 15	14·9 ± 1·9
72	866 ± 9	12·2 ± 1·1
90	676 ± 50	31·0 ± 9·0

The median age at death decreased slightly with increasing dose (about 1 day/100 r.) but showed scarcely any variation with the age of the mice. For a dose equal to the *LD*50, the median age was 11·7 ± 0·8 days.

The *LD*50 values were also calculated separately for males and females and the results are given in Table 2. It is seen that although, in general, the variation of *LD*50 with age is the same for both sexes, there are some characteristic differences. The females appear to be slightly more sensitive to radiation when young, but after the age of 10 weeks they persistently show a greater resistance to radiation, the *LD*50 at a given age being about 50 r. greater than for the males. It is interesting that the expectation of life of females of this strain is about 4 weeks shorter than that of males.

Table 2. *LD*50 FOR MALE AND FEMALE MICE AS A FUNCTION OF AGE

Age (weeks)	Males (r.)	Females (r.)
3	702 ± 18	721 ± 16
4	708 ± 22	690 ± 22
6	748 ± 13	708 ± 12
10	863 ± 48	802 ± 16
21	861 ± 39	912 ± 51
30	907 ± 14	968 ± 27
48	935 ± 20	974 ± 27
72	855 ± 14	877 ± 11
90	641 ± 35	711 ± 50

Table 1 contains the coefficient of variation, that is, the standard deviation for each measurement divided by the *LD*50, which is a measure of the uniformity of the response. During most of life this coefficient varies very little. The high value at 90 weeks may be spurious, but the peak at about 4 weeks appears to be genuine, indicating a greater variability in the population at that age. This was confirmed by another observation. In our main experiment, on the long-term effects of radiation, we irradiated the mice at 4 weeks of age and we have obtained *LD*50 values at that age on several occasions during the past two years and for different batches of mice. The results show a considerable scatter in the *LD*50 values, ranging from 620 to 785 r. (the value given in Table 1 is the mean of these determinations). A similar experiment with older mice showed a very good reproducibility of the *LD*50 values. There was no epidemic or other cause to explain these findings, and we must thus conclude that at about 4 weeks, when the sensitivity of the mouse to radiation is highest, there is also a large degree of variability. This is one week after weaning, and so is a period of adaptation to a different diet and environment.

Our results clearly show that there is a considerable variation of sensitivity to radiation with age throughout life, but particularly so at a young age. None of the theories which have been put forward to explain the effects of radiation accounts for this variation. Blair's[5] theory predicts a steady decrease of the *LD*50 with age, proportionately to the remaining expectation of life. The last part of the curve of Fig. 1 does indeed follow the trend of the expectation of life curve, but it is clear that at younger ages there appears to be another intrinsic factor, which affects the sensitivity to radiation. Experiments aimed at elucidating the nature of this factor are now in progress.

Although it is imprudent to extrapolate from mice to men, and from acute to long-term effects, the variation of radiosensitivity with age observed by us may be a general effect, and in that event it may have to be taken into account both in radiotherapy and in setting maximum permissible doses.

PHYSIOLOGY

Contraction and Relaxation in Smooth Muscles of Lamellibranch Molluscs

MUSCLES such as the smooth adductors of lamellibranch molluscs maintain a state of tonic contraction with very little expenditure of energy, because normally tension persists long after stimulation has ended and the active state has decayed to zero[1]. As determined by the quick-release method[2], the intensity of the active state at any instant is indicated by the isometric tension the muscle can re-develop at that instant. The tension present after the active state has decayed to zero may be called passive tension. (The latter can readily be distinguished from resting tension, which only appears when the muscle has been stretched beyond the length it can assume in the animal's body[3].)

We have found that in a twitch response of the anterior byssus retractor muscle of *Mytilus*, the decay of tension can be two orders of magnitude slower than that of the active state, and this also applies when the active state is prolonged by stimulating the muscle for several seconds either with direct current or with acetylcholine[4]. From experiments with a variety of molluscan muscles, but particularly with the anterior byssus retractor muscle of *Mytilus* (all of which contain filaments showing paramyosin structure[5]), it would appear that their behaviour can be explained on the following assumptions : (1) that the tension developed during the active state is due to the formation of linkages in a sliding-filament actomyosin system[6], and that linkages are also made which involve a second system, characterized by the presence of filaments with paramyosin structure ; (2) that these latter linkages (to be called tonic linkages) break at a very slow rate and are responsible for the phenomenon of passive tension ; (3) that activation of inhibitory nerves increases the rate at which the tonic linkages break.

This explanation does not accept the 'catch mechanism' hypothesis, which holds that these muscles can maintain tension indefinitely without any expenditure of energy[7], because we find that in the absence of further activation tension decays to zero, and that a steady level of tension can only be maintained by periodic re-excitation of the muscle, that is, by a tetanic mechanism. The object of this communication is to summarize some of the physiological evidence in support of our hypothesis.

When the anterior byssus retractor muscle of *Mytilus* is stimulated with shocks several times threshold value, both excitatory and inhibitory nerves are activated and tension cannot be maintained for prolonged periods[4] (also Lowy, J., and Millman, B. M., unpublished results). Reduction of strength or frequency of stimulus gives a well-maintained tonic contraction (Fig. 1, *a* and *b*), and here inhibitory nerves are probably not activated. In this case the

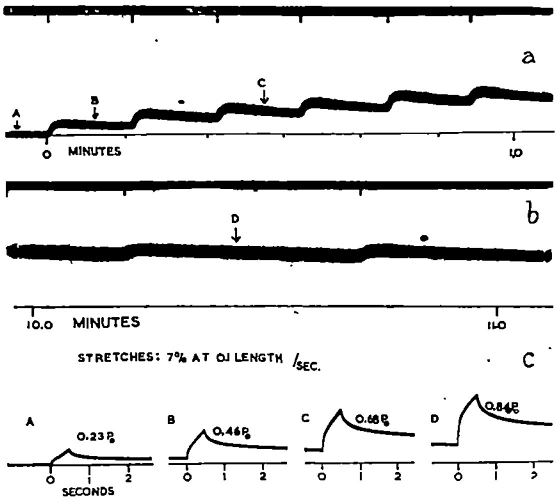

Fig. 1. (*a*) Anterior byssus retractor muscle of *Mytilus* stimulated directly by square wave pulses (15 V., 2 msec.) once every 10 sec. ; record of tension, increase upwards. (*b*) Same experiment ; after 4 min., frequency of stimulation had been reduced to one shock every 30 sec. ; a high level of tension (4 $kgm./cm.^2$) was maintained ; in this experiment stimulation was continued for 30 min. (*c*) In similar experiments the same muscle was stretched (within a range of muscle lengths where resting tension was negligible) at the points *A*, *B*, *C*, *D* indicated in *a* and *b* ; this revealed that resistance to stretch increased during the first 10 min. by a factor of about 4

resistance of the muscle to stretch increases with time (Fig. 1, *c*), suggesting (on our hypothesis) that the number of tonic linkages brought into action reaches a maximum only gradually.

Rapid stretch (at constant speed) of a muscle after the active state has decayed to zero, but at a time when some passive tension is still present, produces a large transient tension which takes several minutes to decay to zero. In the anterior byssus retractor muscle of *Mytilus*, the decay curve can be resolved into three exponential components with half-decay times of about 0·17, 2·2 and 45 sec. (Fig. 2). The time constants of the first two components are very close to those of the two exponential components in the stress relaxation curves of slow striated muscles[8]. As the filaments in striated muscle show no paramyosin structure, these two components are probably due to the actomyosin system. We have found the third component only in molluscan smooth muscles which have filaments with paramyosin structure and hold passive tension. The third component has a decay time of the same order of magnitude as isometric twitch tension, and is very likely due to the presence of tonic linkages. This idea is supported by the observations that after stimulation which also activates inhibitory nerves (or after treatment of the anterior byssus retractor muscle of *Mytilus* with 5-hydroxytryptamine which may act here as the inhibitory transmitter[9]), the third component is absent whereas the other two components remain unchanged; and that relaxation in an isometric twitch is accelerated whereas the time of rise of tension is not appreciably affected.

Further evidence for the presence of two systems comes from experiments in which the anterior byssus retractor muscle of *Mytilus* was stretched (at constant speed) during stimulation. If the stimulation also activates inhibitory nerves (and thus we assume diminishes the number of tonic linkages in existence at any instant) the form of the stretch curve resembles that given by tetanized frog sartorius muscle: a rapid increase in tension, followed by a more gradual rise (Fig. 3, *a* and *b*). It is conceivable that in both cases the fast phase is due to stretching of only the series elastic element, the linkages of the actomyosin system being extremely rigid. The point of inflexion of the curve could mark the stage at which these linkages break ('give'). The following slow phase might then represent the re-making and breaking of actomyosin linkages, and in the anterior byssus retractor muscle of *Mytilus* possibly also of some tonic linkages. During stimulation which does not activate inhibitory nerves, the tension produced during the slow phase of the stretch curve in the anterior byssus retractor muscle of *Mytilus* is appreciably greater (Fig. 3, *c*). This, and the differences in form of curves 3 *b* and 3 *c*, we consider to be due to the presence of tonic linkages.

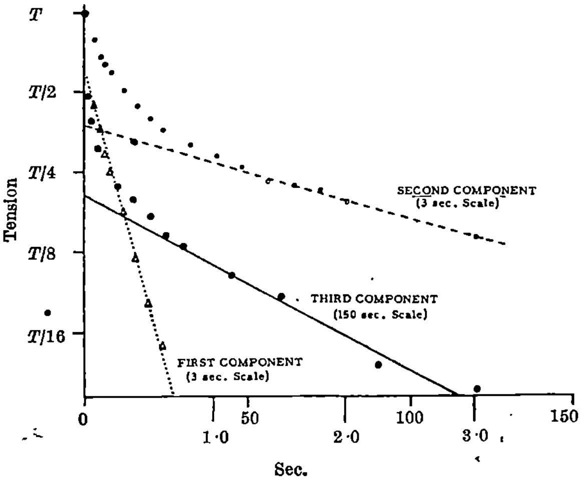

Fig. 2. Decay of tension produced by stretching the anterior byssus retractor muscle of *Mytilus* 10 per cent of its length at 0·24 length/sec., when a small amount of passive tension was present; the muscle was stretched within the range of lengths where resting tension was negligible. ●, Course of decay of tension; ○, decay of tension minus third component; △, decay of tension minus second and third components

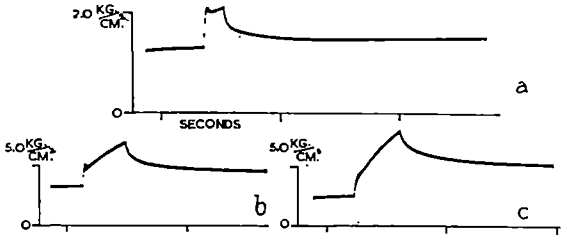

Fig. 3. (*a*) Sartorius of frog (0° C.) stretched 8 per cent of its length at 0·4 length/sec. during tetanic stimulation; isometric tension level, 1·3 kgm./cm.²; maximum tension above isometric produced during stretch, 0·8 kgm./cm.²; (*b*) anterior byssus retractor muscle of *Mytilus* (20° C.) stretched 10 per cent of its length at 0·24 length/sec. during stimulation that also activated inhibitory nerves; isometric tension-level: 3·5 kgm./cm.²; maximum tension above isometric produced during stretch: 3·8 kgm./cm.²; (*c*) same muscle and extent and speed of stretch as in (*b*); during stimulation that did not activate inhibitory nerves (12 volts direct current); isometric tension-level, 2·4 kgm./cm.²; maximum tension above isometric produced during stretch, 5·5 kgm./cm.²

Finally, the prolonged existence of these linkages is indicated by the observation that an anterior byssus retractor muscle of *Mytilus* stretched after stimulation (which does not activate inhibitory nerves) has ended, but at a time when some passive tension is still present, gives a stretch curve similar in form to that shown in Fig. 3 *c*. As might be expected, the amount of tension produced by such a stretch decreases with time after cessation of stimulation—as does passive tension.

Details of this work will be published elsewhere. The hypothesis put forward here owes much to discussions with Dr. Jean Hanson and is consistent with unpublished structural information obtained in this Laboratory by one of us (J. L.), Dr. Jean Hanson and Mr. G. F. Elliott.

Quantitative Estimation of Amineoxidase

THE evidence linking brain function to amineoxidase activity[1] has stimulated a large production of papers[2]. The disagreements that have ensued[2] might well be a measure of the interest in these aminases. However, we attribute much of the discord to the accepted method of studying these trace enzymes, namely, respirometry. The present communication shows that respirometry is an erratic yardstick as compared with the measurements of ammonia (or primary amine) released by the amineoxidase reaction. The ease and accuracy of these latter micromethods have been shown previously[3-9].

For this study the currently popular monoamineoxidases were selected. In all probability, however, our conclusions apply to the entire group of enzymes concerned with oxidative deamination.

The reaction catalysed by monoamineoxidase has been written as follows[8]:

$$RCH_2NH_2 + H_2O + O_2 \rightarrow RCHO + H_2O_2 + NH_3$$

Therefore, in the presence of catalase, one molecule of oxidized substrate should release one molecule of ammonia and take up one atom of oxygen. That this is by no means always the case is shown by the two sets of 85 analyses summarized in Fig. 1. The two tests were performed concomitantly with a method presented previously[7]. Rat liver homogenate in various concentrations provided the enzyme and tyramine hydrochloric acid (100 μM) in potassium phosphate buffer (pH 7·4, μ0·1) completed the reaction mixture. The temperature was 37° C. and the atmosphere was oxygen. The broken line indicates the stoichiometric relationship between net oxygen uptake and net ammonia evolution. Almost all the data fell below the line, showing that more oxygen was taken up than can be attributed to the monoamineoxidase reaction alone. An excessive oxygen uptake was found also when salts of tryptamine, 5-hydroxytryptamine, epinephrine, norepinephrine, phenylethylamine, hydroxytyramine or benzylethylamine were used as substrates.

Several rat organs were tested in this fashion. The oxygen uptake was excessive to a variable degree. For example, in one experiment, liver and brain homogenates were compared. The O/NH$_3$ ratio for liver was 3·7 and for brain 1·9. Dark pigments were always formed when liver was tested, but these could not be discerned with brain.

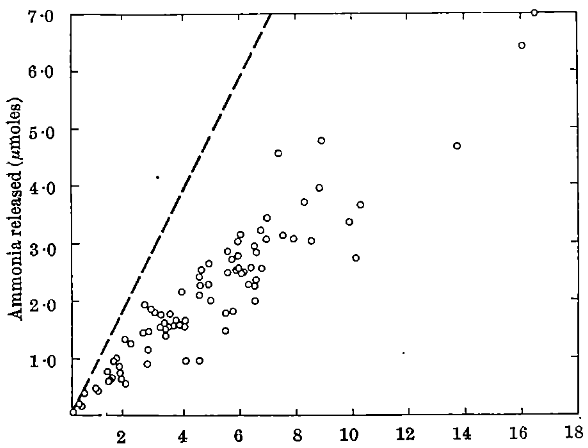

Fig. 1

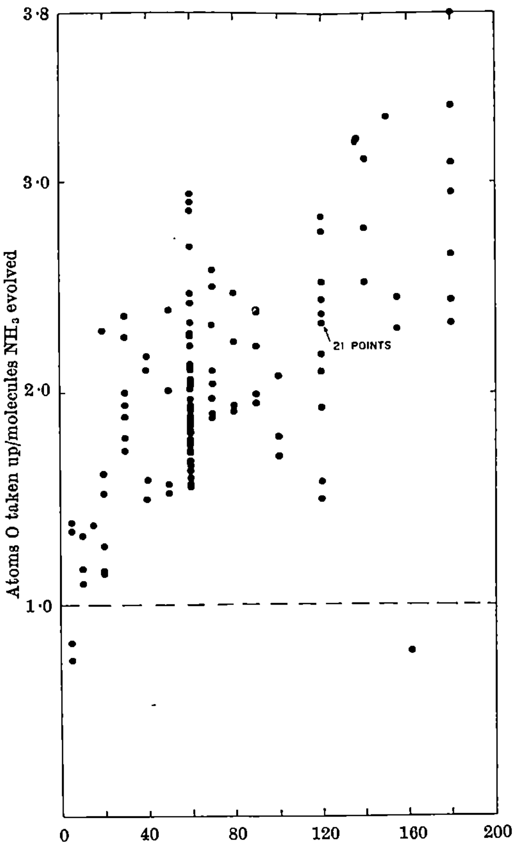

Fig. 2

Longer periods of incubation resulted in more pronounced oxidative excess. Fig. 2 shows that during the first few minutes of the reaction a surprisingly low oxygen uptake relative to the ammonia evolved may be observed. The broken line again indicates the stoichiometric relationship. Indeed, in experiments not illustrated here the O/NH$_3$ ratio was 0·3. (We had shown earlier[3] that no fixation of added ammonia can be detected under the conditions of these tests. In addition, whenever a limited amount of substrate was allowed to be completely deaminated, the recovery of ammonia was quantitative, while the oxygen uptake has varied.) Tentatively we have attributed this low O/NH$_3$ ratio to the lower sensitivity of the respirometer as compared with the ammonia measurement[3,5,7]. It has to be conceded, however, that these results might indicate the existence of an entirely separate deamination reaction which precedes oxidation. Also, the large spread of the data presented here suggests that the two processes might not be entirely linked. Regardless of the favoured explanation, it is evident from Fig. 2 that the uptake of oxygen became increasingly higher relative to evolution of ammonia with the advent of time.

Since secondary reactions contribute such a large proportion of the oxygen uptake, they may well determine the final score in studies of activation and inhibition of this enzyme. The discrepancies between two studies of intracellular localization[4,9] are probably due to differences in technique and suggest that respirometry might yield a distorted picture of this enzyme's partition in tissues.

An investigation was aimed at possibly eliminating the excess oxygen uptake. Several inhibitors were tested for their capacity to diminish specifically the oxygen uptake, but these experiments will be published separately. It is sufficient for the present argument to note that in experiments overlapping those of Creasey[10] there was essential agreement: precise addition of selected inhibitors may force the oxygen uptake almost to obey stoichiometry.

In conclusion, it seems obvious that the techniques for determining ammonia[3,5,7] would provide a more specific yardstick for the monoaminoxidase activity of tissues than does the popular respirometry. The latter may be coached to yield almost stoichiometric results, but the necessary chemical *tour de force* produces a complex and rigid system.

A Rare Variant of B in a Human Blood Sample belonging to Group AB

During routine blood-group examination of healthy persons, one of the blood samples tested was found to exhibit unusual properties. The potent anti-A and anti-B test sera used agglutinated the erythrocytes quite well, whereas the serum of this AB blood (subgroup A_2B) reacted weakly at room temperature with B cells. The irregular agglutinin was no more active at 37° C. and reacted better at 4° C. (titre 8) than at 20° C. No auto-agglutination was observed. At 4° C. the serum agglutinated all of 15 B but neither 20 A nor 15 O cells samples simultaneously tested. The B specificity of this agglutinin was confirmed by absorption experiments with B erythrocytes and with purified blood group B substance. The B specificity of the agglutinogen in Mrs. Br.'s cells was ascertained by studying the action of several A and AB sera on them; the agglutinating action of A sera did not occur after absorption by normal B cells or purified B substance. The 'Br.' cells significantly absorbed the anti-B agglutinin in normal A sera, but less, however, than did A_2B cells used as control, and released it after elution more completely than did these A_2B cells. The 'Br.' cells were agglutinated by anti-H eel serum nearly as well as group O cells. The 'Br.' saliva inhibited the anti-A agglutinin at a high dilution, and the anti-B and anti-H agglutinins when more concentrated. Its inhibitory action on anti-H was not weaker than that of an A_2 control.

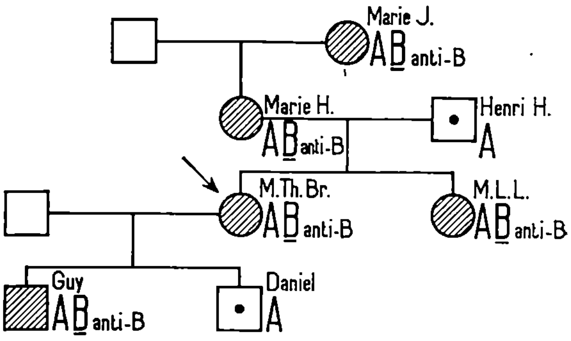

Fig. 1

This unusual subgroup was found in the blood of four other members of Mrs. Br.'s family. The four samples, belonging to the AB group, showed the same serological pattern as the 'Br.' blood. The irregular anti-B agglutinin was present in their serum, at a titre of 4 to 16 (at 4° C.). The four samples of saliva contained A, B and H substances but did not inhibit Mrs. Br.'s anti-B agglutinin.

The variant of B here described is quite different from the recently published cases of very weak B agglutinogens[1-4]. It would probably more likely resemble the case reported by Formaggio[5] (whose serum contained also an anti-B agglutinin) and perhaps those found in Pakistan by Boyd[6]. In considering its serological character, it appeared to us that it behaved in a way very similar to that of A_3 within the A group.

Pressor Amines and Neuroblastoma

Isaacs, Medalie and Politzer[1] describe three cases of neuroblastoma in children in whom the 24-hr. excretion of noradrenaline in urine was 200–300 μgm. This is not a vast amount but may be abnormally high. The suggestion was that neuroblastoma is a tumour which, like phæochromocytoma, secretes pressor amines. On March 23, 1959, I obtained, by courtesy of Dr. P. T. Bray, a specimen of tumour infiltrating the left kidney, taken by Mr. H. Wade from a boy aged nine years at East Glamorgan Hospital, Church Village, Glamorgan, and kept frozen. This tumour was reported by the histopathologist to be typical neuroblastoma; the whole specimen weighed approximately 450 gm. of which some 300 gm. was tumour. 50 gm. was excised from the region which had been used for histology, cut up fine and homogenized with 50 ml. of water containing 5 mgm. ascorbic acid. This was spun at 3,000 r.p.m. for 15 min. and the supernatant examined on the blood pressure of the spinal rat injected with atropine and a ganglion blocker. Such a preparation responds to adrenaline 0·1 μgm., noradrenaline 0·05 μgm. or 5-hydroxytryptamine 3 μgm. with a pressor response.

The average of three assays indicated that the supernatant contained pressor activity equivalent to 0·25 μgm./ml. of noradrenaline. The supernatant also caused the smooth muscle of isolated guinea pig to contract smartly, in the presence of atropine sulphate 10^{-7} and mepyramine malleate 10^{-7}. This activity was reduced by lysergic acid diethylamide *pari passu* with that of added 5-hydroxytryptamine. The pressor action in the rat was also reduced but not abolished by *LSD*25. A dibenamine-like drug in a dose sufficient to abolish the pressor action of adrenaline, reduce that of noradrenaline but only in a dose sufficient to abolish the pressor action of adrenaline, reduce that of noradrenaline but only slightly affect that of 5-hydroxytryptamine reduced the effect of the extract.

The conclusion reached is : (*a*) this neuroblastoma contained pressor substances ; (*b*) these include noradrenaline and possibly adrenaline and 5-hydroxytryptamine ; (*c*) the amount is small compared with phæochromocytoma.

Histochemical Changes in the Epiphyseal Cartilage during Rickets

In a previous communication[1], a method was described for staining the sites of the initiation of calcification in bone and teeth. This method consisted in treating the tissues with hot pyridine for 24 hr. prior to decalcification and then staining with sudan black. Sudan black stained the matrix around the hypertrophic cells in the epiphyseal cartilage just before these cells are removed by capillary erosion.

In order to test the hypothesis that the sudanophil material was concerned with calcification, rats with florid rickets have been examined. They were put on the Steenbock–Black diet[2] when they weighed 50–60 gm. ; 28 days later some were killed and others received one dose of 30 I.U. of vitamin D and were killed at daily intervals thereafter. The upper tibial epiphysis was examined by the method described above.

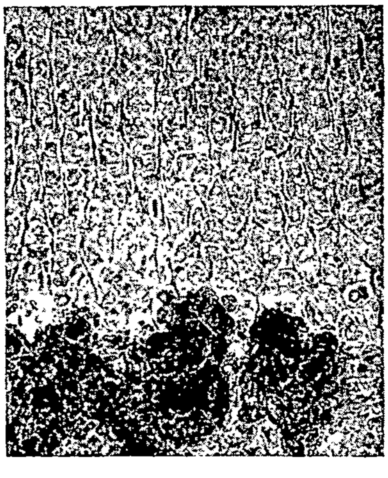

Fig. 1. Upper tibial epiphysis of rachitic rat, stained with sudan black after treatment with hot pyridine. No staining of the matrix between the hypertrophic cells is to be seen. (× *c.* 150)

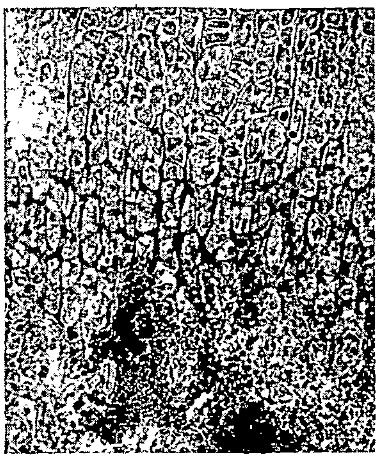

Fig. 2. Upper tibial epiphysis of rachitic rat, 7 days after dosage with 30 I.U. of vitamin D. Stained with sudan black after treatment with hot pyridine. Note re-appearance of sudanophil material in the matrix between the hypertrophic cells. (× *c.* 150)

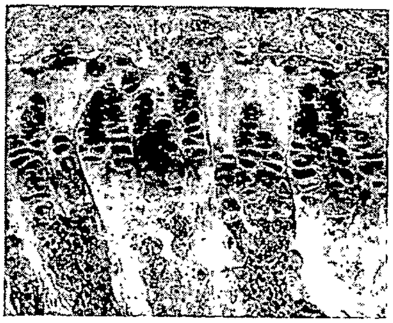

Fig. 3. Upper tibial epiphysis of old rat stained with sudan black after treatment with hot pyridine. The cartilage matrix does not stain, but the cartilage cells are filled with sudanophil granules. (× *c.* 150)

No sudanophil material was found in the epiphyseal cartilage of rats with untreated rickets (Fig. 1), but after dosage, the sudanophil material returned to the cartilage (Fig. 2) at the same time as calcification recommenced, as visualized by the von Kossa technique. In later stages, the material stained with silver extended deeper into the metaphysis as healing progressed ; but at all times sudan black stained only the matrix around the cells where calcification was starting.

These observations confirm the previous conclusion that the sudanophil material is intimately concerned with calcification. Experiments to be reported elsewhere have shown that under appropriate conditions the methylene blue extinction of the sudanophil material is lower than *p*H 2·6, indicating a highly acid mucopolysaccharide.

The upper epiphysis of the rat tibia does not close when growth stops, but is sealed off by a bony plate. The cartilage matrix no longer stains with sudan black, but the cartilage cells are full of sudanophil granules (Fig. 3). The same is often seen in the hypertrophic cells of rachitic cartilage, and possibly the cells store this substance when calcification does not or cannot take place.

Electrophoretic Patterns of the Serum Proteins of Sheep infected with *Hæmonchus contortus*

The subcutaneous injection of living *H. contortus* into worm-free sheep appeared to provide partial protection against subsequent challenge[1]. Changes in the electrophoretic pattern of the serum proteins might be expected[2–6], and the appearance of the pattern has been followed.

Sera from sheep, untreated control (3), injected with dead larvæ (3), and injected with live larvæ (3) were collected prior to injection, after two injections and subsequent to challenge. No change in the electrophoretic pattern by filter paper electrophoresis was apparent. In a more detailed quantitative study by column electrophoresis[7] two of the animals infected with live larvæ showed a slight (1 per cent) increase in β-globulin. No increase in γ_1- or γ_2-globulin was observed.

The experiment was repeated with a further six sheep all of which became refractory to re-infection as a result of successive injections followed by challenge doses. The electrophoretic patterns of the serum proteins from three animals showed a pronounced intensification of the β-globulin. There was a less-marked change in one animal; and the pattern in the two others remained unchanged.

Pharmacology of a Tranquillizing Principle in *Paspalum scrobiculatum* Grain

Paspalum scrobiculatum Linn. (Fam. Gramineae; name in Marathi language, *harik*) is cultivated in various parts of India for the grain, which forms the staple diet of the poor rural population. One variety of this plant yields a toxic crop after a favourable rainfall. The toxin is believed to reside in the husk of the grain. The grain of such a crop is detoxified before use by a special process.

The grain was kept in ethanol at room temperature for 1–2 days. The ethanol extract was evaporated to dryness by heating on a water-bath. The dry residue was thoroughly mixed with dilute hydrochloric acid. The dilute acid was then separated from the undissolved portion and dried by heating on a water-bath. The residue or active fraction was dissolved in distilled water before use.

The original active substance is soluble in boiling water, acidified water, ethanol, chloroform and ether. It can be partly extracted from alkaline aqueous phase by ether. Thus it behaves like an alkaloid. It is biologically active after keeping in strongly acidic or alkaline media even at 100° C. Aqueous solution of the active fraction (which appears crystalline under the microscope) gives green fluorescence in ultraviolet light. Two samples of grain gave yields of 0·025 and 0·066 per cent of the active fraction respectively. The active fraction does not give the colour reaction suggested by Sundaram Ayyar and Narayanaswamy[3]. (In their animal experiments those authors observed only tremors and death.)

Various samples of grain (comprising from 1 to 50 gm.) and the various fractions of extraction were added to the diet of 11 dogs in 53 experiments. The active fraction, prepared from samples of 1–50 gm. of grain, was also administered by intravenous or intraperitoneal injection into 6 dogs in 33 experiments.

Oral administration produces tranquillity and lack of interest in the environment. The dogs sit quietly, crossing the forelimbs and looking vacantly into space. Hostile dogs become much less aggressive. Larger doses cause tremors, rigidity of face, trunk and limbs not unlike human Parkinsonism. There was no miosis of the eye in these animals. The effects usually persist for 6–8 hr.

In 5 dogs and 2 cats, after anæsthesia, intravenous injection of the active fraction did not produce any relevant change in blood pressure and respiration, except depression of the carotid sinus reflex in 2 dogs and 1 cat.

In 10 rabbits, 11 guinea pigs, 4 cats and 21 albino rats, the active fraction produced definite tranquillity. In rabbits larger quantities produce clonic convulsions and death.

The effect of the active fraction on hexobarbitone sleeping time was studied in mice, following the technique of Brodie *et al.*[1]. The hexobarbitone sleeping period was significantly (*t*-test, $P < 0{\cdot}01$) prolonged in mice after injection of the active fraction (Table 1).

Like reserpine and chlorpromazine, the active fraction produces tranquillity and symptoms of 'Parkinsonism' in dogs. Unlike chlorpromazine, reserpine produces parasympathomimetic effects and release of 5-hydroxytryptamine from the central nervous system. The active fraction does not produce clear-cut parasympathomimetic effects (such as

Table 1. HEXOBARBITONE SLEEPING PERIOD IN MICE
Hexobarbitone, 100 mgm./kgm. intraperitoneally. Active fraction given ½ hr. before hexobarbitone

Drug	Source of active fraction	Sleeping time (min. ± *S.D.*)	No. of mice used
Control (hexobarbitone)		23 ± 6·5	17
Active fraction + hexobarbitone	6 gm. grain	47 ± 23·4	6
	12 gm. grain	101 ± 38·0	14
	24 gm. grain	123 ± 12·9	7
Active fraction + hexobarbitone		53 ± 8·3	12
Active fraction + hexobarbitone 2 days later		50 ± 11·3	11

Table 2. HEXOBARBITONE SLEEPING PERIOD IN MICE

Reserpine (5 mgm./kgm.) administered 1 hr. before hexobarbitone (100 mgm./kgm.) administered intraperitoneally. Only hexobarbitone given next day to assess the residual effect of reserpine. Chlorpromazine 2·5 mgm./kgm.

Drug	Sleeping time (min. ± *S.D.*)	No. of mice used
Control (hexobarbitone)	19 ± 7·3	32
Reserpine + hexobarbitone	60 ± 14·0	21
Hexobarbitone, 1 day later	17 ± 6·7	32
Reserpine + hexobarbitone, 2 days after first injection	17 ± 6·0	22
Chlorpromazine + hexobarbitone	45 ± 7·2	13
Chlorpromazine + hexobarbitone, after 2 days	44 ± 11·8	12

miosis). A much simpler experiment is therefore to test whether it releases 5-hydroxytryptamine from the central nervous system. Mice received intraperitoneally chlorpromazine or reserpine or the active fraction, followed by hexobarbitone, and their sleeping time was noted. Two days later the same mice received the same substance, and hexobarbitone and the effect on sleeping time was again noted.

The active fraction and chlorpromazine when re-administered after 2 days were still active in prolonging the hexobarbitone sleeping time, whereas reserpine, which depletes the central nervous system of 5-hydroxytryptamine for about 5 days (Shore *et al.*[2]), was inactive in prolonging sleeping period in mice after 2 days (Table 2).

Further work is in progress.

Spore Germination in *Agaricus campestris* L. ex Fr.

THE presence of growing mycelium of *Agaricus campestris* in medium containing spores of this fungus has been shown to stimulate germination[1,2]; but there are no reports of a detailed analysis of the effect.

Recent experiments here have shown that a volatile metabolite secreted by the mycelium is a stimulating factor. This was first demonstrated by showing that spores held on a nutrient medium in the air above actively growing cultures of the fungus, or above medium taken from such cultures, germinated better than those held above uninoculated control medium.

The presence of a volatile metabolite was confirmed by drying gases from cultures with phosphorus pentoxide, and passing them through a container cooled in liquid air. A crystalline product was obtained which was a volatile liquid at room temperature. The germination of spores on nutrient media was strongly stimulated by the presence of an aqueous solution of this material in the same container, but not in contact with them.

Analysis of this material by means of a mass spectrometer has shown the presence of an olefin which is probably 2 : 3-dimethyl-1-pentene. No other compound has been detected during this analysis. It has not yet been possible to obtain synthetic material for testing, but it appears likely that this substance is the stimulating factor.

These observations seem of interest in relation to the many reports[3] of the production of unsaturated hydrocarbons by plant organs. In many of these cases the gas has been identified as ethylene, but the tests used have not usually been sufficiently rigorous to exclude the presence of other olefins[4]. Trimethylethylene has been reported as a self-inhibitor of germination of spores of *Puccinia graminis* var. *tritici*[5]. These observations may also relate to the reports of a volatile substance which inhibits strand formation and fruit-body formation if it is allowed to accumulate in mushroom beds[6–8].

The work is continuing and a detailed report will be published elsewhere.

BIOCHEMISTRY

α-Helices and a New Polypeptide Fold in Poly-β-Benzyl-L-Aspartate

IN Moffitt's expression for the variation of the optical rotation of an L-polypeptide in the α-helical form with wave-length[1,2], the constant b_0 has been found to have values between −400 and −700 deg. cm.^{2}/decimole; the negative value is certainly associated with a right-handed screw sense in poly-L-alanine[3]. Recently, values up to 631° have been reported for poly-β-benzyl-L-aspartate ($[CO.NH.CHCH_2CO.OCH_2C_6H_5]_n$) in chloroform solution by Blout and Karlson[4]. This positive value of b_0 may indicate either the 'structural' anomaly of a left-handed screw sense, or alternatively an 'optical' anomaly due to interaction between peptide and side-chain chromophores or consequent upon some minor structural peculiarity. We have confirmed the anomalous result and have examined the polymer by a variety of techniques.

Direct evidence as to the configuration of the polymers exists only for the solid state. Films cast from chloroform solution and oriented by stroking give an X-ray diffraction pattern which is undoubtedly that of the α-helix, with a meridian reflexion at 1·5 A.

We have measured the residue rotation and calculated b_0 (assuming λ_0 to be 2120 A., as in poly-γ-

benzyl-L-glutamate) for a number of preparations of poly-β-benzyl-L-aspartate of different molecular weights, in solvents of different polarity. A representative selection of these results is given in Table 1, together with viscosities measured in dichloracetic acid, which give a measure of molecular weight. In dichloracetic acid the values of b_0 and $[R_{\text{vac.}}]$ are not correlated with molecular weight. In *m*-cresol these quantities change greatly in magnitude and also in sign, and in chloroform a less dramatic but still significant change may be seen. In both these solvents a limiting value has been approached in the two specimens of highest molecular weight. We take this to mean that in dichloracetic acid the polymer is in a random, solvated coil in spite of the high value of b_0. In chloroform and to a lesser extent in the more polar *m*-cresol, a fraction of the polymer must be in a helix, the specimens of higher molecular weight being almost entirely in this form. This is reasonable, but the values of b_0 are unlike those in poly-γ-benzyl-L-glutamate ($[CO.NH.CHCH_2CH_2CO.OCH_2C_6H_5]_n$) in three respects. As mentioned above, b_0 is positive in the helix form. Secondly, it differs considerably from zero in the random coil form and finally it changes sign and becomes numerically very much greater in films cast from a non-polar solvent. Films of poly-γ-benzyl-L-glutamate are found to have a value of b_0 of approximately the same magnitude (and negative sign) as solutions containing α-helices of that polymer. It is evident that some kind of optical anomaly is present in the aspartate polymer, but nevertheless the positive value of b_0 may mean that the helix has a left-hand screw sense.

We have measured the rate of replacement of NH by ND in a solution of poly-β-benzyl-L-aspartate in methylene chloride containing 1 per cent (v/v) of O-deuterated acetic acid. The rate is many times greater than that for poly-γ-benzyl-L-glutamate (of a similar reduced viscosity in dichloracetic acid) under similar conditions, leading to the conclusion that the helical configuration of the aspartate polymer is less stable than that of the glutamate.

Further evidence of this comparative instability is provided by the behaviour of solid films on heat treatment. Oriented films of the α-form of poly-γ-benzyl-L-glutamate are stable to heating *in vacuo* at about 170° C. for some hours, becoming more crystalline[5]. Similar treatment of the aspartate polymer, however, produces a specimen in which the X-ray diffraction pattern is replaced by a completely new one. This new form (which we propose to call the ω-form) has a tetragonal (not hexagonal) unit-cell base, and a meridian reflexion at 1·3 A., but none at 1·5 A. The five layer lines observed correspond at least approximately to orders of a strong layer line at 5·2 A. The infra-red dichroism of the peptide bands is not appreciably altered by the heat treatment, so that the new form is probably produced with little change in the atomic positions within one residue. A fold described by Bragg, Kendrew and Perutz[6] as 4_{13}, topologically similar to the α-helix (being formed by the same 13-membered hydrogen-bonded rings) but with amide groups not quite planar, may be found to fit the new X-ray pattern. This fold has a residue repeat of about 1·3 A., and having a four-fold screw axis would be expected to pack tetragonally. The measured density of the heated polymer is 1·31 gm./c.c., in satisfactory agreement with the crystallographic density 1·36 for a tetragonal unit cell with $a_0 = b_0 = 13 \cdot 85$, $c_0 = 5 \cdot 2$ A. containing four residues.

The reason for the instability of the α-helix in the aspartate polymer is probably connected with interaction between the peptide groups and the side-chains. In the new form the ester C=O band is at 1,727 cm.$^{-1}$, while in the α-helix form it has the usual frequency 1,737 cm.$^{-1}$; it has also acquired appreciable parallel dichroism. The peptide C=O band, on the other hand, is at 1,664 cm.$^{-1}$ and 1,675 cm.$^{-1}$ in the α-helix and new forms, respectively. These peptide C=O frequencies are higher than any so far reported for polypeptides made from a single optical isomer. When the heat-treated polymer is dissolved in chloroform, it is found that films cast from the solution have infra-red spectra identical with those of the unheated films.

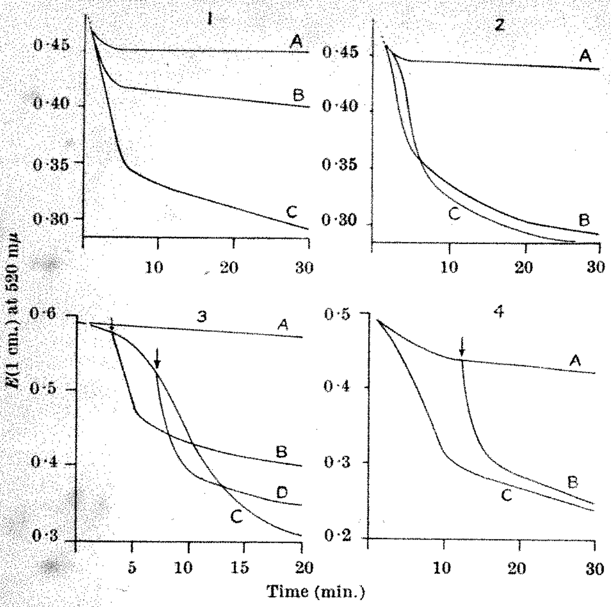
Effects of 2 : 4-Dinitrophenol and Other Agents on the Swelling of Isolated Mitochondria

WE have offered evidence[1] that, under various conditions, the swelling of isolated rat-liver mitochondria is dependent on the presence of oxidizable subtrates. For example, if the particles are stored for one day in 0·44 *M* sucrose at 0° C. ('aged'), phosphate or thyroxine no longer causes them to swell unless certain oxidizable subtrates, for example, β-hydroxybutyrate, are added as well. Reasons were given for supposing that, in many circumstances, swelling is dependent on mitochondrial respiration. We suggested that, in view of the stabilizing action of 0·1 m*M* 2 : 4-dinitrophenol[2], any effect of respiration on swelling may be exerted through coupled phosphorylation (see also ref. 3); however, after a more extensive



Figs. 1–4. Swelling of mitochondria at 20° C. All cells contained 10 m*M* phosphate, 25 m*M* *tris* chloride buffer *p*H 7·5 and 0·3 *M* sucrose. Fig. 1. 2 : 4-Dinitrophenol added initially; fresh mitochondria. Curve *A*, 0·1 m*M* dinitrophenol; curve *B*, 0·02 m*M* dinitrophenol; curve *C*, control. Fig. 2. As for Fig. 1, but with 2 m*M* DL-β-hydroxybutyrate. Fig. 3. 0·1 m*M* dinitrophenol added (arrows) during swelling in the presence of 1 m*M* D-β-hydroxybutyrate; aged mitochondria. Curves when dinitrophenol added (*A*) at zero time; (*B*) at 3 min.; (*D*) at 7 min.; (*C*) control. Fig. 4. Inhibition with oligomycin (0·4 μgm./ml.) and release (arrow) by 0·01 m*M* dinitrophenol; 2 m*M* DL-β-hydroxybutyrate present; fresh mitochondria. Curve *A*, oligomycin; curve *B*, oligomycin followed by dinitrophenol; curve *C*, control

study of the effects of uncoupling agents we think that this is unlikely to be so. Thus, lower concentrations of 2 : 4-dinitrophenol, and dicoumarol, will, under some conditions, accelerate the swelling induced by phosphate, and even 0·1 m*M* dinitrophenol will increase the rate of swelling if it is added after the mitochondria have been previously incubated in the presence of phosphate.

Twice-washed mitochondria were prepared and studied under our routine conditions[1]. With fresh mitochondria, in the absence of added substrate, 0·1 and 0·02 m*M* dinitrophenol, present initially, inhibited swelling induced by 10 m*M* phosphate with a lag period of 2–4 min. (Fig. 1). Here the lower concentration of dinitrophenol was scarcely less effective than the higher, but in the presence of 2 m*M* DL-β-hydroxybutyrate and phosphate (Fig. 2) 0·02 m*M* dinitrophenol slightly accelerated the swelling, whereas 0·1 m*M* was still strongly inhibitory. With aged mitochondria under the same conditions, 0·02 m*M* dinitrophenol slowed the swelling considerably. However, after they had been pre-incubated with β-hydroxybutyrate for 8 min. at 20° C., subsequent addition of phosphate together with 0·02 m*M* dinitrophenol produced a swelling response similar to that obtained with fresh mitochondria, that is, swelling with phosphate and dinitrophenol was more rapid than that with phosphate alone. Consistent with this finding, addition of even 0·1 m*M* dinitrophenol to fresh or aged particles in the process of swelling induced by phosphate with β-hydroxybutyrate caused acceleration (Fig. 3).

With fresh mitochondria, when phosphate was replaced by thyroxine (7 μ*M*), 0·1 m*M* dinitrophenol completely arrested swelling when present from the start, but when it was added later swelling was accelerated. This occurred in the presence of β-hydroxybutyrate, with fresh and aged particles. Dicoumarol (5–10 μ*M*) behaved similarly to dinitrophenol in this respect. With fresh particles 10 μ*M* dicoumarol had an effect on phosphate-induced swelling similar to that of 0·02 m*M* dinitrophenol (Fig. 2), except that the initial fall was more rapid and the extent of swelling less. With aged mitochondria, in the presence of β-hydroxybutyrate, swelling induced by phosphate was completely stopped by dicoumarol added initially; later addition of dicoumarol caused acceleration, as was the case with dinitrophenol.

These acceleratory effects of dinitrophenol and dicoumarol could not be reproduced by delayed additions of other known inhibitors[4] of swelling, namely, manganese chloride, ethylenediamine tetraacetate, cyanide or adenosine diphosphate, or by low concentrations of antimycin *A* or amytal[1,5]. Among other uncouplers tested, mepacrine[6] (1 m*M*) was relatively ineffective in preventing the phosphate-induced swelling of fresh mitochondria, but was strongly inhibitory with aged particles; lower concentrations down to 0·05 m*M* failed to produce acceleration. In contrast to mepacrine, aureomycin (0·07 m*M*) completely stopped the swelling of fresh mitochondria—indeed, the optical density rose above its initial value—but was only partially effective with aged mitochondria.

Oligomycin inhibits respiration, and this inhibition is reversed by dinitrophenol, which suggests that this antibiotic acts on the phosphorylation system rather than on the respiratory chain[7]. With fresh mitochondria in the presence of β-hydroxybutyrate, oligomycin (0·4 μgm./ml.) strongly inhibited the swelling produced by phosphate; 0·01 m*M* dinitrophenol (Fig. 4), or 3 μ*M* dicoumarol, abolished this effect. With aged particles oligomycin no longer inhibited swelling. It also failed to affect swelling induced by thyroxine, even with fresh mitochondria.

The acceleratory effects of dinitrophenol and dicoumarol, and particularly the reversal by dinitrophenol of the inhibition of swelling by oligomycin, indicate that swelling may occur when phosphorylation is uncoupled, and suggest that the effect of respiration on swelling is not exerted through the phosphorylation process. The inhibition of swelling by high concentrations of dinitrophenol and other uncoupling agents might be due to actions on the mitochondrial structure or to a deleterious effect on co-factors of respiration. It may be noted that aureomycin in low concentrations inhibits respiration as well as phosphorylation[8].

We wish to thank Dr. B. C. Pressman for a generous gift of oligomycin, and Mr. Colin Taylor for expert technical assistance.

Spectrophotometric Investigation on the Orcein Derivative of Elastin

IRREVERSIBILITY of the reaction between orcein and elastin[1] and the strength of the bond, which varies with different dyestuffs and proteins, supports the hypothesis of purely chemical bond rather than that of a hydrogen bond or an adsorption complex.

The existence of a chemical bond may be demonstrated spectrophotometrically, employing the principle of conjugation bathochromy: it is known that conjugation of two chromophore groups produces a shift of the absorption maximum towards longer wavelengths.

Orcein and its reaction product with elastin (orceinelastin) have been spectrophotometrically investigated. Orcein was dissolved in a *p*H 8·9 buffer. Purified orceinelastin, obtained by complete removal of the free colour from the reacted elastin, was brought into solution by digestion with elastase (the elastolytic enzyme of Balò and Banga) at *p*H 8·9.

The absorption spectrum of the coloured digestion products of orceinelastin was found to be the same as orcein except for a bathochromic shift of the absorption maximum from 574 to 589 mμ. Since a bathochromic shift is a property of the conjugation link only, the existence of a sharing bond between orcein and elastin is indicated.

By comparing extinction values of pure orcein with digested orceinelastin ones, the stoichiometry of the compound was found to be 1·265 gm. ($2 \cdot 53 \times 10^3$ moles) orcein/100 gm. elastin. This quantity was found not to depend, within large limits, on the reaction temperature and orcein concentration. This provides further evidence that there is a chemical bond in orceinelastin. The only value reported in the literature is by Weiss[2] (no methods specified) of 2×10^2 moles/100 gm. elastin.

Ultra-violet Fluorescence of Quinine Sulphate for Detection of Phosphate Ester Spots on Paper

A WIDE variety of phosphate esters have great importance as intermediates in biological reactions. Development of adequate procedures for the chromatography and detection of these phosphate esters has, in many respects, lagged behind. With the exception of the method of Runeckles and Krotkov[1], which was developed as a modification of the procedure of Wade and Morgan[2], the detection of phosphate esters on paper chromatograms has been very laborious and relatively insensitive. Most of the molybdate procedures, in addition to requiring many manipulations, have the disadvantage of employing perchloric acid, which weakens the paper and causes some charring during heating.

This communication reports a simple dip procedure by which phosphate spots containing as little as 0·007 μmole of phosphorus can be detected. The phosphate spots are located by immersing the developed and dried paper in a solution of 0·5 per cent quinine sulphate·$2H_2O$ in absolute ethanol. After drying the paper at room temperature for a few minutes, the phosphate spots can be detected by examining the paper under ultra-violet light in a darkened room. The spots show up as light areas against an intense grey-blue fluorescent background.

The best results were obtained with a low-pressure mercury source filtered to exclude visible light and producing predominantly ultra-violet radiation in the 2537-A. region. A long-wave lamp with ultra-violet radiation in the 3600-A. region and also filtered to exclude visible light was, in general, found to be only a little less satisfactory than the 2537-A. source.

In only one case was a qualitative difference noted between the two ultra-violet sources; that was with adenosine triphosphate, guanosine triphosphate and uridine triphosphate on a paper developed with a butanol, acetic acid and water solvent. With the 3600 A. source all three compounds appeared as light spots against a fluorescent background, but with the 2537 A. source, the first two appeared as dark blue spots while the uridine triphosphate appeared as a light spot against the fluorescent background.

The quinine sulphate dip, in addition to its ease of use, offers the great advantage of employing an alcohol-soluble and apparently non-reacting spot-detecting compound. After marking the spots under ultra-violet light as rapidly as possible, one can wash the bulk of the quinine sulphate off the paper with absolute ethanol, thus leaving the phosphate ester spots unmoved and free for elution and further determinations. The spots may also be left on the paper, following the alcohol wash, for study by other spot-detection procedures such as specific ketose reactions.

The sensitivity of this dip procedure for detecting various phosphate compounds which were developed on paper chromatograms is shown in Table 1.

Table 1. DETECTION OF COMPOUNDS CONTAINING PHOSPHORUS WITH QUININE SULPHATE ON DEVELOPED PAPER CHROMATOGRAMS

Substance tested	Smallest amount of test material showing a strong spot (μgm. free acid)
Orthophosphate	0·7

Quinine sulphate is not selective for phosphate esters, but other organic compounds which might be present in chromatograms of this type, such as free sugars and amino-acids, must be present in relatively high concentrations before they are detected under ultra-violet light. Free sugars are not detected in amounts smaller than 40 μgm. per spot and only a few of the amino-acids tested could be detected in amounts as small as 15 μgm. per spot. A confirmatory ninhydrin dip or spray to detect any amino-acids which might be present can be run on the same paper following the quinine sulphate dip and subsequent ultra-violet examination. The quinine sulphate left on the paper does not interfere with the ninhydrin test. Purines, pyrimidines and nucleosides show up strongly. This was expected, since fluorescent procedures such as that of Pfennig[3] have been used to enhance the natural quenching of these compounds under ultra-violet light.

The paper ionophoresis and chromatography techniques of Runeckles and Krotkov[1] are ideally suited for this dip procedure since volatile buffers and solvents are used. The presence of inorganic salts in the developing solvents for the papers causes rather severe interference with spot detection. Interference from compounds such as trichloracetic acid, however, can be minimized by washing the papers with absolute ethanol or other suitable solvents prior to the quinine sulphate dip.

The dip procedure has worked well with a variety of papers including Whatman No. 1 and Schleicher and Schuell No. 507. In most cases, prior washing of the paper has been found beneficial. With some papers, however, washing has not always been necessary if the solvent front is sufficiently removed from the spots under study.

Isolation of Kojibiose from Honey

Previously, we reported[1] that fifteen honey samples produced mainly in the Tohoku region of Japan were analysed, and sugar components of one kind of honey (*Lespedeza bicolor*) were fractionated by chromatography, using a carbon : 'Celite' column, and the sugars in each fraction were estimated. Glucose, fructose, sucrose, maltose, melezitose, eight di- or tri-saccharides and nine higher oligosaccharides were detected by paper chromatography, and fifteen spots of them contained ketose.

On the other hand, it has been reported that Goldschmidt *et al.*[2] detected *iso*maltose in honey by paper chromatography and White *et al.*[3] isolated nigerose from honey.

We now report the isolation of kojibiose. Honey (*Lespedeza bicolor*, 300 gm.) was fractionated with a carbon : 'Celite' column (550 mm. × 125 mm.) using water (22 l.), and ethanol, 2·5 per cent (22 l.), 5 per cent (14 l.), 10 per cent (18 l.), 15 per cent (18 l.), 20 per cent (14 l.), 25 per cent (12 l.) and 30 per cent (30 l.) as successive elution solvents. Kojibiose was detected in 2·5–5 per cent ethanol effluent by paper chromatography. The effluent portions containing kojibiose from three columns (900 gm. honey) were combined (16·5 gm. sugar mixture). These portions were contaminated with a considerable amount of *iso*maltose, two oligosaccharides containing ketose, glucose, fructose, sucrose and a trace of leucrose.

The sugar mixture was then rechromatographed on a carbon : 'Celite' column (530 mm. × 80 mm.) using the gradient elution method with 0–3·0 per cent aqueous ethanol containing borate buffer (*p*H 10·0)[4]. Substantially perfect separation of kojibiose from other sugars was achieved. The water fractions contained monosaccharides, and the 0·5–1·5 per cent ethanol fractions contained *iso*maltose and several sugars containing ketose. Kojibiose appeared in the 2·0–3·0 per cent ethanol fractions.

By the removal of borate from the sugar complex by repeated distillation with methanol, 1·3 gm. of chromatographically pure kojibiose was obtained. Since direct crystallization of the sugar acetylated in the usual way was not successful, the benzene solution of the crude acetate was poured on a column (300 mm. × 40 mm.) of 'Magnesol' : 'Celite' (5 : 1) and developed with 1,000 ml. of benzene/*t*-butanol (100 : 1 by vol.). A zone appeared at 165–215 mm. from the top of the column, which, by means of potassium permanganate streak indicator, was sectioned from the column and eluted with acetone. Removal of the solvent left 0·5 gm. of syrup, from which 208 mgm. of fine prisms were obtained upon crystallization from ethanol. It had m.p. 117–118° C., $[\alpha]_D$ + 113·8° (*c.* 1·2 in chloroform).

The upper portion (10–165 mm.) of the column was eluted with acetone, and removal of the solvent left 0·7 gm. of syrup. This syrup was rechromatographed on the 'Magnesol' : 'Celite' column. From the zone at the bottom of the column, 0·1 gm. of syrup was obtained which upon crystallization from ethanol gave 11 mgm. of fine prisms. It had an m.p. of 166° C.

Neither acetate showed depression of melting point on admixture with α- and β-kojibiose octa-acetates (166° and 117° C.) synthesized chemically by Matsuda[5].

We wish to acknowledge our indebtedness to Mr. K. Matsuda for his advice.

Purification of Bacterial Neuraminidase (Receptor-destroying Enzyme)

Neuraminidase is the name now given to an enzyme the action of which is the hydrolytic cleavage of the glycosidic bond joining the keto group of N-acetylneuraminic acid to D-galactose or D-galactosamine[1]. The enzyme was discovered in 1946 when Burnet, McCrea and Stone[2] found that filtrates of *V. cholerae* rendered human cells inagglutinable by influenza viruses. The factor responsible for this action was called the receptor-destroying enzyme by Burnet and Stone, who obtained some purification of the enzyme present in *V. cholerae* (strain 4 *Z*) filtrates by adsorption to and elution from red cells[3]. This technique was later incorporated into a three-step procedure for the partial purification of the enzyme[4]. Crude or semi-purified receptor-destroying enzyme has since been used as a standard reagent in influenza virus studies: further work in this field, together with increasing interest in the biological and chemical properties of compounds containing

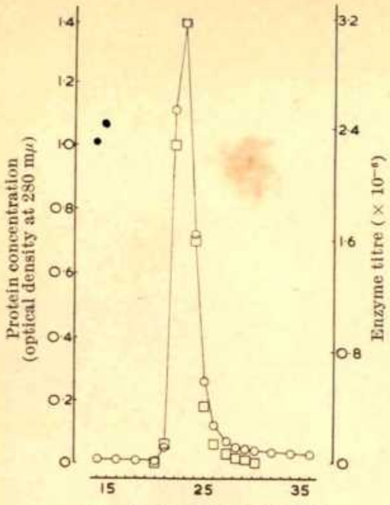

Fig. 1. Purification of neuraminidase by chromatography on hydroxyapatite. Elution pattern using a concentration gradient of phosphate buffer, pH 6·8. ○—○, Protein concentration; □—□, enzyme titre

N-acetylneuraminic acid, have emphasized the need for the pure enzyme.

Improved yields of enzyme have recently been obtained using a medium composed of bovine colostrum dialysate to which were added peptone and glycerol[5]. Following the growth of *V. cholerae* in such medium and subsequent heating to kill the organisms, filtration yields a crude extract from which it has now been possible to purify and crystallize the enzyme.

Enzyme estimations were carried out by the biological method previously described[6]. Protein concentrations were assessed by tyrosine estimations[7], by absorption at 280 mμ or by refractometry.

The purification process is briefly as follows.

(1) Cold methanol is added to 36 litres of crude extract (pH 5) to give a final concentration of 60 per cent. The precipitate which forms is suspended in and dialysed against water and a clear extract is obtained by centrifugation.

(2) Neuraminidase in the extract (sodium chloride, 0·8 per cent; calcium chloride, 0·1 per cent; pH 8·5, 2° C.) is adsorbed on to fresh, washed, packed human red cells and eluted from the cells in the presence of ethylenediamine tetraacetate (0·01 M, pH 7, 20° C.).

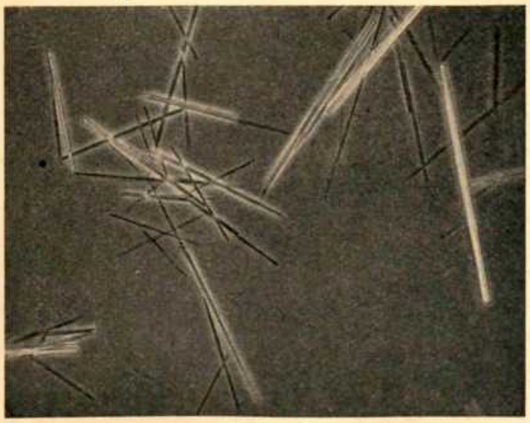

Fig. 2. Crystalline neuraminidase (phase contrast, × 300). Photograph by Mr. E. Matthaei

(3) An equal volume of saturated ammonium sulphate solution (pH 7, 2° C.) is added to the clarified eluate (2° C.). The precipitate which forms is dissolved in and dialysed against buffered saline (0·1 M sodium chloride, 0·001 M phosphate, pH 6·8).

(4) The enzyme is adsorbed on to a column of hydroxylapatite[8] and the column developed with a gradient of phosphate-buffered saline, pH 6·8 (phosphate concentration 0·001–0·25 M), the eluate being collected in a fraction collector. The enzyme elutes as a single peak, which, on re-chromatography, yields typically a result like that shown in Fig. 1. In the experiment shown, tubes 22, 23 and 24 were pooled and dialysed against water.

(5) The dialysed solution is concentrated to about 2 ml., adjusted to about pH 4·3 and then gently shaken at 2° C. for 2–3 days, when crystals appeared (Fig. 2).

The crystalline enzyme has an enzymic activity of about $8 \cdot 6 \times 10^6$ units/mgm. of protein (protein estimated by refractometry). This represents a purification of approximately 1,000-fold. In three experiments the overall yield of crystalline enzyme was 33, 30 and 52 per cent.

Details of the purification process and properties of the enzyme will be published elsewhere.

PATHOLOGY

Human Muscular Dystrophy as an Aberration of the Connective Tissue

The pathological changes in the muscle in human muscular dystrophy have been well characterized. They consist of great diversity of muscle fibre size, increase in number of sarcolemmal nuclei (which may take the form of chains situated centrally in the fibre), and atrophy of the fibres. Although it has been said[1] that phagocytosis of degenerating fibres is rare, we have found evidence in a number of cases of what appears to be invasion and destruction of muscle fibres by elements of connective tissue.

Muscular dystrophy is also characterized by a proliferation of the connective tissue with the accumulation of varying amounts of fat.

It has been shown by histochemical methods[2] that this connective tissue contains appreciable 5-nucleotidase activity, whereas very little of this activity is present in the connective tissue of normal human muscle. Since this enzyme dephosphorylates adenosine monophosphate, we investigated the ability of the connective tissue to dephosphorylate various high-energy phosphates derived from adenosine monophosphate and other esters and also some other phosphate compounds of physiological importance.

Fig. 6. Substrate: Adenosine triphosphate. Dystrophic muscle, pH 9. Intense reaction by proliferating connective tissue elements. The reactions given in 5 and 6 are by a heat-stable adenosine triphosphatase which appears to be different from the conventional adenosine triphosphatase of the muscle fibre

Fig. 7. Substrate: Triphosphopyridine nucleotide. Control muscle, pH 9. All elements negative

Fig. 8. Substrate: Triphosphopyridine nucleotide. Dystrophic muscle, pH 9. Considerable reaction by elements of proliferating connective tissue and muscle nuclei

Fig. 9. Substrate: Thiamine pyrophosphate. Control muscle, pH 7·5. All elements negative

Fig. 10. Substrate: Thiamine pyrophosphate. Dystrophic muscle pH 7·5. Spectacular dephosphorylation of proliferating connective tissue and moderate reaction by muscle fibres

They included adenosine di- and tri-phosphates, uridine, guanosine, cytidine, inosine and acetyl phosphates and creatine phosphate. Phosphorylated co-enzymes such as riboflavin-5-phosphate, thiamine pyrophosphate, pyridoxal phosphate, di- and triphosphopyridine nucleotides and glycolytic intermediates such as glucose-1- and glucose-6-phosphates, fructose-1- and 6-phosphates, hexose diphosphate and phosphoglyceraldehyde. The histochemical reactions for all these compounds were compared with that for β-glycerophosphate. Our studies in 10 cases of muscular dystrophy showed that in every case, with the exception of creatine phosphate, all the high-energy phosphate compounds were actively dephosphorylated by the connective tissue and by a number of the muscle fibres. On the other hand, the intermediate glycolytic compounds were not hydrolysed. Of the co-enzymes, riboflavin-5-phosphate and pyridoxal phosphate were not affected, but in two out of the ten cases of dystrophy there was a spectacular dephosphorylation of thiamine pyrophosphate. Probably the most interesting result was the dephosphorylation of diphosphopyridine nucleotide and to a lesser extent triphosphopyridine nucleotide by the connective tissue in every case examined.

The presence of enzymes destructive of compounds vital to muscle metabolism in connective tissue enveloping the muscle fibres must have some significance in muscular dystrophy.

There are three possible interpretations of these observations:

(1) Although these metabolically important phosphate compounds are synthesized by muscle there may be some leakage in normal metabolism much as vitamin A leaks away from the retina in the retinene cycle. Replacement of this leakage by transport from the vascular and lymphatic system if there is inadequate synthesis by the muscle itself would be prevented by connective tissue containing the appropriate phosphorolytic enzymes.

(2) The fundamental defect may still be in the membrane of the muscle fibres, and the diffusion of phosphate esters out into the surrounding milieu may result in adaptive synthesis of enzymes to hydrolyse them in the connective tissue.

(3) That the excessive production of these hydrolytic enzymes by the connective tissue leads to their diffusion to and adsorption on to and eventual penetration of the muscle fibre membrane resulting in complete block of the normal metabolism of the fibres.

Of these possibilities (2) is currently under investigation in this laboratory, and of (1) and (3) the latter appears to be more in keeping with current views of muscle metabolism although the penetration of the sarcolemma by hydrolytic enzymes has yet to be established. However, it does not seem improbable that the accumulation of such a range of phosphatases at this site might break down both its structural integrity and its selective permeability.

These results suggest that the fundamental defect in progressive muscular dystrophy may be not in the muscle fibre but in the connective tissue which supports it.

This work is supported by a grant from the Muscular Dystrophy Associations of America Inc. and with equipment provided by the National Foundation for Muscular Dystrophy, New York.

Chemical Changes in Human Bronchial Epithelium and their Relation to Bronchial Cancer

A RECENT histological study[1] of the changes that occur in human bronchial epithelium has confirmed in part earlier American findings[2] and shown that considerable proliferation may occur in the cells of the basal layer without any other histological abnormality. As it seemed possible that some of these changes might be related to the development of bronchial cancer, a histochemical investigation has been begun. Since this work was not concerned with the distribution of free lipids, formalin-fixed tissue embedded in paraffin was used. The most striking result has been the very marked increase in the content or availability of lipid, probably bound phospholipid[3], as shown by colouring with sudan black and staining by the acid hæmatein method[4]. This effect was strongest in the nuclei of the basal cells and was particularly well seen in the condition known as basal cell hyperplasia. In contrast, scarcely any lipid could be demonstrated in the cells of foci of established squamous metaplasia.

Since basal cell hyperplasia and other proliferative changes are common in smokers who exceed 40 cigarettes a day, it seemed worth-while to see if similar histochemical disorders occurred in histologically normal areas of bronchial epithelium in such persons. By these methods an increased lipid content has now been demonstrated in the basal cells, particularly in the nuclei, of otherwise normal bronchial epithelium from such smokers; in chemically normal epithelium from non-smokers only the nucleoli in the basal cells are stained.

Sections were also treated with an aqueous (hydrotropic) solution of 3,4-benzpyrene, and the distribution of this fluorescent carcinogen was followed by fluorescence microscopy. Those cells which gave a positive reaction with the acid hæmatein method also showed selective absorption and concentration of benzpyrene, especially into the nuclei.

If these observations on fixed cells can be related to events in the living epithelium, they would suggest the possibility that bronchial cancer is produced in two main stages. In the first stage, damage to areas of epithelium, possibly by cigarette smoking, might alter them in such a way as to increase their affinity for lipid-soluble substances, leading to preferential absorption of carcinogenic hydrocarbons in the second stage. These events need not necessarily occur in every focus of proliferation, and the development of bronchial cancer might also be affected by local differences in the concentration of carcinogens which accumulate in the vicinity of the foci. The circumstances influencing the local concentration of carcinogens are probably complex and include such factors as stagnation of mucus and loss of cilia.

We acknowledge, with much gratitude, the generous help given us by Dr. E. Nassau and Mr. R. F. Cummings, of Harefield Hospital, Middlesex. We are also indebted to the Imperial Cancer Research Fund, which has financed these investigations.

BIOLOGY

Selective Staining of Visceral Efferents in the Rat Brain Stem by a Modified Koelle Technique

THE histochemical technique for cholinesterases introduced by Koelle and Friedenwald[1] has been used in numerous studies of nervous tissue. Much of this work has been concerned primarily either with the histochemistry of the method or with the cytological distribution of enzyme revealed. This method has, we feel, also great potentialities in the field of neuro-anatomy—as a means of selectively staining particular groups of neurones which cannot otherwise be distinguished by more conventional methods. Some attempts along these lines have been made in studies of peripheral innervation[2,3], but it is in studies of the central nervous system that there is particular need for a selective staining method. This communication is therefore concerned not so much with enumerating our detailed findings in this preliminary investigation as with emphasizing the potential value of this technique in solving many neurological problems which have so far resisted attack by more conventional methods.

The sensitivity of the Koelle technique can be controlled by varying the *p*H of the incubation medium and the time of incubation. At an acid *p*H the method is highly selective for sites of high enzyme activity. This fact was made use of by Snell and Garrett[4] in their study of the cholinergic innervation to the rat salivary glands—the secretor-motor fibres, both pre- and post-ganglionic[3], being selectively shown up when a sufficiently acid incubation medium was used. This work suggested that it might be possible with some such technique to follow the salivatory pathway back to the salivatory nuclei in the hind

Weakly stained

Branchiomotor efferents of V and VII
Ponto-cerebellar fibres (brachium pontis)

brain, the exact site of which was uncertain. In the rat, this possibility appears to have been realized.

The precise procedure which finally proved to give the best results for our immediate purpose was, very briefly, as follows. The relevant region of the hind brain was dissected out, fixed in cold 10 per cent formol-saline and then well washed in water. Serial transverse sections were cut at 40μ on the freezing microtome and the individual sections treated by the Koelle technique with a *p*H of 4·8–4·9 and an incubation time of about 3 hr. The sections were then mounted serially on glass slides, allowed to dry and afterwards mounted in balsam via absolute alcohol and xylene. These sections were not counterstained in any way: instead they were compared with several companion series of wax sections which had been stained in other ways (Bodian, modified Weigert, cresyl violet).

The brain-stem structures which showed significant staining by this technique are listed in Tables 1 and 2. The patterns of staining seen in and around individual cells were of three main types. Staining confined to the cell bodies and their processes was seen in the caudo-ventral portion of the sensory nucleus of V, in the dorsal motor nucleus of X and in the nucleus of the locus coeruleus. At most of the other sites listed in Table 1 there was significant staining also outside the cells which was most marked in the salivatory nucleus and in the nucleus ambiguus. The third type, in which staining was confined to small discrete areas of the cell surface, was less frequently seen and was most obvious in some of the giant cells of the reticular formation. One is tempted to suggest that each of these three types of pattern represents a different type of synaptic junction: the first, cholinergic neurones receiving mainly non-cholinergic presynaptic terminations; the second, cholinergic neurones which either receive significant cholinergic innervation from elsewhere in the central nervous system or possess recurrent collaterals; and the third, non-cholinergic neurones which receive some cholinergic innervation.

The difference in the intracellular staining of the various types of motor cells and of their processes was very striking. In general, visceral efferents were strongly stained, branchial efferents moderately and somatic efferents only weakly stained. These results imply that the enzyme activity possessed by these three classes of cholinergic neurons must be markedly different, though why this should be so is not immediately obvious. Whatever the underlying reasons, however, the heavy differential staining of the salivatory efferent fibres made it possible to establish their cells of origin with reasonable certainty. It has been generally supposed that there are two salivatory nuclei, an 'inferior' and a 'superior', both situated in the lateral reticular formation. In our material, however, the fibres of the nervus intermedius could be traced via two roots to a dorso-medially placed salivatory nucleus, in series with the Edinger-Westphal nucleus and the dorsal motor nucleus of X. The nucleus is subdivided by the anterior genu of VII into a larger lateral and a small medial part. These two parts of the salivatory nucleus are connected across the top of the genu by strongly stained fibres but not by cells. Some fibres, presumably from the medial part, cross the midline. There is no inferior nucleus in the region between the salivatory nucleus and the dorsal motor nucleus of X, but a fibre bundle leaves the more ventral root of the nervus intermedius to join the efferent outflow of IX. No salivatory cells can be seen in the traditional site for the superior nucleus in the lateral reticular formation. This more dorsal position for the salivatory nucleus does not conflict with most of the available physiological evidence. It is strikingly consistent with the result of stimulation experiments on the monkey[5] and on the cat[6]: so it is probable that our findings in the rat hold for other mammals.

The observations mentioned here, particularly those relevant to possible central salivatory pathways, will be described and discussed in greater detail elsewhere.

Fate of Spermatozoa penetrating into the Tissues of the Fallopian Tube

IN a re-investigation of previous work[1], spermatozoa were recently observed in the mucous membrane of the Fallopian tubes of greater horseshoe bats[2], and a similar occurrence was later found in common pipistrelle bats, rats, stoats, one rabbit, and one hedgehog[3]. There was some evidence of a response of the nuclei of the tubal cells to the spermatozoa[3]. In view of these observations, we have examined the Fallopian tubes of mice mated to radioactive males known to be ejaculating large numbers of spermatozoa labelled in deoxyribonucleic acid with adenine-8-^{14}C[4]. By using autoradiography, the labelled sperm chromatin can be identified even though the spermatozoa are no longer recognizable morphologically[5]. The Fallopian tubes were accordingly examined autoradiographically. Particular attention was paid to the mucosa and sub-mucosa, to find out if spermatozoon deoxyribonucleic acid was incorporated into the nuclei or formed nuclei in the female tract.

The Fallopian tubes of five mice were examined in detail. Four of them had been autopsied 12 hr. after mating, the fifth 24 hr. after mating. Many labelled spermatozoa were found between the nuclei of the mucosal cells, which is to be expected from previous work[1-3], though the displacement of some of these spermatozoa during sectioning[6] is possible. Three autoradiographs in the animal killed 24 hr. after mating were associated with sperm heads that appeared swollen and possibly disintegrating. Several thousand nuclei in the mucosa and sub-mucosa were examined, and none was found to give a definite autoradiograph.

Our evidence indicates that spermatozoa do not form nuclei in the mucosa or contribute detectable amounts of deoxyribonucleic acid to mucosal cell nuclei in the Fallopian tubes. Though the chance of detecting nuclear autoradiographs depends on the percentage of spermatozoa that are labelled, the intensity of labelling[4], etc., sufficient numbers of nuclei were examined to exclude the possibility of large-scale participation of male chromatin in them. Our results do not preclude the possibility of the entry of some components of spermatozoa into nuclei, for the intensity of labelling is more favourable to the detection of whole spermatozoon heads than to parts of them. While not ruling out the possibility of xenia, telegony or other effects of the excess spermatozoa in the female tract (see refs. 1, 7), our present results support previous findings[8], which gave no evidence to support theories of these phenomena based on the incorporation of spermatozoa into tubal or uterine cells.

Electron Microscope Observations on the Neurohypophysis of the Ferret

We have observed, while studying the neurohypophysis of the ferret using the electron microscope, that the mitochondria in the neurosecretory fibres are of unusual form and that this form can be modified by experiment.

The features we have observed are evident in specimens fixed either by buffered osmium tetroxide or by buffered potassium permanganate, though they are more obvious after the latter fixative.

The mitochondria are irregular in form, and in many instances one or more deep invaginations are present (Fig. 1). In permanganate-fixed preparations the area contained within an invagination is strikingly less electron-dense than the rest of the cytoplasm, and we believe that this may indicate a concentration of some specific substance produced by, or involved in, the activity of the mitochondrion.

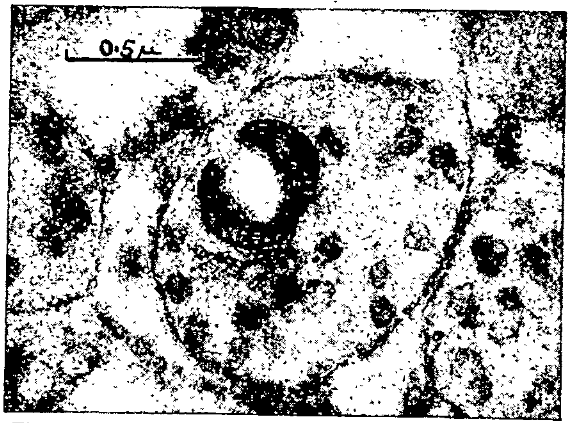

Fig. 1. A nerve fibre in the neurohypophysis of a ferret. It contains neurosecretory vesicles and a single invaginated mitochondrion. The area of the invagination is less electron-dense than the surrounding cytoplasm. The tissue was fixed in buffered potassium permanganate

The pituitary stalks of some animals were severed and the neurohypophysis was examined at various intervals after the operation. Up to four days after stalk section the only apparent effects of the operation were changes in the form of the mitochondria. These continued to be irregular; but the invaginations were less marked and were very rarely associated with any area of electron density different from the rest of the cytoplasm. We interpret this as evidence of some alteration in the activity of the mitochondria following section of the stalk.

A parallel series of histochemical studies was carried out, using the performic-acid – Alcian blue technique[1] which stains selectively cystine-containing material. Some shrinkage of the neurohypophysis followed section of the stalk, but large amounts of Alcian-blue-positive material persisted for at least four days following the operation. It is interesting to note that the electron microscope showed that neurosecretory vesicles were also present during the post-operative period.

It is widely held that[2,3] the neurosecretory material in the neurohypophysis is elaborated in the hypothalamus and that it then passes down axons in the pituitary stalk. It is interesting to find that such material is still present in the distal part of the neurohypophysis four days after section of the axons.

The Nematodes *Ostertagia lyrata* Sjöberg, 1926, and *Trichostrongylus longispicularis* Gordon, 1933, in British Cattle

A list of the gastro-intestinal nematodes of British cattle, published by Morgan and Soulsby[1], included two species of *Ostertagia* (*O. ostertagi* and *O. circumcincta*) and three species of *Trichostrongylus* (*T. axei*, *T. vitrinus* and *T. colubriformis*). Observations at Weybridge indicate that an additional species of each of these two genera, namely, *O. lyrata* and *T. longispicularis*, should be added to this list.

These two species were present in material collected during the routine post-mortem examination of bovines which were suffering from parasitic gastroenteritis, and which had been sent to the Laboratory from farms in the south-east of England. *O. lyrata* together with *O. ostertagi* was recovered from the abomasum, and *T. longispicularis* together with

Cooperia spp. and *Nematodirus* spp., was recovered from the small intestine.

O. lyrata can be differentiated readily from *O. ostertagi*, and from *O. circumcincta*, which also occurs in the abomasum, as the copulatory bursa and spicules are characteristic for each species[2]. Differentiation of the *Trichostrongylus* species is more difficult, *T. longispicularis* and *T. colubriformis* being very much alike. In both species the spicules are the same general shape, except at the tips, but those of *T. longispicularis* are slightly longer than those of *T. colubriformis*. The gubernaculum, however, is quite distinctive for each species and provides an additional means of differentiating the two.

O. lyrata has been recorded from cattle, sheep and deer. It is known to occur in Europe, North America and Africa. According to Becklund[3] it is a fairly common cattle parasite in Georgia, U.S.A.

T. longispicularis has been recorded from both sheep and cattle in Australia and North America. It is said to be fairly common in cattle in certain parts of Australia[4].

There is no experimental evidence relating to the pathogenicity of either *O. lyrata* or *T. longispicularis*. It seems reasonable to suppose, however, that heavy infestations will have harmful effects on the host similar to those produced by other species of *Ostertagia* and *Trichostrongylus*.

Food Selection by Silkworm Larvæ

THIS communication reports the presence of three stimulants in mulberry leaves which induce their preferential selection as food by silkworm larvæ. The first, which attracts the larvæ on to these leaves, has been identified as β,γ-hexenol or α,β-hexenal by T. Watanabe[1]; the second, which stimulates biting action, occurs in the methanol-soluble fraction of the leaves; and the third, which appears to stimulate continuous swallowing by the larvæ, is present in the fraction insoluble in methanol and soluble in water. A combination of these factors is of importance for the positive acceptance of food by silkworm larvæ. By the use of these stimulants, extracted chemically from mulberry leaves, larvæ have been induced to feed on agar.

The stimulant for biting action was first discovered in water- or methanol-extracts of young mulberry leaves, picked on a fine day, whereas in older leaves this stimulant was found to exist in an insoluble form.

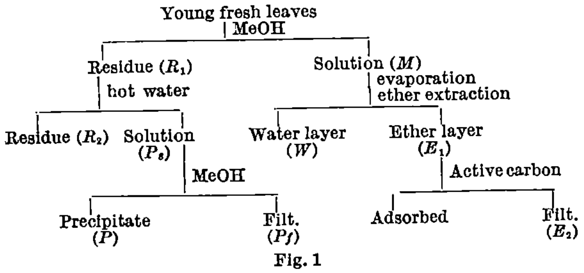

Fig. 1

Young mulberry leaves were extracted with several solvents and fractionated (Fig. 1). For the test of biting action, agar in its original state as threads was soaked in these fractions and then used as a test for biting action. In this state the agar is not soft enough to be bitten off and swallowed, so that the biting reaction can be observed on its own. Table 1 shows whether or not each fraction was observed to be a stimulant for biting action. It will be seen that the methanol-soluble fraction (M) contains this stimulant. After treating this fraction with ether, reduced activity of stimulant was observed in both ether fractions (E_1 or E_2) and in the residual water layer (W), but the total activity was recovered by mixing these two fractions. The purified ether-soluble active fraction (E_2) is a yellowish syrup with a peculiar odour.

Table 1. TESTS OF BITING ACTION

Fraction	Reaction
M	+ + + + +
R_1	+ + + + +
W	+ + + − −
E_1	+ + + − −
E_2	+ + − − −
$E_2 + W$	+ + + + +
P_s	− − − − −
R_2	+ − − − −

To test for the continuous swallowing reaction, the modified method of Thorsteinson[2] was used. That is, 3 per cent agar solution containing 1 per cent sucrose and 5 gm. of filter-paper powder was used as basal substrate. The addition of this paper powder, which enabled the larvæ to produce fæces similar to those of larvæ fed on leaves, made the test quantitative. Each fraction was added to agar basal substrates. The numbers of fæces produced overnight was taken to indicate the degree of stimulation of the swallowing action (Table 2). There was no significant difference between the numbers of fæces in experiments 1 and 2, indicating that the basal substrate was suitable for this test and that dried leaf powder may be used in place of fresh leaves. In the case of the basal diet itself, basal diet with pectin (P) or extract residue (R_2), the silkworms did not try to bite the agar at all, as shown in experiments 9–11.

Table 2

Experiment No.	Substrate	Total No. of fæces	Fæces on agar
1	Leaf powder (5 gm.)	204	156
2	Fresh leaves (10 gm.)	199	0
3	M	78	52
4	E_2	36	4
5	$E_2 + P_s$	88	52
6	$M + P_s$	186	144
7	$M + Pf$	182	121
8	P_s	37	5
9	P	40	0
10	Basal diet	27	0
11	R_2 (5 gm.)	21	0

Basal diet: 50 cm.³ of 3 per cent agar solid solution containing 1 per cent of sucrose and 5 gm. of filter-paper powder.

Dosage: Each fraction, M, E_2, P, etc., corresponds in amount to that in 5 gm. of powdered mulberry leaves.

Number of fæces: Five larvæ at the fifth stage were put in a shale overnight at 25° C. and the fæces were then collected.

In experiment 3, and especially in experiment 4, the agar contained only one stimulant for biting action, and larvæ tried momentarily to bite the agar, but did not eat continuously. From these experiments it is evident that another factor is necessary for acceptance of food by the larvæ. In experiments 6 and 7, the silkworms ate the agar continuously as if it were mulberry leaf. The agar in these experiments contained a mixture of the fractions M plus P_s or M plus P_f, respectively. From these experiments, the fractions P_s and P_f seem to contain a stimulant for swallowing action. Fraction P_s is a water-extract of the residue after treating the leaves with methanol, and fraction P_f is obtained from P_s by the removal of pectin. But, as shown in experiment 8, the presence in agar of this stimulant alone is not sufficient for its acceptance as food by the larvæ, as is also the case with the biting factor alone. Moreover, the agar containing both biting and swallowing factors, as shown in experiment 5, is also not acceptable as food. The methanol extract (M) contains a biting factor and also the volatile substances from mulberry leaves, so that in experiments 6 and 7 the agar contained all three stimulants. Thus the presence of the three stimulants is necessary for food selection by silkworms and the absence of any one of the stimulants inhibits feeding by the larvæ.

I wish to acknowledge the advice given in connexion with this work of Dr. G. S. Fraenkel.

Methods of marking *Tilapia* Spp. (Pisces : Cichlidæ)

VARIOUS species of *Tilapia* form the basis of large commercial fisheries in eastern and central Africa, and *T. mossambica* Peters has now been distributed in almost every tropical region outside Africa for culture in ponds. Simple methods of marking for individual and batch recognition can yield valuable information to such fisheries. Two marking techniques have been developed at the Inland Fishery Research Station of this Ministry during the past eighteen months, using populations of *T. nigra* (Günther) in ponds.

Individual marking. An entirely satisfactory tagging method has been evolved from techniques extensively used by the Scottish Home Department in salmonid studies. The tags are made of coloured plastic strips, 6 mm. × 3 mm., rounded at both ends, with serial numbers and letters die-stamped on either side. A small hole is drilled at one end and the tag mounted centrally with three close twists on a 5 cm. length of 0·0136-in. diameter annealed silver wire. For marking fishes, the dorsal musculature is pierced with a No. 18 gauge hypodermic needle between the roots of the first and second (or second and third) hard dorsal rays, and one end of the wire is threaded into the needle. On withdrawing the needle, the wire is brought through the muscles and the two ends of wire are twisted three or four times together against the body. The free ends of wire are cut short and both tag and securing twist are pressed back against the body of the fish. Pulling the tag tight is important, since loose tags lead to severe wounding.

Between each tagging the needle is dipped in surgical spirit, which appears adequate to prevent any infection. This method of tagging has no effect on subsequent growth, and some fishes so tagged are still alive and growing in ponds eighteen months after marking. Actual increase in length of these fishes has been as much as 20 cm. in the first six months after marking and the tags are firmly and cleanly in place. Several hundred fishes have been tagged thus in the last twelve months, and no casualties attributable to tagging have occurred, though it is not advisable to mark fish below 6 cm. total length.

Loss of tags has never exceeded 8 per cent, despite repeated monthly netting and handling of the fish. In wild populations, or those handled less frequently, the tags are probably lifelong fixtures. There has been no evidence of selective predation of tagged fishes.

This method is now being employed on a large scale for marking *Tilapia* in Lake Victoria, but a modification in this instance has been to insert the tags near the bases of the posterior hard dorsal rays in order to avoid accidental and unselective tangling of the fish, in the gill-nets used, by the ends of wire. We have also marked wild river populations of *Labeo* and *Barbus* species, well-tagged fish of each kind being re-trapped up to eight months later.

Batch marking. Individual tagging is slow (not more than 80 fishes per man per hour), and for rapid marking some form of fin-clipping is preferable. Since in *Tilapia*, dorsal, pectoral and anal fins play a part in epigamic display, only pelvic fins have been amputated; and by simple amputation of these, several hundred fish can be marked per hour. Such amputation has always been made across the proximal bases of the fin rays, since total amputation at the peduncle usually causes excessive bleeding, and may lead to infection.

In almost all cases, clipped fins have regenerated to full size, often in as little as thirty days. In less than 1 per cent of those clipped, no regeneration has occurred, possibly due to complete amputation of the peduncle. After the first month, therefore, immediate recognition of clipped fins is not possible, but nevertheless certain structural differences are apparent macroscopically up to six months afterwards and are by then probably permanent.

Table 1. DELAY IN BIFURCATION OF PELVIC FIN RAYS IN *T. nigra* AFTER FIN CLIPPING: COMPARISON IN A FISH 18·7 CM. AFTER FIVE MONTHS

	Branched rays									
	Left pelvic (cut)					Right pelvic (uncut)				
	1	2	3	4	5	1	2	3	4	5
First bifurcation	55·5	46·3	41·5	42·0	49·2	60·0	41·3	41·8	47·0	42·2
Second bifurcation										
Anterior	—	82·0	70·2	68·5	73·5	—	61·5	54·9	45·8	47·7
Posterior	—	68·5	61·0	66·2	—	—	55·8	55·5	52·0	70·0
Third bifurcation										
Anterior	—	—	—	—	—	—	79·0	82·5	78·0	—
Posterior	—	—	—	—	—	—	—	79·0	—	—
Length of unbranched ray (mm.)			17·0					19·5		
Total length of ray (mm.)	32·7	30·9	26·0	21·0	16·6	32·3	30·5	25·5	21·2	16·8

Figures refer to distance from base of ray to bifurcation expressed as percentages of total length of that ray.

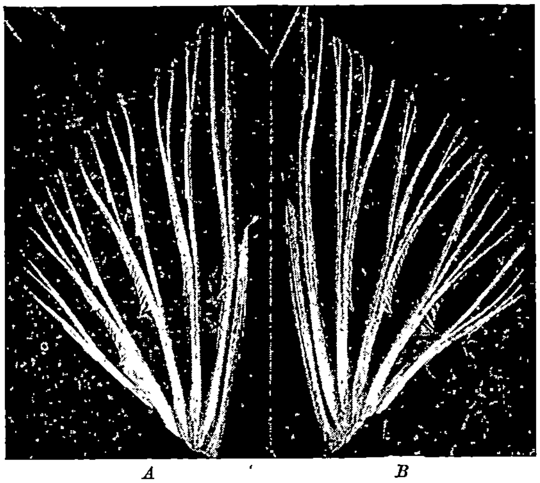

Fig. 1. Pelvic fins of *T. nigra* five months after clipping. *A*, Left clipped pelvic; *B*, right unclipped pelvic

In *T. nigra* the pelvic fin ray formula is *PI* 5. The first branched ray usually bifurcates once only (rarely twice), but the remaining four rays always bifurcate twice, and a third bifurcation may occur in parts of the second, third and fourth ray. In most cases fin-clipping does not alter the formula or number of bifurcations, but the difference between regenerated and normal fins lies in the apparent deferment of the second bifurcation (instead of very shortly after the first) in clipped fins, and possibly as a result of this, the more definite separation of the rays after the first bifurcation. Table 1 gives such differences numerical expression, and from this it is apparent that while the point of first bifurcation is little altered in regenerated fins, the second bifurcation is delayed by about 20 per cent in the anterior branch and 10 per cent in the posterior branch of the ray. This difference is easily recognizable in the field with practice. In addition, the first unbranched (spiny) ray is often slightly shorter in clipped fins, such a slight disparity being apparent even in the live fish on examination if the fins are pulled forward by these spines.

Fish used in these experiments have all shown fast growth in ponds up to 4 cm. per month, the delay in bifurcation and rapid regeneration of the fins perhaps resulting from this, although essentially the same pattern has been found in fish the growth of which has been depressed to 1–2 cm. per month. In wild populations growth may average only a few centimetres a year, and the speed and pattern of regeneration may be different. Nevertheless, the much greater numbers of fish which can be fin-clipped, as opposed to individual tagging, would lead to a higher percentage return of marked fish in commercial catches, if such catches are sampled from time to time by an observer trained to detect such differences.

Amputation of the upper lobe of the caudal fin has also been tried, but in all cases it has completely regrown and shown no structural difference to a normal fin within a month, so that caudal clipping cannot be recommended as a marking technique.

Seasonal and Tidal Fluctuations in the Trawl Catches from the Sierra Leone River Estuary

In March 1958, a series of fish-marking experiments was initiated for the first time in Sierra Leone territorial waters. Only the demersal species of commercial importance were marked, and the area chosen for the first year's liberations was the trawling ground off Robene Point, some 13 miles from the mouth of the Sierra Leone River estuary. The fish for marking were caught with a 28 ft. or 42 ft. otter trawl towed by a 28 ft. diesel-powered launch. A total of 439 hauls, each of 39 min. duration, was made during the course of the marking experiments.

An analysis of the results of the catch shows that over the whole period of the experiments, from March 1958 until January 1959, an average of 51 per cent of the catch per haul was marked, 33 per cent of the markable fish died during the trawling operation and 16 per cent were unmarkable fish such as *Arius* and *Dasyatis*, dangerous to handle. The results also show a very distinct fluctuation in the catch-rate, which was related to the tidal range—higher catches were made at neap rather than spring tides; there was no obvious relationship, however, between the rate of catch and state of tide.

Table 1. The Average Number of Fish of all Species in Each Haul during the Period March 1958–January 1959

Month	No. of fish per haul	No. of hauls
March	32	56
April	30	41
May	27	51
June	19	17
July	5	30
August	15	31
September	24	43
October	43	54
November	56	34
December	62	26
January	44	56

Table 1 gives the average number of fish of all species caught per haul. In July, a change was made from a 28-ft. to a 42-ft. net, and despite its greater catching power, there is a fall-off in the catch-rate during the wet season (May–October). A similar decline in the catch-rate was observed by two trawler firms operating in the Banana Islands area, 25 miles south of the estuary mouth—a fact which suggests that there may be a general movement of the fish stocks away from the inshore regions of low temperature and salinity at this time of the year.

There are some indications that the catch-rate may also be influenced at times by differences in the opacity of the water masses covering the grounds. Normally the water is very turbid, and Bainbridge[1], using a standard 30-cm. Secchi disk during plankton investigations in the estuary, found greater turbidity at spring than at neap tides, presumably due to the greater scouring action of the very strong (4–5 knot) tidal currents on the ebb at springs. Extinction coefficients (K–1·7/D) of as much as 3·4, corresponding to a disappearance of the disk at only 0·5 m., were recorded in the mid-estuarine region at such times. During the present experiments, observations were made at various states of the tide with a disk of a similar diameter in the Robene Point area. The readings, which have been compared with the catch per haul, are given in Table 2. From these comparisons, it will be clearly seen that there is a fall-off in the catch-rate with the clearer water, presumably due to the fish avoiding the gear. In this connexion,

Table 2. The Relationship between the Opacity of the Water and the Average Catch per Haul in the Robene Point Area during the Period September to December 1958

Secchi disk-range (m.)	Average No. per haul	N.
0·5–0·9	26	18
1·0–1·4	28	23
1·5–1·9	25	33
2·0–2·4	23	40
2·5–2·9	16	18
3·0	>3	4

it is interesting to note that over a five-day period in June, when the water in the Robene Point area was exceptionally clear, a nylon net gave a catch-rate of 110 lb. per hour and a tanned hemp net 33 lb. per hour when fished in turn from the same boat; the difference disappeared when the disk readings fell below 3·5 m.

The Amphipod, *Hyperia galba*, an Ectoparasite of the Jelly-fish, *Cyanea capillata*

Very few real facts are known concerning the relationships between the amphipod *Hyperia galba* (Montagu) and the various jelly-fish with which it is associated. Some writers have referred to *H. galba* as a parasite[1–4] but without providing any direct proof. Orton[5] assumed *H. galba* to be a food parasite, and Hardy[6] was inclined to accept this view. Stephensen[7] maintained that no amphipod except the cyamids is a true parasite, and this is the view adopted in current parasitological works of reference.

Recently, I had the opportunity to examine histologically the digestive tract of twenty-five specimens of *H. galba* from Bergen, Norway, which were obtained from *Cyanea capillata* (L.). I was immediately struck by the presence of empty nematocysts in virtually all the formed food remains encountered in the gut. As *C. capillata* frequently catches other medusae, especially *Aurelia aurita* (L.) and hydromedusae, it remained to settle whether the nematocysts came from *C. capillata* itself or from its prey. Few nematocysts pass the mouth-parts of *H. galba* undamaged, but in one specimen a number of well-preserved, discharged nematocysts were found in the atrium oris. Several of these nematocysts could be identified as heterotrichous microbasic euryteles of the type characteristic of scyphozoan medusae. Three of them which could be accurately measured were 13·2, 13·4 and 14·1μ long and 8·6, 8·6 and 9·4μ wide, respectively. Papenfuss[8] gives the average of 50 discharged euryteles of *C. capillata* as 13·6μ × 8·1μ and the normal (length ?) variation as ± 2μ. Thus the three nematocysts in question fall well within the normal range of *C. capillata* but outside that of all other scyphozoan medusae occurring in the area. One further discharged nematocyst could be identified as a haploneme measuring 17·0μ in length × 11·2μ in width. Nothing can be seen of any possible armature of the thread. The size agrees fairly well with that of the atrichous haploneme *A* of *C. capillata*, which averages[8] 18·0μ × 13·2μ. Although the hundreds of empty nematocyst capsules found in the gut cavity could not be accurately measured, they give the same general impression as a slide of macerated nematocysts of *C. capillata*, while a similar sample from *A. aurita* looks rather different, the capsules being much smaller. A very small number of nematocysts pass the intestine undischarged. Generally, they are rather distorted, and in no case has it been possible to measure them with satisfactory accuracy. Some of them could be identified as euryteles.

On the evidence presented above, it seems safe to conclude that *H. galba* is a true ectoparasite of the jelly-fish with which it is associated. A more comprehensive account of the observations will be published elsewhere.

The material for the present study was collected at the Marine Biological Station of the University of Bergen.

Evidence on Growth-rates obtained from Two Marked Humpback Whales

Recent estimates of the age at which whales reach sexual maturity have depended primarily on the interpretations placed on the rate of accretion of recognizable zones in certain structures such as baleen and ear plugs. Several workers[1,2] have pointed out that none of the ageing methods for any species has yet been standardized against organs from whales of known age. Only whales marked as calves would be of accurately known age at the time of capture, but no such animals have yet been recovered. However, two marked humpbacks caught in Cook Strait, New Zealand, have each provided material from immature animals of known minimal age.

A male humpback (mark No. 12092), was marked in Foveaux Strait, 46° 25′ S. on November 7, 1955, when it was travelling southwards, presumably towards the antarctic feeding grounds. At the time of marking it was estimated to be 36 ft. in length, a figure which later proved too high yet confirmed that the whale was not one of the young suckling calves often encountered in Foveaux Strait[3] at the time of southward migrations. It is therefore very probable that this animal had been born in the subtropical or tropical breeding areas not later than the second winter preceding its marking, and it would therefore have been in its second year at a minimum at the time of marking. On recovery at Cook Strait when it was northbound 19 months later[4] (June 18, 1957) this specimen could be assigned a minimum age of 3 years. The baleen showed three well-defined zones (Fig. 1) consistent with the now generally accepted

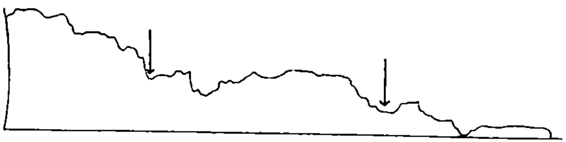

Fig. 1. Baleen tracing from a male humpback of 34 ft. 7 in. showing the three zones regarded as annual increments

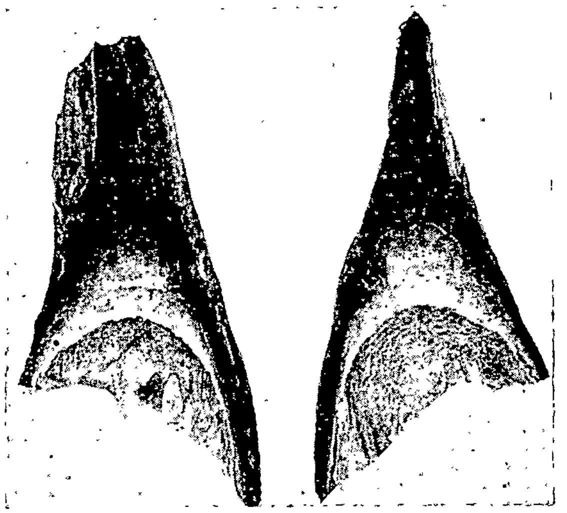

Fig. 2. Section of wax ear plug from the same animal as in Fig. 1. Five distinct and indistinct zones are present

view that baleen adds one zone annually. The wax ear plug, which was rather soft, showed 5 distinct and 2 indistinct laminations (Fig. 2), which agrees satisfactorily with the hypothesis that two ear-plug laminations are formed per year.

The standard length of this humpback at the date of capture was 34 ft. 7 in., and the mean weight of the testes was 1·36 kgm., that is, 0·64 kgm. less than the mean weight of 2 kgm. at sexual maturation[5]. In addition the seminiferous tubules were still closed. While the length at which sexual maturity occurs in male humpbacks off West Australia has been shown to be 36 ft. 9 in.[5], I have found that results from 336 males caught from the same New Zealand stock as that from which this marked specimen was recovered indicate a mean length of 38 ft. 0 in. at this stage. Only three males of less than 37 ft. have been found mature in New Zealand catches while four exceeding 39 ft. were immature, so it is clear that the marked animal was substantially smaller than the size at which sexual maturation is normally achieved. When considered in conjunction with the size of testes and closed seminiferous tubules, these results indicate that the marked humpback would have been very unlikely to reach sexual maturity during the following few months in subtropical waters. However, it could possibly have matured during the subsequent winter, 12 months later, when it would have been a minimum of four years old.

A northbound female humpback was marked in Cook Strait (No. 12043) on May 31, 1955. The phase of migration and the fact that it was not a calf indicate that the animal was then at a minimum age of approximately one year. On recovery in Cook Strait exactly 12 months later this whale was 36 ft. in length, with a total ovary weight of 330 gm. While Chittleborough[6] found a mean length of 38 ft. 6 in. for female humpbacks at sexual maturity off west Australia, 426 pairs of ovaries from New Zealand catches examined by me indicate a mean length of 39 ft. 6 in. in the latter region, where only three females of less than 39 ft. 0 in. have proved to be sexually mature, with six females between 41 ft. 0 in. and 42 ft. 6 in. still sexually immature. While there is much individual variation in ovary weights, those from the specimen under discussion were approximately half the weight of the smallest pair listed for a mature humpback[7], and the maximum follicle sizes (18 and 22 mm.) were substantially less than the 30 or more mm. which normally indicates approaching follicle maturation. Follicles of similar sizes to the above have been encountered by Chittleborough[7] in female humpbacks as small as 33 ft. The available results nowhere indicate the approach of sexual maturity within the breeding season commencing at the time the animal was caught. Since the whale would have been at least three years old at the subsequent breeding season, a minimum of three years appears to be required to reach sexual maturity. This figure would have to be raised if the animal was (*a*) more than a year old when marked, (*b*) more than one year under the age at which it would have been mature, or both (*a*) and (*b*). Baleen and ear plugs were unfortunately not obtained from this whale.

The age of sexual maturation indicated by the histories of these two marked humpbacks is substantially greater than the estimate of two years[8] which has long been accepted, but falls within the estimate of 3–4½ years for females[2] calculated after analysis of recent material using indirect methods. No recent estimate for male humpbacks appears to have been published, but the minimal figure of 4 years indicated by the marked whale here described is double that obtained by Matthews[8] for both male and female humpbacks.

Thanks are due to Mr. G. T. Perano and Mr. C. Huntly for material and information relating to the above whales and to Dr. R. G. Chittleborough for preparing the baleen tracing and for his helpful comments on this and the wax ear plugs.

Genal Cæca of Agnostids

Genal cæca are lateral appendages of the stomach of trilobites and are interpreted as hepatic glands. These glands are not fossilized but are preserved as delicate imprints of veins in the trilobite test. Genal cæca have been found in many trilobites, especially in Cambrian ptychopariids. In agnostids, however, genal cæca have not been described as yet.

In many agnostids (Fig. 1) the surface of the cheeks is wrinkled. The wrinkles form a coherent radiating 'ornament' of narrow furrows—scrobicules, and wider branching swellings—the rugæ. Each cheek has a ramified leaf-like set of rugæ which represents a symmetrical pair of alimentary glands. These glands are homologous with the genal cæca of other trilobites. In agnostids they are connected with the stomach by one pair, or two pairs, of short diverticular ducts. The scrobicules, which are furrows on the outer surface of the test, represent parietal septa on the inner surface. These septa, with

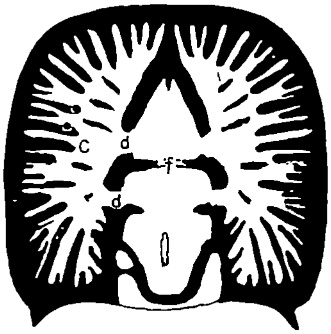

Fig. 1. Cephalon of a Middle Cambrian agnostid (*Ptychagnostus*). *C*, Cæcal glands; *d*, diverticular ducts; *f*, transverse glabellar furrow. Parietal septa (scrobicules), dorsal furrows, and border are shown in black; the cæcal glands, diverticula and bipartite stomach (glabella) are left white

mesenterial membranes attached to them, served as partitions to keep the glands in position. The stomach was located in the glabella, as in other trilobites, but in the agnostids was divided by the transverse glabellar furrow into two connected cavities.

The pattern of the cæcal glands of agnostids is simpler than that of other trilobites and has a great similarity to the cæcal glands of such arthropods as *Burgessia* Walcott and *Naraoia* Walcott. It should be noted that the pygidia of agnostids were provided with similar glands.

Intestinal appendages have been observed as impressions on the test of the thorax and the pygidium in Australian Cambrian ptychopariids as well. It is already evident that the intestinal appendages of trilobites had a segmental distribution and that each segment had two pairs of them.

A full account will be given in a forthcoming paper. This communication is published with the approval of the Director, Bureau of Mineral Resources Geology and Geophysics, Department of National Development, Canberra.

Life Span of Individual Yeast Cells

THE division of a yeast cell by budding gives rise to two cells which are identifiable, that is, the mother cell from which the bud arose, and the daughter cell which developed from the bud. The wall of the daughter cell presumably is synthesized *de novo* while that of the mother cell retains all or at least part of its identity through the division—an example of linear inheritance[1]. That the wall of the mother cell is not reformed is evidenced by the accumulation of scars associated with each budding event[2]. Electron micrographs[3-5] reveal a scar area that is approximately 1 per cent of the surface area of the cells. If, as indicated by Barton[2], a bud is never formed at the site of a scar, then it is possible that the life-span of individual cells would be limited by depletion of available budding sites. Barton observed one cell to bud 23 times but did not observe a cessation of budding. Other progressive changes also might limit the number of divisions that a single cell can complete. This report describes an experiment designed to determine the life-span of single yeast cells and includes consideration of possible mechanisms for life-span limitation.

A hybrid diploid culture of *Saccharomyces cerevisiae*, *X*30, was used for the entire study. The procedure of life-span analysis was as follows:

A layer of growth medium (0·5 per cent yeast extract, 1 per cent dextrose, 2 per cent agar) was spread on the surface of a 22 mm. × 22 mm. coverslip and a loopful of a dilute suspension of cells was streaked along one edge of the surface of this agar layer. The coverslip was then inverted over a micromanipulation chamber, maintained at 30° C.

With the aid of a micromanipulator, a number of budding cells were drawn into the central region of the agar. The coverslip was then removed, and the agar containing the original inoculum was cut off leaving only the selected budding cells. The coverslip was again placed in position, and the orientation of the buds on each of the mother cells was recorded. The cells developing from these buds were used as starting mother cells and the original mother cells were drawn to the edge of the agar layer. As new buds appeared on the starting mother cells, their positions were recorded, and when they had budded again they were removed. Only when the mother cell and its daughter have each budded can they be separated[6], so bud removal was always delayed one generation. A strip of agar containing the discarded cells and their descendants was periodically cut away from the main agar layer to limit the rate of depletion of the medium. To estimate generation times, the starting mother cells were examined at frequent intervals and the times of appearance of buds recorded. Each of the starting mother cells was followed until it failed to bud further. The total number of buds produced was considered the life span.

A total of 36 mother cells was observed, and the number of buds each produced is shown in the histogram (Fig. 1). A mean life-span of 23·9 generations with a standard deviation of 8·3 generations applies to this distribution. After three or four generations the mother cells were easily distinguished from their mature buds. They were considerably larger than first-generation mother cells, as observed previously[3]. Also surface irregularities that were

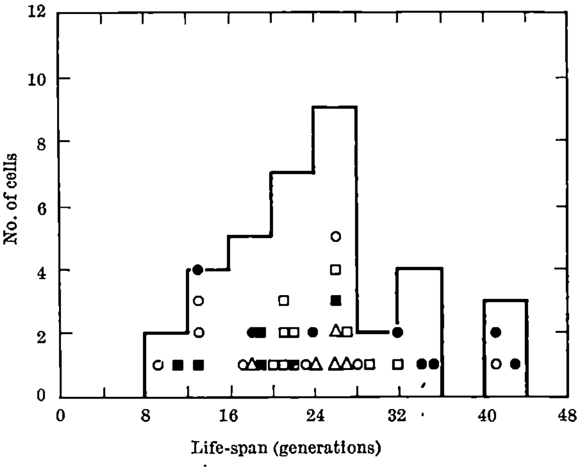

Fig. 1. Life-span distribution for single yeast cells. The different symbols represent separate experiments, except for the open and closed circles. The starting mother cells of the latter series (●) were derived from the first buds of the starting mother cells of the former (○)

most likely due to bud scars were easily seen. Throughout most of the life-span of the cells, the generation time varied between 60 and 100 min. However, the final one to three divisions of nearly all the cells were found to be much longer in duration, some lasting up to 6 hr. With cessation of budding, most of the cells became granular and some lysed. Both of these observations indicate death of the cell.

That the surface area of the cells increases with repeated budding suggests that the bud scar does not replace a portion of the original cell wall but instead fills a region that has been opened in the cell wall during bud formation. If this is the case, limitation of life-span by depletion of available regions for budding would seem less attractive as a hypothesis. Also it would be difficult to account for the wide range of life-spans observed on the basis of this hypothesis. If it is assumed that the scar regions are not active in metabolic exchange between the cell and its environment, a possible explanation of the results could be that the active surface-to-volume ratio decreases below a level necessary to maintain normal metabolic processes, thus precipitating death of the cell. The very long terminal divisions could easily be accounted for on the basis of this hypothesis.

Alternative hypotheses based on random occurrence and accumulation of deleterious nuclear events such as nondisjunction or recessive lethal genetic changes, or on random depletion of essential autonomous cytoplasmic constituents, were considered less plausible since the original population should already be in equilibrium with such events, and the death-rate per generation would be expected to remain constant.

This work was carried out under contract with the U.S. Atomic Energy Commission.

SOIL SCIENCE

Swelling of Clay–Water Systems

CLAY–WATER systems are such that care must be taken to distinguish between systems which describe the final reproducible hysteresis loop and those systems which can be regarded more appropriately as having a gel-like structure.

In a series of papers, Bolt *et al.*[1–3] have reported film thicknesses for clays saturated with sodium or calcium ions. Their results have been obtained in the main by the drying of clay materials from the gel state. Croney and Coleman[4] and also Holmes[5] have clearly demonstrated that in order to obtain the final reproducible hysteresis loop for a clay material it must be dried to its shrinkage limit. Even after drying to a terminal pressure approaching 40 atm., the water content obtained by Warkentin, Bolt and Miller[3] for a Ca^{2+} montmorillonite, on rewetting to a hydrostatic suction of 0·1 atm., is still extremely high. Water contents obtained in this laboratory using Ca^{2+} montmorillonite (Redhill, Surrey) compressed into cores at 1,200 atm., then taken through wetting and drying cycles from 0·01 atm. suction to complete desiccation over phosphorus pentoxide to obtain the final reproducible hysteresis loop are very much less than those obtained by the workers at Cornell University. Furthermore, in calculating the film thicknesses from their data, these authors have assumed that the water retained by the clays was uniformly spread over the entire surface of the montmorillonite. Thus these workers regarded the internal and external surfaces of the montmorillonite crystals as being equivalent. However, Norrish and Quirk[6] have shown that for Ca^{2+} montmorillonite the $d(001)$ spacing does not increase beyond 19 A., which indicates a film thickness considerably less than the overall film thickness calculated by Warkentin, Bolt and Miller.

Before proceeding to an analysis of the water-film thickness on a clay surface, a satisfactory model for the clay mass as a whole is necessary.

The simplest type of model is one in which the clay mass is envisaged as a porous medium; in between the pores we have a clay matrix in which the clay particles are oriented on a micro-scale. From microscopic evidence, these regions of oriented clay are of the order of one micron diameter and are randomly placed with respect to one another throughout the matrix. Each of these regions is thought of as a domain.

When such a clay mass swells without external constraint, the increase in volume arises from additional water held by the clay surfaces together with an increased pore volume caused by the expansion of the clay matrix. This increase in pore volume is regarded as being proportional to the overall volume change.

For a Ca^{2+} montmorillonite, with a total surface area of 760 m.²/gm. of which 112 m.²/gm. is the external surface of the clay crystals as measured by nitrogen adsorption, the uptake of distilled water at a hydrostatic suction of 0·01 atm. was 0·91 c.c./gm. (about 1·6 c.c./gm. was obtained by Warkentin *et al.*[3]). The volume of the oven-dry clay and the oven-dry porosity of the clay mass were measured as 0·39 c.c./gm. and 0·13 c.c./gm. respectively. Assuming that the pore volume increases proportionally to the total volume of the clay mass, the swollen porosity becomes 0·33 c.c./gm. Hence, the water content associated with the clay surfaces is 0·58 c.c./gm. A $d(001)$ of 19 A. indicates a film thickness of 4·5 A. and for an internal surface of 648 m.²/gm. this film thickness corresponds to 0·29 c.c./gm. of intracrystalline water. Thus 0·29 c.c./gm. of water are associated with the external surfaces and correspond to a film thickness of 26 A. Similar calculation using a Ca^{2+} illite clay (County Grundy, Illinois) where no intracrystalline swelling is involved gives a value of 36 A. for the water film thickness on the illite surface. These film thicknesses could probably be 5–10 A. greater, since an appreciable proportion of the porosity measured in the dry state arises from incomplete contact of crystal cleavage faces, thus giving rise to an over-correction for swollen porosity.

The magnitude of these film thicknesses clearly indicates that the diffuse double layer concepts[7,8] are not applicable to the swelling of clay systems saturated with calcium ions. Furthermore, the reduction in swelling with increasing electrolyte concentration is considerably less than would be expected from diffuse double layer concepts. This is particularly noticeable for the Ca^{2+} illite, where swelling is not reduced until concentrations in excess of M calcium chloride are used. Calculations reveal that the London–van der Waals forces are not sufficient to explain the attraction between clay crystals at separations of this order and it appears likely that further development of the ideas of electrostatic attraction proposed by MacEwan[9,10] are necessary to explain the attractive forces in Ca^{2+} clay systems.

The ideas of pore swelling and the organization of a clay on a domain basis have important implications with respect to the soil mechanics concept of soil strength and soil–water hysteresis other than the final reproducible hysteresis loop. As a clay–water system dries from a situation approaching the gel state, the formation of domains of oriented crystals and the subsequent re-orientation of these domains to positions of minimum potential energy cause the actual pore volume of the mass to decrease continually. On rewetting from positions on the normal consolidation curve with different basic pore volumes the domains retain their entity and swell as such, causing the pore volume to swell proportionately to the overall volume of the clay mass and giving rise to a series of hysteresis loops. This also enables the same water content (voids ratio) to be obtained with quite different structural arrangements within the clay mass and must of necessity result in appreciable differences in the strength of the soil structure depending on the ratio of the water held in pores to that held within the domains. It is suggested that the concepts of domains and pore swelling obviate the necessity of latent interparticle forces as postulated by Parry[11].

The form of the hysteresis loops can be explained on the basis of Everett and Whitton's[12] domain theory of hysteresis.

The idea of domains as proposed here leads to a much better appreciation of the role of organic matter in bringing about stable aggregation in agricultural soils[13,14]. The polymeric molecules in soil organic matter are thought to exist as binding between adjacent domains.

The detailed presentation of the work discussed here will be published shortly.

CHEMISTRY

Nylon Capillary Columns for use in Gas-Liquid Chromatography

The use of long, coated capillaries in gas-liquid partition chromatography was first suggested by A. J. P. Martin[1] and was developed by M. J. E. Golay[2]. Compared with the conventional packed columns, coated capillaries have provided a means of obtaining very high efficiencies with comparatively small retention times. Results that have so far been published[3] have been obtained from capillaries constructed from metal or glass (Desty, D. H., unpublished work).

The characteristics of a material suitable for constructing capillaries for gas-liquid partition chromatography are as follows: (1) the substance should show little or no adsorption to either the liquid phase or the solutes to be separated; (2) the surface of the material should be 'wettable' by the liquid phase; (3) the material should have a practical range of operating temperature; (4) the material should be capable of being drawn into capillaries of narrow diameter and even bore, with a smooth internal surface; (5) the material must have sufficient mechanical strength for the apparatus to be robust.

Nylon has these necessary characteristics if the capillaries are to be used in the separation of hydrocarbons. Nylon capillaries 0·01 in., 0·02 in. and 0·1 in. in diameter and 100 ft. long were investigated for use in the gas-liquid chromatographic analysis of aliphatic and aromatic hydrocarbons. At 23° C. these columns were found to show no adsorption effects with paraffins, and little or no adsorption effects with aromatic hydrocarbons. Benzene and toluene were eluted from an empty column with the 'air-peak', *p*-xylene showed slight retention, while cumene (boiling point 152° C.) showed more distinct retention. A maximum efficiency of 5,000–6,000 theoretical plates was obtained from the 0·1 in. diameter column, whereas the 0·01 in. and the 0·02 in. diameter columns both gave maximum efficiencies of 50,000 plates. The efficiency of these columns, however, decreased with retention time. The exact cause of this decrease has not yet been ascertained, but results suggest that it is due to a form of overloading.

From the results obtained from the 100-ft. columns, it became apparent that a column 1,000 ft. in length

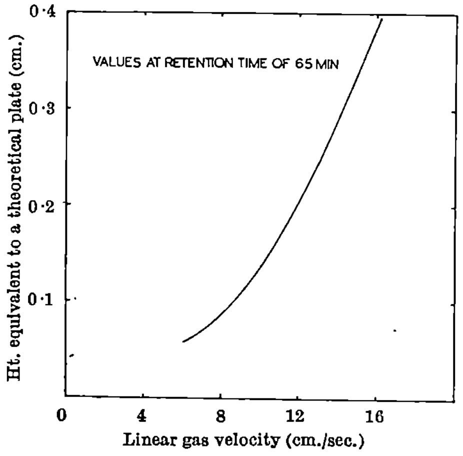

Fig. 1. Graph of height equivalent of a theoretical plate against linear gas velocity for 1,000-ft. nylon column

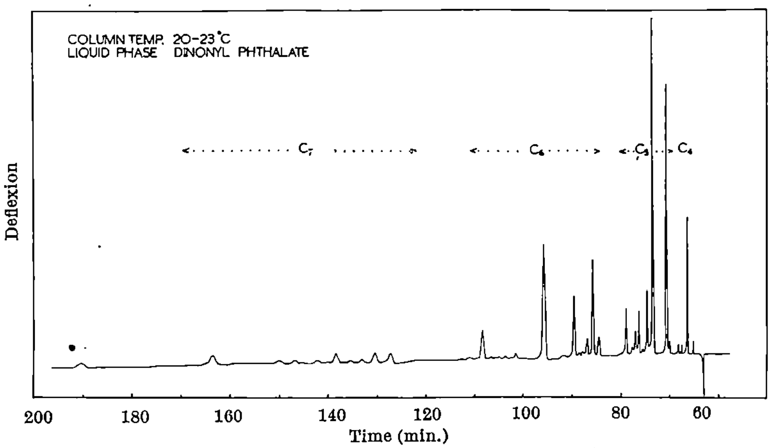

Fig. 2. Chromatogram of petroleum fraction (boiling up to 100° C.) from 1,000-ft. nylon column

should give an efficiency of between $\frac{1}{2}$- and 1-million plates. To reduce the pressure differential across the column, the 0·02 in. diameter capillary was chosen, and 1,000 ft. was coated with dinonyl phthalate by passing a 10 per cent w/v solution of dinonyl phthalate in ether through the column. At a room temperature of 20–23° C., this column was found to give a maximum efficiency of three-quarter million plates for butane, which was eluted in about 60 min. This efficiency fell to about half-million plates for *n*-hexane, which was eluted in about 90 min., and finally to 250,000 plates for *n*-heptane, which was eluted in about 170 min. A curve relating the height equivalent of a theoretical plate for this column to gas velocity is shown in Fig. 1, and a chromatogram for a petroleum fraction boiling up to 100° C. is shown in Fig. 2. The micro-argon detector was used with this column and the apparatus was found to function satisfactorily up to 100° C. A type of nylon is available, however, that is stable up to 180° C. Results have indicated that the column is slightly porous to water vapour. This can be reduced by previously coating the inside of the column with an inert 'epoxy' resin.

Full details of the work will be published later.

Analysis by Gas Chromatography of a 'Pure' Sample with an 'Impure' Carrier

A recent analysis problem involved the measurement of trace components in a 'pure' gas stream. It was decided to attempt to analyse the stream by gas chromatography. However, no gases more pure than the plant stream were available commercially, and laboratory attempts to produce a plant stream of even higher purity on a continuous scale were not satisfactory.

It was then argued that if a gas stream of known purity were used as the carrier, 'negative peaks' were possible when deficiencies of components occurred in the sample compared with the carrier.

In theory this seemed possible, if it was assumed that impurities in the carrier gas sample formed an equilibrium down the column. On injection, the replacement of a volume of carrier gas by an equal volume of gas containing the same impurities in a lower concentration would disturb the equilibrium. Furthermore, these disturbances in any one component would travel down the column in the same manner as would a higher concentration.

In order to verify this experimentally, argon was used as the gas under investigation; it contained nitrogen, oxygen, hydrogen and methane in the 0–50 p.p.m. range as impurities. Separation was achieved using an 18-ft. column of Linde's molecular sieve No. 5 *A* with a flow-rate of 2 l./hr. Detection was by means of my design of gas discharge cells. Mixtures of the impurities were made up in argon and carefully analysed by a mass spectrometer, which served as a check on the initial mixing calculations. Choosing the mixture with an intermediate concentration of impurities as the carrier, and the low and high concentrations alternately as the sample, series of negative and positive peaks were obtained for which the calibrations were approximately the same.

Thus, the chromatographic analysis was proved possible of a gas containing impurities using a carrier gas with the same impurities in a higher concentration. For a practical application it was found possible to use a cylinder of plant gas, analysed by mass spectrometer, as the carrier gas; when the plant stream was analysed, its deficiency or excess of any component when compared with the carrier was recorded as a negative or positive peak.

Micro Determination of Calcium

I am grateful to Dr. G. J. van Kolmeschate, of the Analytical Institute, Delft, and to Drs. H. A. Flaschka and A. J. Barnard, jun., of the Georgia Institute of Technology, and the Baker Chemical Co., New Jersey, respectively, for directing my attention to the fact that the indicator used by me[1] for the micro-determination of calcium is Eriochrome Black *T*, and therefore well known in this connexion. For this I express my regret: the error was due in part to discrepancies in the literature. However, although the use of this indicator is evidently not novel, my results show that it is possible to use it at *p*H 12–13, where other workers have found it unsatisfactory; I have therefore found it possible to determine calcium directly in the presence of magnesium. Possibly my ability to obtain a satisfactory end-point is due partly to carrying out the titration in essentially a thin film, and partly to using a high concentration of indicator—5λ of a 0·4 per cent methanol solution, or about 40 times the concentration used by Hildebrand and Reilly with 'Calcon'[2]. In this respect I find Eriochrome Black *T* to be superior to the latter indicator at such micro-levels. With the very small volumes involved, the coloration of 'Calcon' is undetectable at the recommended concentration: and using this indicator sufficiently concentrated to produce a visible coloration leads to gross inaccuracies which the use of blank determinations cannot correct at the calcium-levels it is desired to estimate. On the other hand, the high concentration of Eriochrome Black *T* required to give a detectable colour apparently does not affect the accuracy of the results.

Lowest Oxidation States of Technetium and Rhenium

The polarographic reduction of perrhenate ion, ReO_4^-, to rhenide ion has been studied in some detail[1,2]; although the possibility of a −I state for technetium has been mentioned[3], no experimental evidence for such a state appears in the literature.

The polarographic reductions of potassium perrhenate and pertechnate in 2 *N* potassium chloride have been compared. For perrhenate, Lingane[1] found that the reduction wave was considerably larger than that expected for an eight-electron reduction to Re(−I), although he found that the *n* values tended towards this value with increasing concentration. Our results agree with Lingane's in dilute solutions, but at concentrations greater than 0·5 m*M* the reduction wave corresponds exactly to an 8-electron reduction.

For potassium pertechnate in 2 *N* potassium chloride, an 8-electron, irreversible, diffusion-controlled reduction very much the same as for perrhenate is observed, clearly showing that reduction to a −I oxidation state occurs. In dilute solutions, technetium shows a similar effect to rhenium in that the *n* values become greater than 8, although this does not occur until concentrations in the range of about 0·025 m*M* are reached. The half-wave potential of the single wave varies slightly with concentration, being −1·15 V. at 0·1 m*M* and −1·12 V. at 0·01 m*M*. The wave is well defined and would be suitable for the determination of technetium in concentrations down to 1 p.p.m.

The nature of the reduced rhenium species has generally been considered to be Re^- or $[Re(H_2O)_4]^-$, and solid rhenides have been isolated[4,5]. However, we have found that aqueous solutions of perrhenate reduced by sodium amalgam show a well-defined proton resonance in the high-field region characteristic[6] of transition metal to hydrogen bonds at ~850 cycles/sec. vs. water at 56·45 Mc./sec.; aqueous solutions of a solid rhenide after passing through a cation resin column have also been found (Ginsberg, A. P., and Miller, J. M., Columbia University, New York, personal communication) to give a similar resonance line.

In alkaline solution, therefore, the reduced 'rhenide' species contains an Re—H bond; this finding also shows that the presence of strong field ligands such as carbon monoxide, substituted phosphines, or cyanide, which are also bound to the metal atom in all previously known transition-metal complex hydrides, is not a pre-requisite for the formation of a transition metal-hydrogen bond in a complex compound.

While the precise nature of the anionic species is not known, if we accept the analytical data of Floss and Grosse[5] for the solid rhenides, namely, $Li[Re(H_2O)_4]$, then it seems reasonable to assume that the species are of the type $[HRe(OH)(H_2O)_3]^-$, $[H_3Re(OH)_3(H_2O)]^-$, etc.

Technetium may prove to form similar species. Details of this work will be published elsewhere.

We are indebted to the U.K. Atomic Energy Authority (R. C.) and the Department of Scientific and Industrial Research (W. P. G.) for maintenance grants, and to the Atomic Energy Authority and Johnson, Matthey and Co., Ltd., for the loan of technetium and rhenium, respectively.

Effects of Electron Bombardment upon Bromides of Cadmium and Silver

Some interesting effects of electron bombardment upon certain inorganic substances were reported by de Souza Santos[1]. I have also observed rather similar phenomena with silver bromide and cadmium bromide under the electron microscope, although the type of reaction is not the same as that in de Souza Santos's experiments.

Electron bombardment of silver bromide causes local reduction to metallic silver and the reduced silver tends to gather locally[2].

In addition, cadmium bromide is photosensitive[3]. Electron bombardment reduced it to metallic cadmium[4]; the reduced metal consists of very minute crystals and keeps closely to the original form of the cadmium bromide[5]. In my experiments special care was taken that the specimen of cadmium bromide was not in contact with the film supporter in the electron-microscope or diffraction apparatus, but was held in space by a wire mesh.

Thus different metals reduced by electron bombardment behave differently, an effect that I am inclined to attribute to differences of crystal structure. Silver bromide crystallizes in the rock-salt structure, whereas cadmium bromide possesses a hexagonal layer structure which is anisotropic[6]. Fig. 1 shows the reductive process due to electron bombardment in the (001)-plane of cadmium bromide, where the formation of triangular and hexagonal holes occurs. These suggest the existence of an effect of crystal structure on the morphological changes produced by electron bombardment. The anisotropy of the crystal

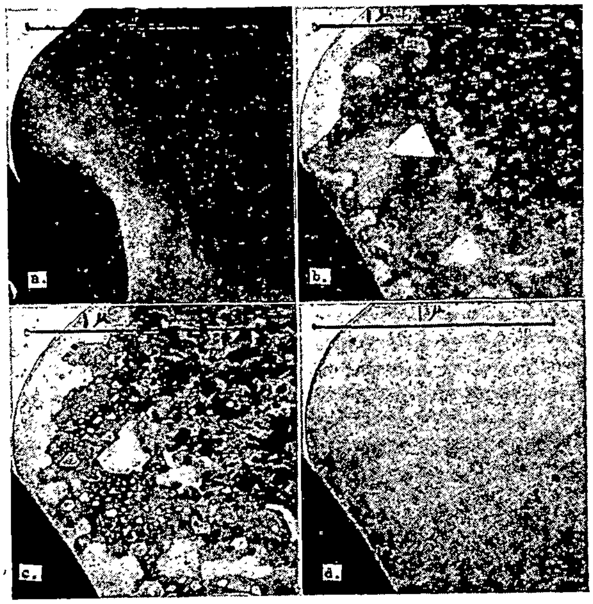

Fig. 1. Electron micrographs of same portion of (011)-plane of cadmium bromide crystal. (*a*) Before electron bombardment; (*b*) formation of triangular holes followed later (*c*) by hexagonal holes; (*d*) specimen becomes transparent to electrons. (× 3,200)

structure of cadmium bromide apparently controls the mobility of the reduced metal, so that the initial structure persists even after reduction of the original salt.

The morphological questions raised by de Souza Santos's electron bombardment experiments should be considered in the context of the crystal structure of the specimens.

PHYSICAL SCIENCES

Advance Detonation in a Tubular Charge of Explosive

A GENERAL study of the effects of a void within an unconfined solid explosive on its detonative properties was made in these laboratories in 1941 and later; some new observations were made. One effect, as shown by rotating-mirror camera records, is that the velocity of detonation of a tubular charge is higher than normal; for example, with a cylindrical charge of cast 40 : 60-tetryl/T.N.T. (density 1·62), 1¼ in. in external diameter, with an open axial cavity, 14 in. long and ¼ in. in diameter, the steady velocity of detonation in the tube wall is 7,410 m./sec., as compared with the normal rate of 7,125 m./sec. in a solid cylinder of the same diameter[1]. Inside the cavity in these conditions a luminous phenomenon (recorded by the camera because of the translucency of the explosive) travels at a sensibly constant speed of about 12,500 m./sec., and thus out-distances the detonation wave in the wall. In the open, beyond the end of the tube, the effect is recorded as an intense flame having temporarily a still higher speed.

The results of further experiments with tubular charges are now also briefly reported; in many of them I was associated with W. B. Cybulski, (the late) W. Payman and H. Titman. First, the effects described above were frequently observed and found to vary in magnitude with the dimensions of the charge and cavity and with the nature and physical condition of the explosive. As an example of the order of the effect with a low-density charge, when fine tetryl crystals are lightly compacted (density 0·93) as a tube formed between two sleeves of 'Cellophane' ¼ in. and 1¼ in. in diameter, the velocity of detonation in the tube wall is greater than the velocity in a solid cylinder by 47 per cent; the respective values are 7,870 and 5,370 m./sec.

Secondly, the result of closing the further end of the cavity with explosive was examined. If the tube and the blocking pellet are of an adequately sensitive explosive (for example, the above tetryl/T.N.T. mixture) the result shown in the photograph in Fig. 1 may be given (film writing-speed 352 m./sec.). Three detonation waves, indicated as *A*, *B* and *C* in the diagram, can be distinguished in addition to the luminous cavity wave. The latter again precedes the annular detonation wave *A* travelling in the tube wall, and its impact with the blocking pellet is followed by the initiation of the two detonation waves *B* and *C*; the former travels on through the final pellet and the latter in the reverse direction

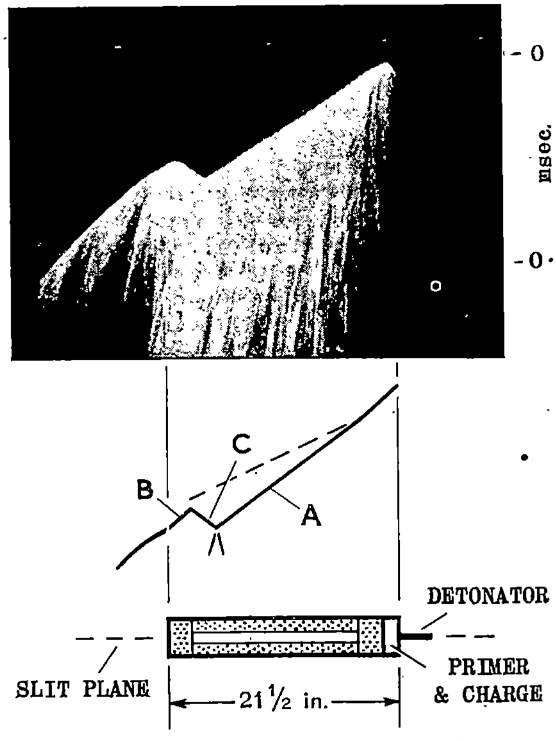

Fig. 1. Charge with single cavity and end initiation
(*Crown copyright, S.M.R.E.*)

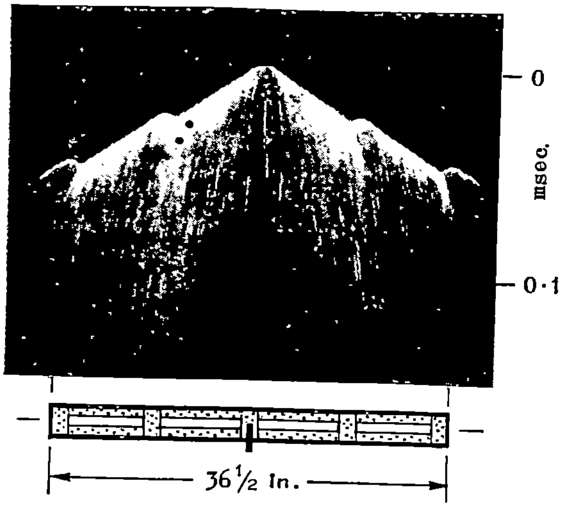

Fig. 2. Multiple-cavity charge with central initiation (*Crown copyright, S.M.R.E.*)

through the tube wall towards the oncoming wave *A*. The eventual collision of waves *A* and *C* is accompanied by a sharp increase in the brightness of the flames. The brief time-interval that elapses between the arrival of the internal wave at the end of the cavity and the first appearance of a detonation wave in the end pellet does not necessarily represent a delay in initiation; it is no more than the time that would be required for the detonation to spread spherically from a region of inception near the axis to the surface.

This phenomenon can be called 'advance detonation'. It occurs with a variety of explosives, including tetryl and gelignite, but not with those of comparatively low sensitivities nor in thin-walled tubes. Indeed, with T.N.T. of coarse crystal structure and cast without additive, not only is advance detonation absent, but also the oncoming detonation wave *A* is extinguished at the end of the cavity and all flame disappears; furthermore, wave *A* may fade before reaching that point. Border-line effects, such as an advance detonation that is delayed or proceeds in one direction only, are given by explosives of intermediate sensitivity, for example, cast tetryl/T.N.T. mixtures containing less than 30 per cent of tetryl.

Similarly, intermediate effects are given even with tetryl in charges having long or narrow cavities; in these conditions the cavity wave begins to lose speed. The attenuation is evidence of a drain of energy to the wall of the cavity, a result that is doubtless related to the enhanced velocity of detonation in the tube wall (wave *A*). The occurrence of detonation in the wall of a tubular charge with an open end, as the result of the above loss of energy, can be observed only in special circumstances, for example, with explosives at a low packing density (and therefore in a very sensitive condition) and when wave *A* has been extinguished by an annulus of inert material that has been interposed as part of the tube. Advance detonation in the wall sometimes occurs in these conditions after a comparatively long delay.

The conditions in the cavity resemble those in which advance ignition has been observed in detonating gas mixtures contained in cylindrical tubes when a shock wave, travelling ahead of the flame front, reaches the closed end of the tube; the collision of the wave with an obstruction may result either in the inflammation of the gas mixture[2] or in its immediate detonation[3]. It is concluded that the cavity wave is the sole cause of advance detonation in a solid explosive, and that at the surface of the blocking pellet struck by the wave there is a rapid and substantial transformation of energy following the impact. The cavity wave must also be the cause of the enhanced velocity of the detonation in the tube wall, possibly through the pre-compression of all or some of the material of the wall.

Some conclusions of practical importance can be drawn from these experiments. With an insensitive explosive such as T.N.T., cavitation is shown to be undesirable; it must represent in any event a loss of explosive power, but there may be a further more serious loss because of a complete failure of part of the charge to detonate. With the advance detonation that occurs with more sensitive explosives, however, some control of explosive action is afforded by cavitation, although again a net loss in total power can be expected. The detonation of a tubular charge is completed in a shorter time than that of a similar solid charge, thus leading to enhanced explosive action or greater brisance; from a knowledge of the velocities of the various waves, the length of the cavity can be chosen to give a minimum total detonation time. Further, the ring of collision of waves *A* and *C* can be regarded as a focus of brisance; multiple cavities in cascade can be used to produce a succession of such localities where desired.

These secondary results of advance detonation are illustrated in Fig. 2, which records the detonation of a suspended charge of pressed tetryl (density 1·45), ⅞ in. in diameter, and containing four separate axial cavities each 8 in. long and ¼ in. in diameter; the velocity of detonation in the walls of the hollow portions is 7,780 m./sec., as compared with the corresponding velocity in a solid cylinder of 6,875 m./sec. Owing to the opacity of the tetryl the cavity wave was not recorded, but the four points of collision in the tube surface are seen. The arched trace shows that the time of detonation is further shortened substantially by initiating the charge centrally instead of at the end. In this instance the total reduction of time is 65 per cent.

It is hoped to publish the quantitative results of this work in due course.

Gelatin as a Photo-elastic Material

In recent investigations of contact stresses in the Charles Kolling Photo-elasticity Laboratory of this University, a clear gelatin specially supplied by local manufacturers was used for the models. Gelatin was selected in view of its low Young's modulus and its high relative stress–optical coefficient, despite its serious disadvantages discussed herein.

It was found that most of the difficulties of preparing homogeneous gelatin–glycerin models may be overcome if the precautions of Farquharson and Hennes[1] are carefully observed. Their suggested pouring temperature of 40° C. may be exceeded slightly without impairing the photo-elastic properties of the models.

The problem of satisfactory storage of gelatin models was systematically investigated with the following general results:

(1) *Storage in moist air.* Models containing 20 per cent gelatin and 12–14 per cent glycerin stored at room temperature in air of 100 per cent relative humidity remained reasonably stable in respect of water content, Young's modulus and stress–optical coefficient over a period of 200 hr.

(2) *Storage in dry ambient air.* Models containing 20 per cent gelatin and greater than 14 per cent glycerin stored on the bench, with a sheet of glass on each side of the model, were found to be reasonably stable for 200 hr. To prevent adhesion of the model to the glass, liquid paraffin (B.P.) was found to be an excellent lubricant.

(3) *Storage in a glass mould.* The storage of a model by carefully replacing it in its mould, using liquid paraffin as the lubricant, proved to be the most satisfactory method.

The time–edge effect[2] developed to a marked extent in all the models, and appeared to be unavoidable regardless of the method of storage. It may be overcome by cutting a thin layer from each loaded edge before each test. A very sharp blade must be used to achieve a smooth new edge.

Another problem with gelatin photo-elastic models is the rapid growth of bacteria in the gelatin, which seriously affects the contrast of the fringe patterns. To prevent the growth of bacteria it is recommended that, when preparing the models, 0·1–0·2 per cent (by weight) of sodium pentachlorphenate be added to the water before the gelatin is added.

Determination of the stress–optical coefficients with yellow sodium light (5893 A.), using a concentrated point load, yielded values in the range $2 \cdot 4 \times 10^4$ to $3 \cdot 2 \times 10^4$ brewsters for 20 per cent gelatin/12 per cent glycerin models, and $3 \cdot 4 \times 10^4$ to $4 \cdot 0 \times 10^4$ brewsters for 20 per cent gelatin/14 per cent glycerin models. These values are not altered by the presence of sodium pentachlorphenate. They appear to be appreciably greater than previously published values[3-5].

Interpretation of Resonance Energies in the Photoproduction and Scattering of Pions from Hydrogen

SEVERAL maxima are well established now in the scattering and photoproduction of pions from hydrogen[1-6]. These maxima are generally considered to be due to the excitation of the proton to 'isobaric' states.

In all cases, however, the excitation energy amounts to several hundred MeV. It is, thus, of the same order of magnitude as the meson rest energies or their differences.

In this communication an attempt is made to give a numerical interpretation of the observed excitation energies.

Recently[7] it was shown that the masses of a series of heavy fermions can be described by the relation:

$$Mc^2 = 38 \cdot 46[l(l + 1) + s(s + 1)]\text{MeV}. \qquad (1)$$

Table 1. PARTICLE REST ENERGIES IN MEV.

s		Values of *l*					
		1	2	3	4	5	6
1/2	calc.	106	260	490	798	1,182	1,644
	obs.	106	266	494	792	1,189	1,645
		μ	ζ	(K)		Σ	
3/2	calc.		375	606	910	1,298	1,760
	obs.		377	603	(938)	1,311	1,760
					(P)	Ξ	
5/2	calc.			798	1,106	1,490	
	obs.			792	1,115	1,508	
					Λ		
7/2	calc.				1,375		
	obs.				1,380		

The quantum numbers *l* and *s* are taken to represent angular momentum and intrinsic spin of extended particles.

In Table 1 calculated values are given for heavy fermions, for which comparable empirical evidence exists[8-11]. The calculated and the empirical values agree in most cases within less than 1 per cent. The deviations, if not within the experimental error, may be due to electromagnetic effects or a small quadrupole correction.

One of the most interesting features of the level scheme provided by equation (1) is the occurrence of a degeneracy of the value $E = 798$ MeV. for $l = 3$; $s = 5/2$ and for $l = 4$; $s = 1/2$. Moreover, it coincides with the difference of the rest energies of a proton and of a pion (938–140) MeV. The difference in the stability of a proton and of mesons and hyperons can thus be understood as due to the possibility of resonance in the binding of a pion to a core particle with rest energy 798 MeV.

Equation (1) can be used to explain some of the resonance energies observed in pion scattering and in the photoproduction of pions from hydrogen.

The core particle ($l = 3$; $s = 5/2$) with energy $E = 798$ MeV. can be excited to form a particle with $l = 3$; $s = 7/2$; $E = 1{,}068$ MeV. The excitation energy amounts to $E = 270$ MeV. The first maximum is found for $E = 263$ MeV. (c.m.) for charged pions produced with γ-rays of 300 MeV. (lab.)[1]. This energy can be considered to represent resonance energy in the dispersion relation for nuclear reactions[12].

The excitation of the same core particle to a particle with $l = 4$, $s = 5/2$; $E = 1{,}106$ MeV. would need an excitation energy of $E = 308$ MeV. A resonance energy in scattering of charged pions was found at 299 MeV. (c.m.). (This value represents the sum of 159 MeV. kinetic energy and 140 MeV. rest energy of the meson[2].)

The superposition of these two excitations, namely, the excitation of the core particle to a particle with $l = 4$; $s = 7/2$ would require $E = 577$ MeV. A resonance energy for neutral photopions occurs at $E = 574$ (c.m.). (750 MeV. γ-rays, lab.)[3]. A maximum at this value is reported also for π^--scattering[4].

The excitation of the core particle to a particle with $l = 3$; $s = 9/2$; $E = 1{,}414$ MeV. would require an energy $E = 616$ MeV. (M2), and $E = 615$ MeV. was found recently for a maximum in the π^--scattering by hydrogen[5].

The first four excitation energies to be expected for the core particle of 798 MeV. thus agree with four of the observed resonance energies.

The existence of resonance-levels need not be due to the excitation of the core particle only, but may be caused also by the energy absorbed for pair creation.

In fact, the first calculated resonance energy $E = 270$ MeV. coincides with the rest energy of a pair of neutral pions. Their formation provides thus an alternative interpretation or a competing process for the observed $E = 263$ MeV. (c.m.) or 300 MeV. (lab.) γ-ray resonance energy for photoproduced charged pions mentioned above.

The resonance energy for photoproduced neutral pions amounts to 320 MeV. γ-ray energy (lab.) or $E = 279$ MeV. (c.m.)[4] and $E = 279$ MeV. is exactly the rest energy of a pair of charged pions. A maximum in this energy region seems to exist also for π^+-scattering[6].

The resonance energy due to the creation of a pair of particles with $l = 2$; $s = 1/2$ would be $E = 520$ MeV. A resonance energy of $E = 543$ MeV. (c.m.) or 700 MeV. (lab.) was observed with γ-rays producing positive pions[1].

The formation of a pair of particles with $l = 2$; $s = 5/2$ would require $E = 750$ MeV., and $E = 775 \pm 40$ MeV. is reported for a maximum of scattering of negative pions[5].

Table 2 gives a survey of the calculated and observed resonance energies E_r.

Table 2. RESONANCE ENERGIES (MEV.) FOR PHOTOPIONS AND FOR PION SCATTERING FROM HYDROGEN

^{2s+1}L	^6F	^8F			^6G		^8G	^{10}F	
Mc^2	798	1,068			1,106		1,375	1,414	
(Pairs)			$2\pi^0$	$2\pi^\pm$		$2^3D^\pm$			$2^4D^\pm$
E_r calc.		270	270	279	308	520	577	616	750
E_r obs. (c.m.)		263		279	299	543	574	615	775 +40
Obs. γ-rays (lab.)		300		320		700	750		
producing		$\pi^\pm$		π^0		π^+	π^0		
Scattering of		π^+			$\pi^\pm$		π^-	π^-	π^-

The rest energy $E = 211$ MeV. of a pair of muons should lead to a maximum for pion scattering at $E = 85$ MeV. pion kinetic energy (lab.), or to $E = 235$ MeV. (lab.) for the energy of γ-rays producing pions. Anomalies in these energy regions seem to have been observed[8]. They deserve thus further investigation. The resonance line need not be narrow, since the stimulated decay during a reaction appears to be much faster than the spontaneous decay.

At any rate, all resonance energies calculated for the energy-range of the observed maxima agree with the empirical values within the experimental error, in several cases with remarkable precision.

'Ring Angels' over South-East England

IN the course of observations on radar 'angels' which we have been making during the past two years, we have occasionally noted formations of angels which are clearly related to the ring angels reported by Elder[1] at Ypsilanti (U.S.A.) in 1957. Fig. 1 shows a typical and fully developed ring angel which was observed on February 17, 1959. This record was obtained with a high-power L-band radar of conventional design; the signals were displayed on an ordinary plan position indicator with video map superimposed on the radar signals. The antenna was rotated at four revolutions per minute and the displays were photographed on each scan. If a film secured in this way is exhibited through an ordinary ciné projector running at sixteen frames per second, an acceleration of 240 times is obtained, and in these circumstances the dynamic growth of the ring angel can be clearly observed. The ring angel commences as a strong point echo; it then extends into an annular ring, to be followed by other rings at approximately equal intervals of time. The whole phenomenon has precisely the same appearance as the ripples on a pond expanding from a point of disturbance. In the case of the rings shown on Fig. 1, eighteen rings were emitted from the centre with an average periodicity of 2½ min. and a maximum diameter of 20 miles was achieved.

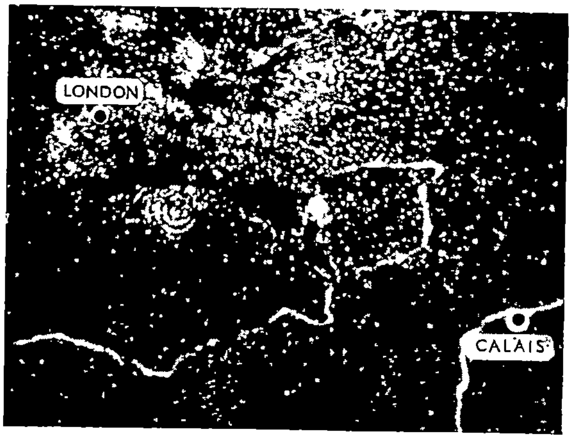

Fig. 1. Ring angel of February 17, 1959

In the course of the present work we have observed sixteen such incidents, and the geographical distribution of the active centres is shown on Fig. 2. The ring angels tend to occur around certain active regions which have been marked upon the map as small circles. The ring located at Ipswich has yielded five incidents during the past four months. Detailed examination of the map and of the areas involved has not revealed any topographical feature which might be a contributory factor to ring formation; nor are they regions of unusual bird-roosting.

It will be noted that no ring angels have been observed over the sea, and that the ranges of the rings from the radar station, when taken in association with the radiation pattern of the radar, suggest that the reflecting or scattering elements of the ring occur at a low altitude only. It has been possible to make some height measurements with the aid of a 10-cm. nodding height-finder radar. These results,

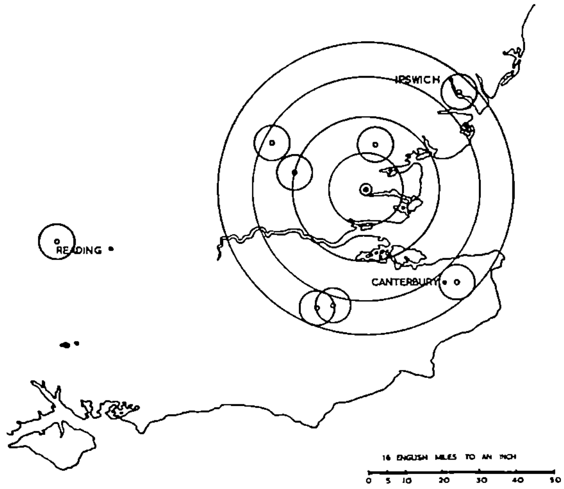

Fig. 2. Location of ring angel centres

if interpreted as heights in the ordinary manner, indicate that the altitude of the rings does not exceed 2,000 ft.

These rings show many points of similarity with those reported by Elder, but there are certain important differences, the chief of which is the time of occurrence. The rings we have observed have all occurred at the sunrise period, and in most cases the presence of the ring centres has been noted for a few minutes before sunrise. This correlation with sunrise is quite vividly seen on the radar display, since the sun shows itself as a radial noise point upon the plan position indicator and ring angels and solar noise then exist simultaneously upon the tube. We have noted as many as three incidents occurring simultaneously about the various active centres. It will not be possible to see the form of the annual variation until a year's cycle is completed in September 1959, but from our records to date there appears to be a tendency for the rings to be more prevalent during the winter months.

The rings have been observed during a variety of weather states, including widespread fog, but the ground wind-speed on all occasions has been less than 15 knots. The approximate circularity of the rings can be assessed from Fig. 1 and there has been only one formation which has shown some distortion of a form that is correlated with the wind direction; in no case has there been definitely measurable displacement of the centre of the disturbance.

Measurements on ring velocity and periodicity have been made from the film records, but no great accuracy can be claimed for the results, due to the diffuse nature of the phenomenon. The periodicity or interval between successive rings has varied from 1½ min. to 12 min. for the different active centres, while the interval has changed by as much as 50 per cent during the course of one incident, for example, from 2 min. to 3 min. The range of velocity of expansion for all the incidents so far observed is 25–55 m.p.h. In the case of the most perfect ring formation, good measurements were possible upon the first four rings emitted and these possessed velocities of 36, 30, 21 and 22 m.p.h. respectively.

As the rings expand they become very diffuse and are seldom continuous; the maximum diameter so far achieved is 30 miles. The debris from the ring then disappears rapidly and does not continue to move outward as a number of independent bird-type angels.

On the evidence which has so far been accumulated, it is difficult to decide whether ring angels are due to meteorological causes or, alternatively, are to be attributed to bird movements such as have been shown to be the probable explanation of a high percentage of ordinary radar angels by various workers, including Harper[2] and Tedd and Lack[3]. The observations are being continued and will be reported in detail elsewhere.

We wish to thank our colleagues, Mr. P. Way and Mr. G. Downie, for assistance in making the observations, and the engineer-in-chief of Marconi's Wireless Telegraph Co., Ltd., for permission to publish this communication.

Microseisms at Scott Base

Since March 1957, a seismological station has been in operation at Scott Base (77° 51′ S., 166° 48′ E.) on Ross Island. The seismometers, three Benioff-type instruments, feed three short-period (0·2 sec.) galvanometers and three longer-period galvanometers (vertical and east–west 25 sec.; north–south 10 sec.). The installation was not explicitly designed for microseismic recording, the main objective being the determination of local seismicity. However, following some interesting qualitative observations at the Base, a preliminary examination of microseismic amplitudes and periods has been made.

In Fig. 1*a* are shown, for 1958, the weekly mean amplitudes (arbitrary units) of 6-hourly microseismic activity on the short-period component of the vertical seismometer. The microseisms are 1–4 sec. period and, as is normal, periods increase with increasing amplitudes. However, abnormally, at Scott Base the maximum amplitudes occur during the summer with microseisms virtually absent during the winter on this component. This pronounced seasonal variation must be related to the presence of ice on the surface of the Ross Sea. The ice forms during autumn and breaks up in the late spring. By mid-winter, freezing of the sea is probably complete, though due to storm and tide action this cover may be broken. During late winter the pack ice is believed to extend beyond the continental shelf, thus inhibiting surface motion of the sea over the continental region.

There is little doubt that the 1–4 sec. microseisms recorded at Scott Base are due to events within the Ross Sea, which cause microseisms whenever ice conditions permit. This is in accord with Donn[1], who states that restricted storms or cold fronts over relatively shallow continental shelf waters generate microseisms of periods of 2–4 sec. Analyses of sea and weather conditions in relation to microseismic

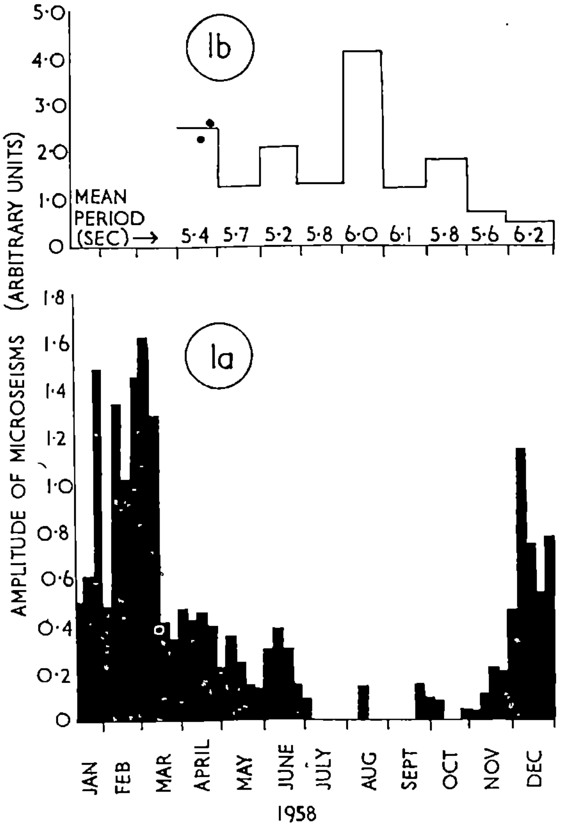

Fig. 1. (*a*) Weekly mean amplitudes of microseismic activity on short-period vertical record, Scott Base, 1958. Based on five typical groups at 00, 06, 12 and 18 hr. daily. (*b*) Monthly mean amplitudes of long-period microseismic activity on long-period north–south record, Scott Base, 1958. Based on five typical groups at 00, 06, 12 and 18 hr. G.M.T. every seventh day. Monthly mean periods are given (in seconds) at base of histogram

activity are widespread in the literature but the mechanism of generation and propagation is still unresolved and theories pertaining to it increase[2]. It may be possible to use a knowledge of the pack ice morphology (amplified by aerial photography) as a constraining factor in the examination of these theories.

Microseisms of the 4–10 sec. type appear throughout the year on the north–south component with the 10 sec. galvanometer. By taking the 6-hourly microseismic characteristics on every seventh day and computing monthly means, the histogram in Fig. 1*b* has been derived. No satisfactory values for the months of January, February and March 1958 can readily be derived for these longer-period microseisms because of interference by shorter-period activity, which follows the same seasonal pattern as that on the short period vertical record. Mean periods (in seconds) of all observations are recorded for each month.

There may be a seasonal variation of the 4–10 sec. microseisms with a minimum in the summer; the results presented are certainly insufficient to establish this. But the major point of interest is that these microseisms persist undiminished throughout the winter. Their origins probably lie in the cyclones over the oceans surrounding the antarctic continent; and it seems impossible that wave or surf action at the coast could play any part in their generation or transmission.

This communication gives a broad picture of the principal events. There are many details of interest and these will be studied extensively in the future.

Lieut. F. Faggioni, of the Italian Navy, was the seismologist at Scott Base during 1958.

A Possible Experimental Test of Einstein's Second Postulate

As is well known, Einstein's special theory of relativity rests on two postulates: (1) the postulate of relativity; (2) the postulate of constant light velocity, which says[1] "that light is always propagated in empty space with a definite velocity c which is independent of the state of motion of the emitting body". For the first postulate there is much experimental support; for the second, none. It is not generally appreciated that the experiments often held to confirm the kinematical part of Einstein's theory are, in fact, evidence that the Maxwell–Lorentz electromagnetic equations are invariant to the Lorentz transformation, since the forces and velocities concerned are determined from those equations and not by direct measurement.

In view of difficulties which have recently arisen, it is highly desirable to test the kinematics of the theory. It is often said that an experimental test of the second postulate is impossible since the clocks used would have to be synchronized by assuming its truth, but this is not so. If beams of light were emitted from the same point at the same instant from two relatively moving bodies, the postulate could be confirmed or otherwise by observing whether they arrived at a distant point together or successively; it would not be necessary to make a precise measurement of the times of travel. The frequencies need not be the same (the Doppler effect would make this unlikely in any event) provided the effect of the intervening air on the velocities was taken into account.

It might not be beyond the power of modern techniques to make this test by a purely terrestrial experiment, in which the motion of the sources remains effectively constant during the passage of the light. Forty years ago Majorana[2] attained a velocity sufficient to test the indifference of the Michelson–Morley experiment to the velocity of the source, but this, of course, only confirmed the first postulate. My purpose here is to urge the importance of making this test if possible, in view of the very great amount of theory which at present rests on an assumption.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Tuesday, June 23

Society for Endocrinology (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Prof. Charles H. Best (Toronto): "A Canadian Trail of Medical Research".*

Wednesday, June 24

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. E. G. Poole and Dr. A. J. Whiteman: "The Glacial Drifts of the Southern Part of the Shropshire-Cheshire Basin and their Status in British Pleistocene Stratigraphy".

British Psychological Society, Medical Section (at the Medical Society of London, 11 Chandos Street, Cavendish Square, London, W.1), at 8.30 p.m.—Mr. L. Z. Freedman: "Research in Psychiatry and Law".

Thursday, June 25

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5.30 p.m.—Annual General Meeting. Dr. J. A. Fraser Roberts: Presidential Address.

Friday, June 26

Ciba Foundation for the Promotion of International Co-operation in Medical and Chemical Research (at the Royal Institution, 21 Albemarle Street, London, W.1), at 5 p.m.—Prof. Pasteur Vallery-Radot (Paris): "Le Rôle de l'Intuition dans la Recherche Médicale" (11th (Annual) Ciba Foundation Lecture).

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant in Mathematics—The Secretary of University Court, The University, Glasgow (June 27).

Assistant, Grade B (with a good honours degree or equivalent, together with teaching, research or industrial experience), in Chemistry at Wolverhampton and Staffordshire College of Technology, to teach inorganic chemistry to H.N.C. and G.R.I.C. Part 1 standard—Clerk to the Joint Education Committee, Education Offices, North Street, Wolverhampton (June 27).

Lecturer (able to teach inorganic, organic or physical chemistry to Special (Honours) Degree Standard) in Chemistry—The Clerk to the Governors, Woolwich Polytechnic, London, S.E.18 (June 27).

Lecturer in Chemical Pathology—The Secretary, St. Mary's Hospital Medical School (University of London), Paddington, London, W.2 (June 27).

Lecturer or Assistant Lecturer (with special interests in organic chemistry) in Chemistry—The Registrar, The University, Sheffield (June 27).

Research Fellow in Mathematics—The Secretary of University Court, The University, Glasgow (June 27).

Lecturer (Grade II) in the Department of Physics, and an Assistant Lecturer in the Department of Physics—The Registrar, The University, Bristol (June 30).

Lecturer in Physical Chemistry—Prof. R. M. Barrer, F.R.S., Chemistry Department, Imperial College of Science and Technology, London, S.W.7 (June 30).

Lecturer in the Department of Natural Philosophy, and Assistants (3) in the Department of Natural Philosophy—The Secretary, The University, Edinburgh (June 30).

Lecturer in the History of Science—The Registrar, The University, Leicester (June 30).

Psychologist (with an honours degree or equivalent qualification in psychology, and preferably postgraduate research experience in experimental or clinical psychology), to give assistance to the Senior Psychologist—The Secretary, National Hospitals for Nervous Diseases, Queen Square, London, W.C.1 (June 30).

Assistant Lecturer in the Department of Biochemistry—The Secretary, University College, Gower Street, London, W.C.1 (July 6).

Assistant Lecturer or Lecturer (with an honours degree and preferably experience in hydraulics) in the Department of Fluid Mechanics—The Registrar, The University, Liverpool (July 6).

Demonstrator (preferably with a knowledge of plant physiology or biochemistry) in the Department of Botany—The Registrar, The University, Liverpool (July 6).

Chair of Mathematics in Fourah Bay College, Sierra Leone (University of Durham)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (July 7).

Lecturer (preferably with a special interest in statistics) in Mathematics; and a Lecturer in Inorganic Chemistry at Fourah Bay College, Sierra Leone (University of Durham)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (July 7).

Research Assistant (veterinary surgeon or graduate in microbiology) in the Department of Veterinary Pathology, for work on the pathogenesis of fowl typhoid—The Registrar, The University, Liverpool (July 7).

Assistant Lecturer or Lecturer in Astronomy—The Secretary, University College, Gower Street, London, W.C.1 (July 13).

Biometricians (with an honours degree in mathematics and some industrial training, and preferably experience in consulting work or in the analysis of experimental results) in the Agriculture Department, Wellington, New Zealand, to assist in the section which advises on the design and undertakes the analysis of research work—The High Commissioner for New Zealand, 415 Strand, London, W.C.2, quoting Ref. No. B.11/2/15 (July 17).

Lecturer/Senior Lecturer in Applied Mathematics at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, July 25).

Foundation Chair of Philosophy in the University of New South Wales, Australia—The Agent-General for New South Wales, 56 Strand, London, W.C.2 (Australia, July 31).

Senior Lecturer in Botany at Canberra University College, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (August 1).

Assistant Experimental Officer (male graduate in agriculture or agricultural botany) in the Department of Herbage Agronomy to carry out field experiments on methods of establishing leys—The Secretary, The Grassland Research Institute, Hurley, Maidenhead, Berks.

Assistant Lecturer (with special qualifications in applied mathematics) in Mathematics—The Registrar (Room 22, O.R.B.), The University, Reading.

Chemist or Biochemist, for research in the steroid field—The Director, Group for Research on the Chemical Pathology of Steroids, Jessop Hospital for Women, Sheffield 3.

Chemist (with a good honours degree in agricultural chemistry or chemistry) in the Department of Agriculture, Uganda, for research on soil fertility problems connected with tropical crop rotations, manures and fertilizers—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/9/09.

Demonstrator in Physical Chemistry—The Registrar, The University, Nottingham.

Demonstrator or Research Fellow (preferably graduate with a knowledge of aerodynamic theory and wind tunnel experiments) in Aerodynamics—The Recorder, College of Aeronautics, Cranfield, Bletchley, Bucks.

Electron Microscopist, to study fine structural changes in cells following radiation, "g" force, stress, high frequency vibration, etc.—Chairman, Department of Anatomy, Emory University, Atlanta 22, Georgia, U.S.A.

Head of the Department of Pharmacy—The Registrar, Bradford Institute of Technology, Bradford 7.

Lecturer in Electrical Engineering at Brighton Technical College, to teach to Professional Diploma and Higher National Certificate standard—The Director of Education, 54 Old Steine, Brighton.

Lecturer in Mathematics, and a Lecturer in Statistics and Mathematics—The Registrar, Bradford Institute of Technology, Bradford 7.

Lecturers in Mathematics, Physics, Biology and Biochemistry—The President, University College, P.O. Box 399, Addis Ababa, Ethiopia.

Master (with a good honours degree) to take charge of Chemistry and to teach from IVth to VIth Forms (at least to *A*-level)—The Headmaster, St. Edmund's College, Old Hall Green, Ware, Herts.

Physicist (with at least a second-class honours degree or equivalent qualification), to work in a team engaged on the basic research on powder pressing and sintering and allied processes—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting Ref. 2108/34.

Reader in the Department of Electrical Engineering—The Registrar, Royal Technical College, Salford 5, Lancs.

Research Assistant (engineering and science graduate), for research into oil fuel combustion—R. P. Fraser, Department of Chemical Engineering, Imperial College of Science and Technology, London, S.W.7.

Research Fellow (physical chemist or biochemist), for work on virus substructure in conjunction with a team studying the structure of viruses by physical methods—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1.

Senior Lecturer, and a Lecturer in the Department of Electrical Engineering—The Registrar, Royal Technical College, Salford 5, Lancs.

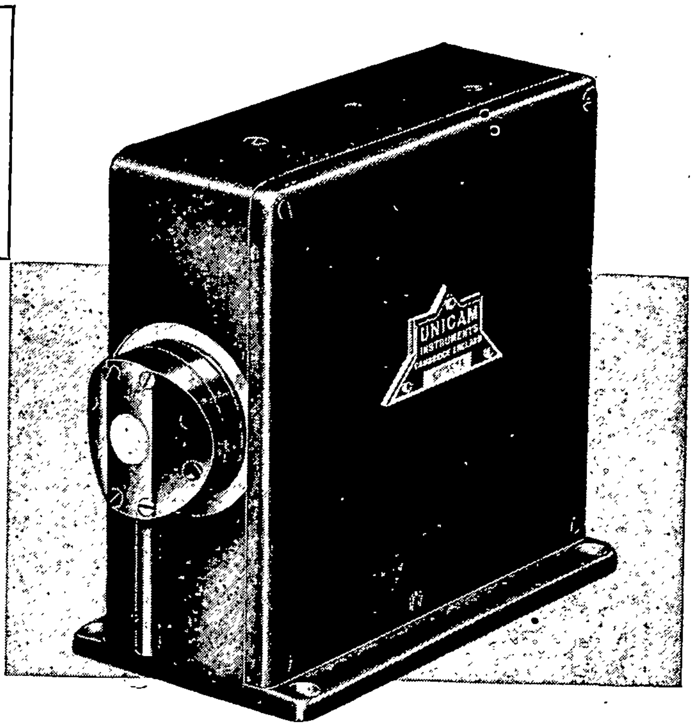
An INFRARED DETECTOR

sensitive
from
Visible
to
Microwaves



The operation of the Golay Detector is based upon the expansion of a gas of low thermal conductivity in contact with a non-selective heat absorbing membrane. The cell in which the gas (normally Xenon) is sealed has at one end a mirror membrane operating in a photoelectric amplifier system in such a way that the light intensity at the photocell varies directly with the gas expansion.

One of the major advantages of this system is a uniform sensitivity over a wide range of wavelengths. With suitable window material the Detector can be used to measure radiation intensities from visible light out to the microwave region. The adjoining table shows recommended window materials for specific wavelength regions.

The Detector can be delivered from stock with the following windows—KBr, Quartz, KRS-5, CsBr.

We shall be pleased to quote for alternative windows, for the Detector alone or for the full equipment including electronic and chopper units.

TABLE OF WINDOW MATERIALS

Material	Approximate useful wavelength limits
KBr	from visible to 26 μ—27 μ.
CsBr	„ „ „ 35 μ—40 μ.
CsI	„ „ „ 45 μ—50 μ.
Quartz (0.25 mm thick)	„ „ „ 3.5 μ and from 45-50 μ to microwaves.
*Arsenic trisulphide	„ „ „ 10 μ.
*KRS-5	„ „ „ 35 μ.

*These two salts are non-hygroscopic but introduce some energy losses.

EXPANSION OF SCIENTIFIC AND TECHNICAL EDUCATION

"ONE determinant of a nation's greatness," writes Dr. Detlev Bronk in his chairman's foreword to the eighth annual report of the U.S. National Science Foundation, "is its courage to choose between the important and the less important. A nation achieves greatness by determined devotion to the things that matter most as it sacrifices the unessential." Dr. Bronk refers particularly to forthcoming debates in the United States on expenditure on scientific teaching and research, and his words are no less applicable to continuing discussion in Britain as to expenditure on education and the balance between that expenditure and the research effort. The account of the Foundation's expanding effort in improving the quality of education in science is indeed the feature of the 1958 annual report which is of most interest to British readers. Educational structures differ widely in the two countries, but the main problems are largely similar, and experience gained in one is likely to have real value in the other, even if methods can rarely be applied without adaptation.

The background to this expansion is well outlined by Dr. A. T. Waterman in his statement as director of the Foundation. Following President Eisenhower's 'messages' of November 1957 and June 1958, particular attention was directed by the Foundation to the development of the capacity of the United States in scientific and technical research, and to its educational resources in science and engineering. Besides the increased responsibilities of the Foundation itself in the field of education, the National Defense Education Act represents a step towards improving the educational system generally ; but Dr. Waterman points out that all the measures already adopted are only a beginning. There appears to be no immediate prospect of adequate salaries for school teachers, of adequate school buildings and facilities, or of adequate facilities for recruiting sufficient competent teachers. Plans for dealing with important areas of research are still inadequate, and the urgent problem for science and engineering in the universities of the United States is to secure modern laboratories and research equipment, including rather costly equipment for the larger institutions, and to provide for larger capital research facilities to be used nationally or at regional centres. The training of more scientists also calls for extended laboratories and equipment, and maintenance and operation require expanding funds.

The problems are thus essentially the same as those with which the Advisory Council on Scientific Policy is concerned in Britain, but Dr. Waterman is not satisfied that in the United States they are faced with sufficient determination and realism. Making all allowance for the internal issues which complicate decisions, such as the relative responsibility of the Federal Government and State and local authorities for education, the clash between national policy and individual initiative and aspiration, Dr. Waterman considers that lack of realization and determination on the part of its citizens hinder scientific and educational advance in the United States. A clear conception of national objectives, how they can be achieved, and the citizen's part and responsibility in that task is a first essential, and he suggests that the Federal Government has a first responsibility to see that the problem is fully understood by the people. It must also provide direct support according to carefully devised plans and consider seriously ways and means of increasing substantially funds from other sources.

As broad objectives of national policy, Dr. Waterman puts forward the full development of individual and collective capabilities, and the identification and selection of the fields of effort which merit maximum expenditure of money and man-power. In science, the maximum emphasis should be placed upon the relatively modest needs of basic research so as to discern the possibilities of progress in technology, followed by careful choice of the fields for development that require large capital sums. Those objectives could largely be accepted as valid for Britain, though the distribution of resources and the selection of fields for development would not necessarily be similar, quite apart from any considerations of Anglo-American co-operation.

Reviewing Federal activity in the field of education, the report points out that while Congress has already increased threefold the 1959 appropriation for the Foundation's educational programme (compared with the five-fold increase recommended by the President in January 1958), the National Defense Education Act of 1958 was the first general Federal aid-to-education legislation for ninety-six years, and it re-affirmed the primary educational responsibilities of State and local communities. Apart from providing for loans to students to enable them to attend college, for awards of graduate fellowships and for State grants for vocational programmes for training technicians, under the major administrative responsibility of the Department of Health, Education and Welfare, the Act initiated a Science Information Service in the National Science Foundation to develop new and improved methods for disseminating scientific information.

Some details of the Foundation's educational activities during the year are given in the report. There are in the United States some 140,000 high-school teachers of science and mathematics, though a significant proportion are not adequately trained, and in the spring of 1958, 16,000 of them applied for admission to the summer schools which the Foundation sponsored. Of these, 6,300 teachers received support from the Foundation grants at summer schools averaging seven weeks in duration. Grants were also made to nineteen universities for similar schools in science and mathematics during the school year 1958–59, in which 925 teachers were trained, and for 1958–59 about thirty summer schools are planned. About 3,000 high-school teachers attended other 'schools' offering courses out of school hours, and for 1959–60 the number of such institutes supported by the Foundation is to be increased from 86 to about 200. The Foundation also proposes to offer about 550 fellowships for graduate teaching assistants for the summer of 1959, to enable them to pursue, full-time, their own study programmes during the summer months, and about 750 science fellowships for secondary school teachers of science and mathematics who hold bachelor's degrees to enable them to pursue a personal study programme over one to three summers.

Besides these programmes attempting to improve the qualifications of existing teachers and to shorten the time in which qualifications can be obtained, the Foundation is trying out new methods of increasing the understanding of science by young people. These are of three types. Some seek to enlist the interest in and understanding of science, mathematics and engineering by students at all levels. These include a travelling high-school science library programme, a travelling science demonstration lecture programme, particularly in such subjects as solar radiation, atomic structure, nuclear reactions and space travel (a programme which enables distinguished scientists to visit small colleges and universities for several days), a science club project and a summer training programme for secondary school students. The second type comprises a variety of teacher-training projects, and the third stresses studies of the content of science curricula in secondary schools, in which new and imaginative approaches to instruction in science have resulted from the judgment and experience of scientists and teachers, including the development of an entirely new course in physics for the high-schools.

Some of these programmes are extensions or developments of projects on which the National Science Foundation had already embarked, and parallel activities are indeed to be found in Great Britain. The Minister of Education, for example, has already recognized the need for examining our methods of teaching science and our curricula with fresh minds. The Advisory Council on Scientific Policy is known to be aware of these problems, and an important session at the Home Universities Conference last December on standards of teaching and techniques and the supervision of students in universities showed that the universities are already considering what can be done, quite apart from the implications of the forthcoming expansion. To a limited extent, the opportunities which new techniques, such as sound broadcasting and television may provide, are being explored, although there is nothing exactly parallel to a project supported by the National Science Foundation and sponsored by the American Institute of Biological Services which seeks to evaluate the effectiveness of the use of experimental colour television films in biology.

The annual report of the National Science Foundation is thus a welcome reminder of possibilities in meeting the shortage of science teachers and in expanding our output of scientists and technologists. It does more than point to possibilities which may here have been overlooked or been insufficiently examined. It sets the whole problem in its proper perspective and emphasizes the need for looking at education as a whole and for dealing with it with real determination, urgency and vision.

On that there are two points to be made. A first priority is the creation of a wide public understanding of all the issues involved; this is a task to which professional associations generally, and not those of teachers alone, should be addressing themselves. The British Association is already supporting important projects to this end, as the American Association for the Advancement of Science has done, and some of the professional organizations are already taking an increasing interest in the training of those entering their own professions. It should not be a difficult step from such work to participation in the task of developing a wider public understanding of the implications of education generally.

Secondly, while the American effort in the improvement of the quality of scientific and technical education and the expansion of its scale, vastly exceeds the present effort in Britain, it is important to remember that mere expansion itself is not enough. Expenditure on education in Britain must be appropriate to national needs and resources, and conditioned by them and by our ideals and traditions, not by those of other countries, however closely associated. Moreover, it is at least as important to see that the most effective use is made of expenditure as to see that the expenditure is adequate. As in research, there is real danger that full use will not be made of existing facilities and expenditure through failure to provide the essential equipment, aids and supporting technicians.

In this connexion, the discussion at the Home Universities Conference* is suggestive. Prof. R. J. Pumphrey challenged the validity of the existing lecture system, and he pleaded for wider use of libraries and reading and the more generous provision of such facilities; and although others, like Prof. J. T. Brindoff, did not agree that the university lecture had outlived its usefulness, there was strong support for his plea for expansion of the university library, though it was also pointed out that the student has yet to learn the art of reading in a library. It was clear enough that fresh thought is already being given to existing methods and techniques, and that a comparatively minor increase of expenditure at particular points would enhance the present efficiency of both teaching and research. Indeed, Prof. B. Bleaney showed that there is very real danger so far as physics is concerned, unless larger Treasury grants are forthcoming. It was no less apparent, however, that if in the expansion of education in Britain already proceeding the full benefits are to accrue, to the individual and to the community, there must be clear conceptions as to the exact functions of our educational institutions, the purposes they are to serve and their relations to one another. These must be in harmony and the resources placed at their disposal appropriate to the function to be served, if we are to avoid either waste of effort and resources or to achieve such a standard of education and supply of trained men and women as Britain needs to use the opportunities that confront us in this age of rapid technological change.

JOHN DALTON

The Biographical Approach to John Dalton

By Frank Greenaway. *Memoirs and Proceedings of the Manchester Literary and Philosophical Society,* Vol. 100, 1958–59. Pp. vi+98+11 plates. (Manchester: Manchester Literary and Philosophical Society, 1958.) 21*s*.

THE hundredth volume of the *Memoirs and Proceedings* of the Manchester Literary and Philosophical Society consists of a memoir by Frank Greenaway on "The Biographical Approach to John Dalton". It deals with the older biographies written by Henry, Angus Smith, Lonsdale, and Roscoe, and also gives, for the first time, a connected account of the newer work of Roscoe and Harden, Meldrum, and Gee, Coward, and Harden, as well as of some later publications.

This essay is very interesting, and a good deal of painstaking work has evidently gone into it; but it fails, in my opinion, to do justice to Dalton. It includes too much which is irrelevant and omits too much which is essential to a proper understanding of the place of Dalton in the history of chemistry. Some justification for the last statement can first be given.

It has often been said that before the enunciation of his atomic theory Dalton did little or nothing of importance. In fact, Dalton had published work on the theory of mixed gases and the state of water vapour in the atmosphere, on the conduction of heat in liquids, on the vapour pressure of water, and on the expansion of gases by heat; and if he had done nothing else he did, and would still, rank high. Mr. Greenaway says that in his early meteorological work, "Dalton slipped into a groove of study which led him to a position he never fully understood". It led him to the discoveries mentioned above and to ideas which, unless we knew that they were first published by Dalton and were initially received with incredulity, we might think are self-evident.

It has also often been said that after the publication of his atomic theory Dalton did no work of importance; he was, says Mr. Greenaway, "an anachronism". Yet some of his later work, such as that on the combustion of hydrocarbons, on the vapour density of ether, and on the isomeride of ethylene in coal gas is really important.

Another old error which is repeated is that Dalton was a coarse and inaccurate experimenter. His work on gas analysis, which (as everybody who has done any knows) is difficult, is quite exceptionally good, and although Mr. Greenaway dismisses the third volume (II, ii) of the "New System" in a word or two as of no interest, it contains some surprisingly accurate work on the equivalents of metals which has been pointed out by Trengrove. A mention of Dalton's "undeserved reputation as a chemist" is unnecessarily severe on the judgment of contemporary chemists.

Dalton's early work on the aurora is given but it is not mentioned that Faraday later proposed the same theory without naming Dalton; no reference is made to Dalton's later experiments on the composition of the higher atmosphere and his explanation of the results, quite recently proposed again as original.

Dalton did not read many books, but the suggestion that "his often-quoted claim to be independent of them may well have been an impromptu attempt to conceal a feeling of inferiority in the face of those who were more accustomed to them", is one of those random guesses which sometimes pass for biography. One of the books Dalton read in his early period is Bishop Watson's "Essays", on which F. Sherwood Taylor's over-clever statement that it could have been written in a year and "smells more of the lamp than the laboratory" is quoted. This book (in five volumes) records Watson's visits to mines and factories extending over many years, and contains some extensive research of his own which is known to physical chemists. Watson's work on gunpowder is also well known. This sort of history simply will not do.

Dalton's mentality seems to have been relatively straightforward as compared with personalities such as Newton, Priestley and Lavoisier. Mr. Greenaway gives an anecdote (p. 7) about Granville (who is otherwise little known) revisiting Dalton in old age and finding him busy trying to loosen a stuck glass stopper. Dalton gently resisted an attempt to assist and finally released the stopper himself. Then, although obviously busy, he had a few courteous words with his unrecognized visitor and got rid of him. This was typical of Dalton, but all Mr. Greenaway gets out of it is that "there was a little glow still in the grey ash of the man".

The section on the origin of Dalton's atomic theory is one of the best, but it too fails to bring out some important matters. Mr. Greenaway thinks that earlier writers have been inconsistent in saying that the origin goes back to Newton while Dalton used a theory of heat different from Newton's. A little might have been said about Newton's own use of this theory of heat, and why Dalton adopted a different one. The influence of Lavoisier's "Traité" could have been considered, and particularly how Dalton's criticism of an erroneous theory of mixed gases contained in it was related to the development of his own theory.

The final section of the essay is a rather confused assembly of some recent pronouncements on the philosophy of making discoveries; it is not easily understood.

If I were asked to hazard an opinion I would say that Dalton has been too much for many of his biographers; the most successful of these was probably Roscoe, largely because he was a chemist, had read Dalton carefully, and had a good knowledge of the state of physics and chemistry when Dalton began his work. The same qualifications are needed in a future biographer of Dalton, who will have the advantage of new knowledge which has accumulated since Roscoe wrote.

Mr. Greenaway's essay gives a good if incomplete summary of this new knowledge, and he has added a few new morsels—no mean achievement in the field, since much of the material has been lost. He deserves thanks for what he has done. J. R. PARTINGTON

APPLIED ANALYSIS IN THE U.S.S.R.

Approximate Methods of Higher Analysis

By L. V. Kantorovich and V. I. Krylov. Translated from the Russian by Curtis D. Benster. Pp. xv+681. (Groningen: P. Noordhoff, Ltd., 1958.) n.p.

THE first edition of this book appeared in 1936, as "Methods for the Approximate Solution of Partial Differential Equations"; it dealt with boundary value problems for linear equations. The title was changed to the present one for the second edition (1941), on the inclusion of an extended treatment of conformal mapping, and an account of the numerical solution of integral equations. The present translation is from the 1952 edition,, which does not differ greatly from the earlier editions: the authors promise a complete revision which shall take account of the substantial progress made since 1941, when no doubt the use of linear operators and function spaces, for example, will find a place. In the interim, a translation is most welcome, since the book as it stands is probably alone in its class, yet for linguistic reasons many of us have been debarred from immediate knowledge of its richness of content. In spite of an increasing flow of translated books and periodicals, it is not easy to acquire a full insight into the rapid growth of Soviet mathematics, though F. J. Weyl, writing from the U.S. Office of Naval Research, measures the will to do so by his remark: "It is a unique distinction of the mathematical community to have never been taken in by the myth, now generally shattered, that Russian science merely followed the lead of the West—at a respectful distance".

The book in each of its main sections exhibits the intention of pressing the processes of pure mathematics beyond the domain of form and theory to the region of numerical calculation, to numerical approximations accompanied by estimation of error. Methods are illustrated by examples from various fields of applied mathematics, carried out to detailed numerical conclusions with evaluations of bounds to errors. The first section deals with solutions of Laplace's equation by infinite series, including Fourier series, with paragraphs on methods of accelerating the convergence. The second section discusses numerical methods for solving integral equations of Fredholm's type, with some emphasis on the 1930 method of N. M. Krylov and N. N. Bogoliubov, illustrated by solving the Dirichlet problem for an elliptic boundary. In the third section, the method of nets, which replaces a partial differential equation by a set of finite difference equations, is expounded with attention to the convergence of the process and the estimation of error. Rather more advanced theory begins in the fourth section, which studies variational methods: the Rayleigh-Ritz method, first fully elucidated by N. M. Krylov, and the related but somewhat simpler and more general method of Galerkin, are fully explained and exemplified. The fifth and sixth sections form a compact treatise of 250 pages on the theory and applications of conformal mapping; the reader is supposed to know the elementary ideas as far as Riemann's theorem on the existence of a conformal mapping between two simply connected domains. The boundary-value problems of Dirichlet and Neumann, and for the biharmonic function, receive thorough treatment. There are numerous examples, though, for the biharmonic problem, the reader is naturally referred to the many and varied applications of the method made by Muskhelishvili in his excellent book on elasticity. It may be noted that Muskhelishvili refers to Kantorovich and Krylov as a classic work on the application of complex variable methods, and the two books resemble one another closely in spirit and in technique. The final section gives Schwarz's method of solving Dirichlet's problem for a complicated domain by combining solutions for simpler domains: the method is illustrated by the complete solution for an L-shaped domain.

As a compendium of methods available in 1940, and as an instance of what can be done by skilfully combining general theory with numerical analysis, this is a noteworthy volume. It should be interesting to see how future revisions are modified by the increasing dominance of the automatic computer. The translation, by C. R. Benster, is fluent: the bibliography unfortunately makes no serious attempt to include non-Russian material. T. A. A. BROADBENT

THE THEORY OF PRACTICE

Planning of Experiments

By Dr. D. R. Cox. (Wiley Publication in Applied Statistics.) Pp. vii+308. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1958.) 60*s*. net.

DR. D. R. COX succeeds well in his aim of writing an introduction to modern thought on the design of experiments free from the statistical and mathematical technicalities that often discourage the experimental scientist from study of a subject so inportant to his own work. He says much about the nature of computations required in the analysis of experimental results without presenting one analysis of variance table. He displays a wide range of standard experimental designs, and discusses their uses, while saying little about how to construct them or about mathematical theorems relating to their existence.

Although an increasing number of scientists has sufficient knowledge of statistical practice to learn about experimental design more intensively than this approach permits, undoubtedly many others will profit from it. The book could be an admirable introduction to statistical ideas for a biological or industrial scientist; from it he would learn little about the standard procedures of statistical analysis, such as are to be found in most elementary text-books, but he would acquire something of greater practical value, an appreciation of the manner in which the design of an experiment affects the precision of the results and the efficiency with which the experimenter's time and resources are used.

Dr. Cox's book is far more than an introductory text. With the exception of Davies, probably no writer on design has given comparable attention to questions of general planning, such as the choice of treatments and levels for testing, of experimental units, and of measurements. Anyone concerned with experimental statistics can benefit from studying, for instance, the sections on types of factors and interactions and the choice of factors for inclusion in an experiment. An excellent and varied collection of examples will make the book also of value to the teacher.

The only serious blemish is the conversion of 6.25 dollars into a British price of 60 shillings.

D. J. FINNEY

Bertil Hanström

Zoological Papers in honour of his sixty-fifth Birthday, November 20th, 1956. Edited by Karl Georg Wingstrand. Pp. 312. (Lund: Zoological Institute, 1956.) 50 Sw. Kr.

SCRUTINY of these papers soon reveals that they mark more than a formal occasion. In offering them to Prof. Bertil Hanström, the contributors have taken obvious pleasure in expressing their gratitude to him " . . . as a teacher and leader of the Zoological Institute in Lund".

Prof. Hanström's first paper was published in 1915, and it dealt with the birds of the island of Öland. While his subsequent work has been mainly concerned with nervous systems, particularly with neurosecretion, Hanström still finds time for field studies. It is thus not surprising that Lund is now an important centre for systematic, zoogeographical and ecological work.

Hanström's interests are clearly reflected in this series of papers. As might be expected, there are several papers on neural and neurosecretory systems (concerning insects, chilopods, crustaceans, cephalopods and the toad, *Bufo bufo*). Others deal with the systematics and relationships of crustaceans, ecology and cytology. The range of these papers shows clearly that zöology is in a flourishing state at Lund.

The contributions are nicely produced and bound, the design for the cover being particularly appropriate.

Diagnostic Performance Tests

A Manual for Use with Adults. By Boris Semeonoff and Eric Trist. Pp. xv+176+4 plates. (London: Tavistock Publications, 1958.) 32*s*. net.

AS is well known, intelligence tests were evolved in order to detect and assess educationally subnormal schoolchildren. Their intention was to sample mental growth in its various aspects and to provide reliable standards of performance in relation to age. By and large they succeeded admirably. In the case of adults, on the other hand, mental testing has proved altogether less satisfactory. Although a wide variety of tests purporting to measure adult intelligence exists, it is seldom clear precisely what is being measured or how much confidence can be placed in the results. In consequence, the use of intelligence tests with adults has been viewed—in Britain at least—with understandable reserve.

The methods of testing intelligence described in this book have an unusual history. In 1940, Mr. Trist was concerned to develop some tests of intellectual deterioration due to injury or disease of the brain. In the light of the work of Goldstein and others, it had become plain that such deterioration is particularly liable to show itself in performances involving abstraction, spatial analysis and sequential learning. Mr. Trist was therefore led to devise a small battery of tests well adapted to reveal defects in these fields. But it soon became clear not only that extensive control data were necessary but that the techniques might have important application to the assessment of healthy individuals. At this point Dr. Semeonoff entered the picture and was able to carry the work very much further. Indeed, the present book is very largely the outcome of his prolonged and patient endeavour.

The performance tests reported here have the advantage first, that they make little demand upon linguistic sophistication; and secondly, that they permit some evaluation of important aspects of personality. Indeed, the emphasis throughout is upon assessment of the individual as a whole rather than upon some arbitrary dimension of intellect or temperament. In consequence, these tests may be expected to find application not only in clinical psychology but in any field of personnel selection in which considerations of temperament are relevant.

This battery of tests is perhaps the first to be evolved in part at least on a neurological basis. If it be conceded that the brain has at any rate something to do with intelligence, this would seem a notable—if belated—achievement.

O. L. Zangwill

A Study of Blackbirds

By Dr. D. W. Snow. Pp. 192. (London: George Allen and Unwin, Ltd., 1958.) 21*s*. net.

BEFORE the natural history of a wild species can be understood it must be studied from more than one point of view—only when behaviour, ecology, systematic position and other aspects of its biology are inter-related can a full picture be obtained. This book describes a study in which much progress has been made in this direction. Based on four years work in the neighbourhood of the Botanic Garden, Oxford, it presents intimate details of the history of a small community of blackbirds, many of which were colour-ringed. Although written in non-technical language (much of the material has also been published in scientific journals), the author places his observations against a wide background of biological principles, and thus provides material both for the general ornithologist and for professional biologists.

As well as descriptions of the life-history, displays and vocalizations of the blackbird, many interesting facts which could have come only from a close study of colour-ringed birds are presented—for example, the pairs which are sometimes formed in winter are only temporary affairs; and male and female feed different individual young after the brood has left the nest.

Perhaps the most interesting chapters are those which deal with population problems. In particular, a contrast is drawn between garden and woodland populations. The former are dense, with a high breeding success, and produce an excess of young birds which do not disperse before settling. Under these conditions, territorial behaviour limits breeding density. Woodland, on the other hand, is sparsely populated, and breeding success is low; population density is probably controlled largely by survival in the preceding winter.

R. A. Hinde

Proceedings of a Symposium on Insect and Food-plant

Wageningen, May 27–29, 1957, under the auspices of the Comité Européen de Zoologie Agricole (C.E.Z.A.) and the Agricultural University, Wageningen. Pp. 118. (Wageningen: Landbouwhoogeschool Laboratorium voor Entomologie, Berg 37, 1958.) 5 florins.

SYMPOSIA are becoming increasingly used as a means of communication between scientists; subsequent publication of the reviews and discussions often go far to help the research worker to keep abreast of the latest ideas and results of others. According to the preface of the proceedings of this symposium, the organizers had hoped to obtain during the discussions "a synthetic view of the whole complex of insect – host-plant interactions". Although this aim was, unfortunately, not achieved, the articles are a useful survey of recent work which every agricultural entomologist will want to have by him.

The symposium was held under the auspices of the Comité Européen de Zoologie Agricole and the Agricultural University, Wageningen, under the presidency of Prof. B. Trouvelot. The contributors came from six different European countries and one came from Canada; their articles are in English, French and German, most of which have a summary in one of these languages. Ten of the fourteen articles have already appeared in Vol. 1 of the new journal, *Entomologia experimentalis et applicata* (*Nature*, 181, 1040; 1958).

The emphasis of the symposium was on food-plant selection and the resistance of host-plants to phytophagous insects. Six articles deal particularly with the Colorado potato beetle which has received much attention from European workers in whose countries it is a serious pest; work on host-plant resistance to the beetle among the Solanaceae and on the behaviour of the larva is reviewed. Two papers are concerned with aphids, and one, by a botanist, reviews the related subject of phloem sieve tube sap. One contributor discusses the significance of the salivary secretions of 'plant-sucking' Hemiptera, and another, in a brief summary (in German), deals with his work on the choice of food by certain lepidopterous pests. Two articles on the potato-root eel-worm are included on the grounds that the problems of the nematologist are similar to those of the agricultural entomologist, but an article on the dietetics of a blowfly appears to be somewhat out of place. C. J. BANKS

Instrument Encyclopedia

Compiled by Edward W. Battey. Pp. xix+292. (London: The Herbert Publishing Co., Ltd.) 63*s*. net.

THE purpose of this book is defined in the preface as follows: " . . . to provide a concise reference to the materials and equipment used and produced in the Instrument Industry . . . and to define the terms employed and required by instrument users in every industry. The Encyclopedia is not in any sense intended as a text-book. . . ." The compiler has realized these aims remarkably well.

The book starts with a detailed index and a short but well-planned encyclopædic section explaining meanings of technical terms. It includes some of the near slang expressions which have found general use, and references are given, where appropriate, to British Standards specifications. The remainder of the book consists of alphabetical lists of manufacturers, complete with their addresses and telephone numbers, a list of overseas agents, a catalogue of trade names and an extremely full buyers' guide. This last section is the largest and perhaps the most useful. It permits one to discover the manufacturers of any specific instrument or component, and is divided into eight sections (Laboratory, Medical and Research; Optical and Ophthalmic; Electronic and Nucleonic; Electrical; Engineering; Automation and Process Control; Accessories and Components; Nautical, Aeronautical and Surveying.)

In order to make some kind of assessment of the completeness of the information a number of 'spot tests' have been applied, and the "Encyclopedia" survived most of them with flying colours. It defeated many attempts to think of lesser known firms or instruments which, though not included, should legitimately come within its scope.

The only real criticism to be made is of the title. One usually thinks of an encyclopædia as a collection of explanatory information: the actual encyclopædic section of this book is only 28 pages long and perhaps it would have been wiser to choose a title more in keeping with the remaining 264 pages. However, it will undoubtedly prove a most valuable work of reference, particularly for those needing to use apparatus and instruments not closely allied to their own field of work. C. A. TAYLOR

Dictionary of Physics

Compiled and Edited by H. J. Gray. Pp. x+544. (London and New York: Longmans, Green and Co., Ltd., 1958.) 84*s*. net.

THERE are obvious difficulties in reviewing a dictionary since the reviewer can scarcely be expected to read it from cover to cover. But 'spot' checks in several different branches of physics showed very few weaknesses; only a few items sought (synchrocyclotron, photo multiplier, Fermi surface) were not found. In general, the definitions are clear and concise, and references are given for follow-up reading. Perhaps the policy of giving only the earliest references is unwise, even if historically they are the most important.

A few mistakes were found: the diagram of the spherometer is described as that of the planimeter; the last sentence of the entry for Laue is wrong; a sign convention in optics is called the 'real position' convention. But on the whole the number of such mistakes appears to be small. The reviewer is glad to note that the dictionary insists on the correct spelling for Abbe (not Abbé) and is not caught out by Kirchhoff; it also ascribes Bragg's law to the correct Bragg.

The dictionary may thus be described as an extremely useful work. It is obviously not perfect; but it will form a handy work of reference for any physicist. H. LIPSON

Zirconium

By Dr. G. L. Miller. Second edition. (Metallurgy of the Rarer Metals, No. 2.) Pp. xxi + 548. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1957.) 70*s*.

FIRST published in 1954, this important work of reference on the manufacture and properties of zirconium has been considerably re-written and enlarged with an increase in the number of pages from 374 to 535. The price of the book has also increased from 45*s*. to 70*s*.

Dr. Miller has made some reconstruction to the text and the arrangement of the matter and has taken advantage of relaxation of classified information in various directions, and added a considerable amount of new data.

The principal additions are in the description of the Kroll process, in the description of the thermal properties and the tensile properties of zirconium, and in the description of the mechanical properties of certain zirconium alloys. The section on corrosion of zirconium by liquid metals has been expanded substantially and the number of pages devoted to melting practices has been doubled. There have also been additions in connexion with the fabrication processes for zirconium and in the description of the nitrides, carbides, borides and silicides.

This book represents the best compilation of information on this subject at the present time. W. D. JONES

THE AMERICAN COLLEGE AND THE EDUCATED LIFE*

By Dr. DOUGLAS M. KNIGHT
President of Lawrence College, Appleton, Wisconsin

THE Rockefeller Institute lends and can lend unique distinction to our image of the educated man; but that image could not properly exist without a widespread and deeply rooted sense of what goes into his creation, encouragement, and nurture. The community of graduate scholars at its finest is not possible unless there stands prior to it the community of those who may some day be scholars.

The mandate to create a climate for liberal learning has been alive in most undergraduate colleges since their beginning. Their frontier setting, their financial struggles, at times their narrow sectarianism—none of these things should blind us to the fact that their very foundation in the midst of so much uncertainty was a major act of faith, and faith in the same qualities of inquiry, judgment, commitment which two hundred years earlier had led to the founding of the country's oldest college. Fortunately for American intellectual development as a nation, many of the nineteenth-century undergraduate colleges have remained true to a version, at least, of their original duty. To say so implies no criticism of those which have become world universities during the last century, but a Harvard, a Yale (or a Rockefeller Institute, for that matter) owes much of its opportunity for great achievement to a group of small, less privileged institutions which in the last hundred years have developed the art, the science, and the community of distinguished undergraduate education. The context of the houses at Harvard and the residential colleges at Yale is not merely the tradition of Oxford and Cambridge; it is equally the tradition of the American college.

I sometimes hear it said that in the harassed world of to-day and to-morrow the undergraduate college will have a precarious and uncertain time; those who make the remark do not know the history of these colleges, which in a sense has always been precarious; nor do they remember that any great cause must have elements of the precarious and uncertain about it. The history of the American college at its best is a history of steadily increasing strength, of increase in intellectual range and sophistication without the sacrifice of coherence, of increase in duty to the country without the sacrifice of local obligation.

The gravest danger in the years ahead (and if it is a danger to the colleges it will be an equal menace to the great communities of graduate study) is not the danger of financial bankruptcy or depleted faculty. The greatest danger will come from the more subtle and more pervasive issues which involve our whole society—the steady shift towards a national uniformity in culture, the equally steady diffusion of residential communities, the explosive developments of knowledge which often outdate our perception before we have time to master it. These shifts will stand behind the real crises of undergraduate education in the years just ahead of us. These are more critical issues for the college than for the university, simply because the college depends for its life on the real and daily community of those who learn, and equally on the orderly assimilation of the major disciplines and the major modes of understanding. A great university to-day often assumes (for better or worse) that it is not one community but many; it assumes equally that it has a primary obligation to the growing edge of knowledge in a hundred fields, rather than to the full assimilation of knowledge either within these fields or between them. Such assumptions would be fatal for a college; it must face instead a question in some ways more complex than the university question. It must maintain the community of learning both in idea and in fact; it must affirm and sustain the steady growth of knowledge, while equally it must maintain the coherence of knowledge. Both in its sense of community and its approach to learning, it must avoid the cold death of being academically outdated on one hand, or the fiery end of being intellectually fragmented and shattered on the other. Unless this balance of forces can be sustained, the distinguished liberal colleges will obviously suffer in the next twenty-five years; and if they do fail in their attempt at coherence, the damage to the university and the graduate research centre will be greater than most of us realize.

The hope and destiny of the learned life cannot be confined to one type of institution, or one advanced level of performance, no matter how superb. The scholar who cannot depend upon a climate of respect in his society will not long be able to guarantee his scholarship: and since the live interchange between the scholarly life and the whole life of society occurs nowhere else so effectively as in the undergraduate years, it may not be totally arrogant to say that the future of the Rockefeller Institute rests partially in the power of a hundred liberal colleges not only to provide graduate fellows but also to maintain the climate of learning in the United States—even for and in those who themselves will never be learned men or women.

If this is so, however, then any college of stature is faced with a triple responsibility: first, for the education of those who are destined to be scholars; secondly, to the sense of coherence in knowledge without which true learning soon becomes impossible; and thirdly, to the national climate of respect for learning which must constantly increase if the learned life is to keep pace with the terrifying growth of American society. How are these things being done, and how are they to be done in the years ahead?

Two chief means are available to the college: the first grows from a formal pattern of study, the second from the living fact of an academic community. I assume that there is no uniquely effective curriculum, and no perfect community. If we look at the ends of formal education rather than its means, however, we do find a certain uniqueness of purpose in the liberal college. It assumes above all that the great traditions of knowledge and its emergent patterns have much to do with one another; that the study of Plato, for example, and mathematical theory of government, and contemporary nationalism in India may have something crucial in common. If it is to be worth anything, this sense of continuity must look with an equal eye on the genuinely new and the permanently valid; it must represent the true and persistent relationship of many minds at many times, while it maintains its final allegiance and its deepest reverence for the timeless moment of discovery which flames only in the individual mind.

---

* Substance of an address delivered on May 21 at the Rockefeller Institute Convocation for Conferring of Degrees and Dedication of New Buildings (see also *Nature*, 183, 1629; 1959).

To say this is, of course, to imply that the curriculum of the liberal college cannot be regarded as an end in itself; whatever its formal content, whatever the means it uses to guarantee the continuum of knowledge, a course of study has its meaning only if it assumes life in the individual; it is the single person who is the true unit of education—not always a person alone, but still an individual, no matter how many times he is multiplied in his community. The great curse of size and mass in education is that they blind us to the end, and lead us instead to talk endlessly about the process. The process of education is no substitute for the educated man; in a sense the greatest responsibility of liberal education is to keep its process simple enough so that the event of true education can still occur.

If this event of education involves the individual, it also involves something very special about the individual, that is, his power to create. It is a great pity that the nineteenth-century encouraged its artists to pre-empt the language and idea of creativity; for there is no difference except one of mode between true insight about the order of protein molecules and that true insight of the poet which James Joyce describes as "his own rare thoughts, a chemistry of stars". There is no difference, except one of degree, between the subtle and distinguished perception which adult intellectuals are capable of and the first fumbling recognition by a child that the black lines on a page somehow represent reality.

In all these cases the creative mind is proving itself, alive in the individual and working with the continuum of knowledge, and it is actually this living triad of individual, creative insight and tradition of knowledge that makes the liberal college a major force in the intellectual life of our time. Any one of the three, or any two, would fail to provide that explosive encounter with the intellectual life which is the hallmark of true education as opposed to dead learning or technical discipline.

This encounter in turn both creates and is created by a particular kind of community. Historically, of course, the undergraduate college had about it the inevitable and simple order of Plato's academy (often, alas, without Plato); but the thrust of our society has put upon it a duty not imagined a century ago. As the great cities have sucked in millions of people, and then flung them out again to spawn in suburbia; as transportation has made the means of movement easy and the ends more and more obscure; as migration has become the norm of social life and not just a function of the frontier—as all these things have taken place, we have found ourselves confronting, not the regional social order that sustained us a century ago, but a national and indeed supra-national order within which we must somehow find a path. Regional order gave firm, even if narrow, support to the individual; but our struggling world order is a threat instead. It forces upon each of us the necessity to define ourselves, to establish our powers and our commitments, and then to use our talents in the service of a society that does not yet exist. We must realize that to-day we shall not find encouragement toward intellectual excellence anywhere unless we find it in academic community. Where once we could share the responsibility with many other aspects of society now we must carry it ourselves in the undergraduate colleges and the great graduate centres of learning.

As a result we have substituted in education a new frontier for the old, a frontier of the mind to replace our old frontier of physical expansion. To put the matter another way, where colleges and universities once reflected their culture, they must now create, establish and confirm it. As our society has cast off all sense of its own coherence, we have assumed the burden of creating coherence again, and often in the face of scorn or even angry opposition. The intellectual obligation of the college is equally in our future a moral and social obligation.

This obligation will be met in many ways, of course, but above all through the unique power of the undergraduate college to bring together qualities of mind and person which are often kept apart by the rest of our society. I shall mention only three of these complex qualities, and I shall represent them by a pair of what I might call 'related opposites': first, knowledge and immediate experience; secondly, tolerance and commitment; thirdly, individuality and community. In each case one half of the equation—knowledge, or tolerance, or individuality—is commonly regarded by our society as somehow less significant than the other half—immediate experience, or commitment, or communal life. It is the insistent claim of the best education, however, that we cannot participate in the immediacies, the commitments, the communities of our world until we understand them; but it is our equal claim, of course, that we fail just as badly if we give our allegiance only to a passion for abstract knowledge, only to a tolerant but therefore detached appraisal of human convictions, only to the existence of the individual and not to his relationships. The educated life expresses itself above all in a victory over these polar attitudes; it sees that wisdom can come only from the fusion (not just the co-existence) of learning and experience; it sees that responsible society can only be based on the interaction of single life and common purpose; it sees that neither wisdom nor society can long survive unless we give our equal allegiance to our own final convictions and to our respect for the convictions of others. It is the power and the duty of the best education to show that these 'related opposites' are essential to one another if the life of the mind is to flourish, and equally if the life of the community is to be possible.

I can put our responsibility best, perhaps, by saying that though these disparate human qualities need to be brought to a common life in every aspect of our society, it is only the undergraduate college, with all its pedantries and all its social follies, that can take full advantage for this purpose of a discipline of study, an intimate community, and a uniquely formative period in life. Our most singular institutions and traditions—our faculty determination to give all the wrong issues the most heated discussion, our student obsession with freedom and fumbling at responsibility, our trustee rule which combines amateurism so curiously with final control—all these things which are the material of vitriolic novels are really not the base for satire at all, but the base instead of a way of life and a definition of the mind. Without faculty independence, student freedom, or trustee non-professionalism the need to reconcile opposing attitudes and judgments would never arise, and the real nature of a democratic society would never become integral to the college. We would then be machines devoted to instruction ; instead it is our pride that we are living institutions devoted to education.

From the struggle, the diversity of judgment which are the heart of the liberal college we derive, not only the organic nature of the place but also its power to foster creative life and a sense of community. Neither of these central human concerns can exist except in a setting of freedom on one hand, and the desire to make order out of freedom on the other. Mere freedom leads us to chaos ; mere order leads us to decay. The life of the mind, and the life of true community move constantly between the two extremes, creating an order, throwing it away in the profound conviction that a better order can be found, recognizing that neither freedom nor order can be allowed to exist without the other. The philosophical and indeed theological base of all valid education consists in this perhaps ; a firm enough faith in the final values so that we can endure all kinds of darkness along the way, but a recognition that without the darkness we shall never grow in wisdom or community at all.

One of the most tragic aspects of our 'public culture' at the moment is precisely its fear of this creative darkness. We are conscious enough of the other kinds of darkness, those that lurk always at the edge of foreign policy, stare out of a mental hospital or up from the sidewalks of a slum. The darkness of unknowing, however, makes inner demands on us which we prefer to ignore or to escape ; our pride will not accept the dark humility of ignorance, and we forget that it is the only prelude to knowledge. We are willing as a society to repeat the most trivial newsprint version of reality rather than puncture with a question our own pretences at understanding.

In the face of so much bogus knowledge and so little real wisdom it is our place in the liberal colleges to maintain above all that the educated man is the man who will move ahead of his learning, not the man who hides behind it. This man, whom, we hope, we have some share in creating, lives out again and again the central paradox of the Hebrew-Christian tradition. He saves his life by losing it ; he risks his security by giving himself to a new idea, an untested theorem, a change of heart. He takes the chance of being wrong, in the faith that the only unforgiven sin is the lack of enough courage to take that chance. Every true community, and every living idea, are the results of just such courage ; and it is the central task of the liberal college to foster it, develop it, and make certain that it thrives in our society.

If I am at all accurate in this estimate of the best undergraduate education furthermore, I have also been describing the major responsibility of the Rockefeller Institute. The setting is different, the measurable task is more complex in certain ways ; but its twin bases are the creative intellect and the living community. More is expected than the advancement of knowledge, more than the interaction of the great scientific disciplines. When the first graduate Fellow was added to the community of scholars at the Institute, two new responsibilities were assumed : first, for the continuing life of the mind as something shared equally by scholar and pupil ; and secondly, for a public image of academic achievement as inseparable from the worthy ends of society at large. The Institute is an instrument of public policy as well as private research ; it embodies a way of living as well as a way of knowing.

There have been times in Western society when this way of living (the way of the best undergraduate colleges, and the strongest graduate centres) was not as important as it is to-day, and as it will be in the next half-century. It is a commonplace, but a crucial one, to point out that we are in the midst of a world revolution. Not quite so taken for granted, however, is the fact that this revolution involves every aspect of our internal as well as our external life ; and recognized scarcely at all is the fact that only the awareness and conscience of educated men can give us any hope of turning this revolution to creative ends rather than destructive ones.

The truth of the matter, however, confronts us wherever we turn. The tragic recent tangles over national security, for example, almost succeeded in destroying the tradition of responsible dissent. For a year or two many of us were faced with the specious choice between dictated conformity and scorned or discredited independence. We forgot that our political tradition demanded of us loyalty *and* freedom, not loyalty *or* freedom ; and in forgetting this we ignored the first mandate of the educated life, that we learn to live with the painful complexity of the truth: and we have made the same error in our social order, of course ; we tend to assume far too easily that our social hope and purpose are tied to our progress from group to group ; the conflicts which we allow are the thoughtless conflicts of one conformity with another, rather than the thoughtful and productive conflict between individuals and their social order.

Those of us in the academic life are no more exempt from these conformities than our neighbours in industry or government. We have our own clichés, of course, but too commonly we are their victims rather than their masters : and this is true not only if we scrutinize our participation in the social structures of our time but also if we look honestly at our own professional commitments. We assume far too easily that the truth has a departmental structure to it, and as a result we run the constant risk of scattering and dispersing the creative centre of knowledge, which lies primarily not in learned information but in learned interpretation, not in the fragmenting of reality but in its understanding. Here again, learned insight means little until it becomes educated insight, until its real purpose is the mastery of what Yeats described as "the bitter fury of complexity".

The most obvious and insistent demand on educated insight to-day comes, as all of us know, from our emerging international relationships. Here we face in its clearest public form the question which privately animates every true scholar, student, citizen ; how I am to keep my identity, my own sense of significance, while I do proper justice to the identity of others ? It is this failure as a nation quite to believe in the identity of others that has caused some of our major difficulties in the last fifteen years ; and we shall solve them only if we bring to the task of creating foreign policy the most aware and charitable insights of our best-educated minds.

All these areas in which policy and performance must grow creatively are aspects of that central revolution of our time which is a revolution in value. The struggles of a hundred societies to-day are dedicated, not to the simple overthrow of everything that has been believed in the great cultural traditions, but to the radical reassessment of every basic conviction about the nature, purpose, and proper conduct of human life. If we try to pretend that anything less than this is demanded of us by our time, then we have not even begun to act like educated people. We must affirm in the boldest way that the demands of the future are demands above all upon the mind and spirit, and that they can be met only by the deepest efforts of which the educated mind and the learned heart are capable.

THE ROLE OF THE SCHOLAR IN SOCIETY

A SYMPOSIUM under this title was held in Tunis during April 13–18. There were twenty-five invited participants, drawn from fourteen different countries; the study group meeting was organized by the Committee on Science and Freedom, of which the chairman is Prof. Michael Polanyi. The meeting was one of a series of international seminars under the general title "Tradition and Change—Problems of Progress," financed by a special grant from the Ford Foundation to the Congress for Cultural Freedom. This is an international cultural organization with headquarters in Paris, which finances the activities of the Committee on Science and Freedom.

The meeting in Tunis was concerned with the special problems of new (or newly expanded) university institutions in the rapidly developing regions of Africa and Asia, including the Arab countries of the Middle East, and in particular, with the proper relationship between these universities and the society which they serve. Tunisia is a rapidly developing African country which is planning to establish a new university, and a gratifying feature was the interest shown by the Tunisian Government, coupled with the active participation of the Tunisian members of the study group, notably Prof. Ahmed El Fani, of the Free University of Tunis, Mr. Lamine Chabbi, a former Minister of Education, and Mr. Mahjoub Ben Milad, head of the teachers' training college. The chairman of the study group was Dr. J. W. Cook, vice-chancellor of the University of Exeter, and much of the discussion centred on papers which had been prepared in advance by some of the participants.

The Tunisian Minister of Education, Mr. Mahmoud Messadi, presided at the public inaugural session, and in a stimulating and scholarly address referred to Tunisia's cultural background, and outlined the rapid educational progress which has been made since independence, and the plans for future development. Already about a fifth of the national income is being spent on education; nearly half the children now receive primary education, which is expected to become universal within the next ten years. There are several institutions of higher education, including a training college for secondary school teachers, a traditional Muslim university, and the Institut des Hautes Études, affiliated to the University of Paris. Some of these will constitute the nucleus of the new university. In a subsequent session, Mr. Chabbi gave a more detailed and penetrating analysis of the prospective functions and scope of the new university, closely in line with the traditional concepts of a university of Western Europe. He emphasized the need for autonomy, and stressed the importance of vocational guidance with a view to a satisfactory distribution of students among subjects at a time when, for example, the demand for engineers and technicians could absorb the entire output of the secondary schools. He envisaged the university as a lively institution orientated to the service of the community, its research activities being planned in co-operation with consultative bodies representing government and industry.

Prof. B. A. Fletcher, vice-principal of the University College of Rhodesia and Nyasaland, went even further in his concept of the social functions of a new university in a new country, and indicated how the institute of education under his direction provided an advisory service for the government and for industry. This view was challenged by Prof. Polanyi who, while accepting the principle that individual members of a university might be available for consultation, insisted that the university as a body should not attempt to offer authoritative opinions. He remarked that the Royal Society had long since found it expedient to refrain from giving a collective opinion on scientific matters on account of its earlier unfortunate experiences. Prof. Polanyi also disagreed with the suggestion of Prof. Fletcher that the great discoveries of modern physics have been the result of team work. According to Prof. Polanyi, all the great scientific discoveries are individualistic. He was sceptical about the feasibility of control and co-ordination of research, and claimed that research in the natural sciences is self-co-ordinating. Scientific discovery depends on the reliability, the systematic character and the intrinsic interest of the work. He defined the fields of enquiry for which the university is the only place, and those, stimulated perhaps by the possibility of practical application, which may also properly be carried out in the university. Unsystematic technology and invention, he thought, should have no place in the university.

Prof. E. G. Malherbe, vice-chancellor of the University of Natal, referred to the industrial research institutes established in association with his university, the head of the institute being given professorial rank. This helped to interest students in careers in industrial research, and the institutes often encountered long-term theoretical problems suitable for academic study in the appropriate university departments.

There was much discussion about the claims of society on the university in a new country, and how they could be met in ways consistent with academic freedom and university autonomy. Much was said about the pressures liable to be exerted for control by government of the output of teachers, engineers and other professional personnel; of the pressure to increase numbers and to reduce the length of courses in the interests of more rapid output. It was agreed that such pressures should be resisted. But although there seemed such general agreement about these principles in the abstract, one had the impression that different members of the study group interpreted them variously, in the light of the circumstances of their own countries. It is not surprising that the attitude of the community to the university in a poor and rapidly developing country is inclined to be more utilitarian than in a country where both the community and the university form part of an old established order. However, in the last analysis, as Dr. Salwa Nassar, of the American University of Beirut, so aptly remarked, the role of the scholar in society is to be a scholar.

Prof. Ehsan Naraghi, of the University of Tehran, wondered if pure research was too much of a luxury in an under-developed country. This brought a spirited rejoinder from Prof. Edward Shils of Chicago, who insisted on the need to have in the university the stimulus of taking part in extending the frontiers of knowledge. There was, perhaps, insufficient attention given at the meeting to the criteria for establishing and maintaining academic standards.

In such a gathering at such a place, constantly recurring themes were, not surprisingly, the influence of religion and the problem of language. Dr. Romila Thapar thought that authoritarian religious traditions in India had promoted an attitude in the student of unquestioning acceptance. Mr. M. Bashir was even more gloomy about the stultifying influence in Pakistan of this authoritarian concept of education. As this was linked with the Islamic religion, his views were hotly contested in a meeting where the Arab countries were strongly represented. An interesting point which some had not appreciated was that the problem of the language to be used as the medium of instruction was not the same problem in the Arab countries, as it is in India, for example. In the latter case the choice is between English and a synthetic national language, Hindi, bearing little resemblance to the host of different languages in use in different parts of the country.

In the Arab countries, there is a single national language and the choice is between English or French, and Arabic. In Tunisia the matter had been virtually decided by the decision of the Government to adopt bilingualism (Arabic and French). Mr. Cecil Hourani, adviser to President Bourguiba, made a strong plea for the simplification and clarification of the Arabic language. Attempts to give a complete education in the Arabic language, as is attempted at Damascus, cannot be successful, he thought. Re-fertilization of the Arab mind can take place only by contact with non-Arab sources. This view did not pass unchallenged, and the Arabic language was defended by the Lebanese Ambassador to Morocco, H. E. Selim Haidar, who claimed that Arabic is by its nature a scientific language ; he thought that an Arab student would gain just as much from instruction in modern science in Arabic as in a Western language. Interesting views were expressed by Mr. Cecil Hourani, and by his brother, Mr. Albert Hourani of Oxford, about the present and future roles of the three types of university which are found in some countries of the Middle East ; namely, the traditional Islamic institutions, the 'foreign' universities, such as the American University at Beirut ; and the modern State universities. Only the latter were thought likely to survive as significant influences in the national life.

The idea of a 'foreign' university out of touch with indigenous culture, nationalist sentiment and tribal loyalties was evidently in the minds of the two Nigerian contributors from Ibadan—Dr. E. Njoku, who sent a paper, and Dr. H. A. Oluwasanmi, who attended the meeting. Nigeria demanded a university as good as those in other countries. If academic freedom is a necessary element, then it must exist in Nigeria. But the principle of academic freedom is too shallowly rooted to withstand the over-riding claims of the tribe. Cultural activities, being largely European, make the university seem more exotic than it is, and this causes resentment.

The Turkish participant, Mr. Osman Okyar, suggested that the wave of nationalism which accompanies independence may be a passing phase, and he instanced the support now being given by his Government to university institutions of foreign origin.

The Tunis seminar provided a forum for a useful exchange of views on problems which were approached from several different points of view, and the full publication of its proceedings, which is expected later, will be of interest to all who are concerned with higher education in the emergent countries of Africa and Asia.

J. W. Cook

RADIOACTIVE FALL-OUT

THERE have been four important and authoritative statements on hazards from man-made radiation : a report by the Medical Research Council in Britain, published in 1956[1]; a report by the U.S. Academy of Sciences, also published in 1956[2]; a report by the United Nations Scientific Committee on the effects of atomic radiation, published in August 1958[3]; and a statement on this last report by the Medical Research Council, which appeared simultaneously with it[4]. In a statement which the Prime Minister circulated in the Official Report of the House of Commons (*Hansard*, April 28) he refers to the United Nations report ; but his own statements, and in particular those publicized by the Press, are mainly based on the first of these publications, which in some respects has become obsolete.

This is particularly true of the ratio 100 : 22 : 1 (or somewhat more than 1), which plays such a prominent role in the Prime Minister's replies. It is said to be the ratio between the amounts of radiation received (*a*) from natural sources (background radiation), (*b*) from medical and industrial uses, and (*c*) from fall-out due to nuclear bomb-tests. For several reasons this ratio is no longer valid. First, the Medical Research Council has meanwhile revised its estimate of the dose of radiation which the average individual receives through X-radiation. In concordance with the estimate made in 1956 by the U.S. Academy of Sciences, the Medical Research Council in its 1958 statement admits that in countries with highly developed medical services the amount of radiation from diagnostic X-rays may well be as high as the background radiation. In other words, the ratio between the first two items may be 100 : 100 instead of 100 : 22.

For the discussion of radiation hazards from bomb tests this is relevant, because certain radiation effects are cumulative, and even if X-rays should be used more sparingly in the future, a high amount of X-radiation will have to be reckoned with as an unavoidable ingredient of civilization. It should also be pointed out that, contrary to the Prime Minister's statement, these figures (22 per cent in the older report, 100 per cent in the newer) refer only to diagnostic X-rays, and include neither therapeutic nor industrial radiations.

Secondly, when the Prime Minister states that radiation from nuclear bomb tests amounts to 1–2 per cent of the background radiation, it is not clear to what he refers. At the present time, there is a constant increase in the amount of fall-out, and figures which are valid in one year will be too low already in the next. The Medical Research Council report of 1956 estimated that, if bomb tests were to continue indefinitely at the then existing rate, an equilibrium between formation and decay of radioactive matter would be established in about a hundred years and that in this equilibrium state radiation from fall-out would be approximately 1 per cent of that produced by natural sources. However, a warning was given that this might represent an under-estimate if "present rates of firing were increased and particularly if a greater number of thermonuclear weapons were tested". From the fact that strontium fall-out during the past year has increased far beyond expectation, we may suspect that this warning is applicable, and that the 1956 estimate of fall-out rate at equilibrium was an under-estimate.

Cæsium-137, Carbon-14 and Strontium-90

There is a further reason why the Prime Minister's estimate of man-made radiation is too low. This is the discovery of two more radioactive elements in fall-out, namely, cæsium-137 and carbon-14. The former had just been discovered when the 1956 report of the Medical Research Council came out. It is briefly mentioned in this report, but its effects are not included in the estimate of fall-out. In the United Nations Report this omission has been amended, and the final figure for fall-out radiation, if tests should continue at the present rate, is several times as high as that quoted in 1956 by the Medical Research Council, which accepted this higher figure in its 1958 statement. This means that the amounts of radiation received at equilibrium from natural sources, from diagnostic X-rays (*not* including radiotherapy and the use of radiation in industry and research) and from fall-out are estimated to occur in the proportion of 100 : 100 : between 2 and 4. However, even this is still an under-estimate of the amount received from fall-out; for quite recently—too recently to be mentioned in the United Nations Report—carbon-14 has been found to be present in fall-out from nuclear explosions. According to Prof. L. Pauling, carbon-14 is by far the most dangerous component of fall-out, because it is produced in large amounts at nuclear explosions and takes thousands of years to lose its radioactivity.

It should be stressed that strontium-90 is peculiar in its effects in that it is taken up selectively into the bones, especially those of growing children. The amount so taken up is evidently related to the amount coming down in rainfall, but the relationship is far from straightforward. It depends on the type of soil and vegetation in the fall-out area and on the kind of food by which it is introduced into the human body. The United Nations Committee estimated that for the same amount of fall-out the average concentration of strontium-90 will be five to six times as high in the bones of peoples living mainly on a plant diet than in those of peoples with a milk-type diet. The Medical Research Council accepted this estimate in its statement.

Biological Hazards of Radiation

A clear distinction should be made between effects on the individual and effects on the human race. The former result in sickness and death of exposed individuals; the latter are a threat to the future of mankind.

Effects on the individual. High doses of radiation cause sickness which may result in death; but, barring accidents, nuclear bomb tests will not cause exposures to such high doses. Low doses may result in cancer, often after many years of apparent well-being. The main types of cancer which may be expected are leukæmia and bone cancer, the latter in particular through accumulation of strontium-90 in bones. For animals, there is also convincing evidence that low doses of radiation shorten life-span without obvious disease. Whether this is true also for the human species is still under debate; it certainly is necessary to keep the possibility in mind.

Genetical effects. These occur in the form of gene mutations, and result in hereditary changes. There is no recovery from mutation. Once a mutation has occurred, there is only one way by which mankind can get rid of it: death or sterility of the individuals carrying the mutated gene. Mutations may be good, neutral or harmful in their effects; but in any species which, through long periods of natural selection, has become endowed with a well-working assembly of genes, the vast majority of mutations are harmful. For reasons which cannot be discussed here, even high doses of radiation are not likely to result immediately in the birth of malformed or otherwise obviously handicapped children, except when a pregnant woman is exposed. But any increase in the number of mutations is bound eventually to increase the number of such abnormal children, even though their occurrence may be spread over centuries. In addition, there will be a similar increase in the number of less-drastic hereditary changes, and these will swell the proportion of chronically ailing, emotionally unstable, mentally dull or otherwise sub-standard types in the human race.

The Threshold Concept

There is full consensus among scientists that radiation produces harmful effects on the exposed individual as well as on the human race as a whole; but opinions differ as to the magnitude of the damage expected from nuclear bomb tests. This is not surprising in view of the difficulty of obtaining pertinent data for human beings and the uncertainty factor involved in extrapolation from animal data. Questions directed in the House to the Prime Minister have shown that some Members of Parliament are aware of the key position which the threshold concept holds in all attempts to assess radiation damage quantitatively. Mr. Aneurin Bevan stressed the point that organisms differ in their sensitivity to radiation. This is true, but it is not relevant to the question whether or not there is a lower threshold to certain types of radiation damage. Whether or not there is such a threshold, individuals, organs and cells may and do differ in their sensitivity to radiation; but where a threshold exists, doses below a certain level of exposure—which may not be exactly the same for every individual, organ or cell—are entirely ineffective. Given the right amount of information, one can therefore determine a safe level of exposure below which no damage is to be expected. Where there is no threshold, no such safe level exists, and even the lowest exposure will produce damage in proportion to its magnitude.

There is very good evidence for affirming that there is no lower threshold for the production of mutations by radiation. In view of misleading articles in the daily Press, I want to emphasize that this conclusion is not invalidated by very recent experiments on mice, which indicate that the genetical effectiveness of radiation in certain types of cell depends on the time over which a given dose of radiation is spread. Estimates of the actual amount of genetical damage involve so many assumptions that they cannot be more than very rough approximations. For the case that bomb testing continues at the present rate, Prof. Pauling estimates that in about a hundred years, when equilibrium has been reached, about 15,000 seriously defective children will be born each year as the result of the tests. This value is within the wider limits of 1,000–40,000 adopted by the United Nations Committee. It does not include abortions, miscarriages, stillbirths and many minor hereditary defects which will have been produced at the same time. Nor does it take account of carbon-14 which, because of its very slow rate of decay, continues to produce radiation damage over many thousands of years. According to Pauling, already the bomb tests carried out so far "will ultimately produce about 1 million seriously defective children and about 2 million embryonic and neonatal deaths, and will cause many millions of people to suffer from minor hereditary defects".

There is as yet no evidence available which would allow a decision as to whether or not there is a lower threshold to the production of cancer, leukæmia and, perhaps, premature ageing by radiation. Recognizing this, the United Nations Committee has made all its calculations concerning these effects in duplicate: once on the assumption that a threshold exists, and a second time on the assumption that it does not exist. In the first case, as in that of mutation, even the lowest additional amount of radiation is dangerous in proportion to its magnitude; in the second, it seems likely that the present amount of fall-out is still below the danger level.

It should, however, be evident that in a matter like this—a matter of life and death for hundreds of thousands—one should act on the basis of the more pessimistic view until convincing evidence for the more optimistic one has been furnished. This seems also the opinion of the Medical Research Council. In its 1958 statement it writes: "In our view, it is not possible at this present time to decide whether there is or is not a threshold dose concerned in the induction of leukæmia and cancer, and the only scientific attitude to the problem at present is one of suspended judgment. Nevertheless, the significance of the alternative points of view in determining the ultimate assessment of risk should be clearly understood so that those who have the responsibility for acting on such assessments should be fully aware of the alternative possibilities that need to be taken into account".

The Role of Strontium

Strontium, as has been pointed out, plays a special part as a potential cause of bone cancer. It is therefore very disturbing to learn that the amount of this element in the rainfall over the United Kingdom has doubled during the past year. It is difficult to understand why this seems to cause little anxiety to the Prime Minister and his advisers. The amount of strontium-90 in the bones is measured in strontium units (1 strontium unit (S.U.) = 1 micromicrocurie of strontium-90 per gram of calcium). 1,000 S.U. is the industrially permissible dose; but in 1956 the Medical Research Council recommended that in a population with many growing children the allowable dose should not exceed an average of 100 S.U. and "that immediate consideration would be required if the level in the general population showed signs of rising greatly above 10 S.U.". The United Nations Report of 1958 presents figures which show that at the end of 1957 the average bone content of strontium-90 was 2·3 S.U. in countries with a milk-type diet and 14 S.U. in plant-eating communities, in both cases as the average over the next 70 years. This was before the spectacular increase of strontium-90 in rainfall, and although—as pointed out above—the relation between strontium in rainfall and strontium in the bones is complex, it cannot be doubted that this increase in fall-out will be reflected in a marked increase in the strontium-90 content of bones. If there has been a similar increase of strontium-90 fall-out in other parts of the world, the strontium content of the bones in some plant-eating peoples may already be well in excess of 10 S.U.

In regard to the future, the United Nations Committee estimated in 1958 that, if bomb tests continue at the same rate as between 1954 and 1958, the content of strontium-90 in the bones of people living about a hundred years hence will be 40 S.U. for countries with a milk-type diet and 240 for countries with a plant diet. Such figures, according to the Medical Research Council report, would certainly call for immediate consideration. Since the recent rise in strontium-90 fall-out has been so unexpectedly high, this situation may arise in a much shorter time.

Background Radiation

The Prime Minister seems to think it a cause for complacency that the human race has survived in spite of a considerable amount of radiation from natural sources. The opposite is true. It is highly probable that natural radiation causes many cases of leukæmia and bone cancer. There is nothing we can do about it. We just have to put up with it, as we have to put up with earthquakes and hurricanes. But the fact that many people are killed through such natural catastrophes does not make us complacent about death-rates from industrial accidents or careless driving. The fact that there is this inescapable amount of natural radiation, and that recently there has been added to it probably more than an equal amount of medical radiation, makes it even more imperative to keep radiation from any additional sources as low as possible.

For the genetical effects of radiation the situation is somewhat more complex and cannot be discussed here in detail. Only so much can be stated: mutations are the ultimate raw material for natural selection. Without mutation, there would have been no evolution. Naturally occurring mutations, too, are usually harmful, but Nature—in contrast to man—can afford to waste thousands of ill-adapted individuals for the sake of a single better adapted one. It is probable that in the course of evolution every species establishes a balance between the frequency with which its genes mutate and the amount of natural selection to which it is exposed. It is also probable that for mankind this balance has already been upset through the relaxation of natural selection, and that the frequency of even natural mutation may be rather higher than is desirable. Any additional mutations will shift the balance even further in the direction of genetical deterioration.

Manufacture of Nuclear Devices by Private Firms

I should like to make one final point. Prior to the discussion of radioactivity in the House of Commons on April 28, the Prime Minister was asked a question regarding safety measures in private firms which produce nuclear devices. The Prime Minister answered that the Atomic Energy Authority exercized the same sort of control and supervision in these firms as in its own establishments doing similar work. No doubt this is true; but there is a different angle to this question. The industrially permissible dose has been lowered repeatedly, and at present is only 1/14 of what it was in 1934. Yet it is still fairly high, and, if received in full by many employees for many years, would be a cause for concern, especially to geneticists. It is, however, asserted that very few workers in Government plants receive anything like this dose. In 1957, Prof. H. J. Muller, the leading expert on the genetical effects of radiation, pointed out that in private firms "the pressure of costs will tend to prevent the observance of more rigorous standards than those officially recognized, and there is therefore a danger of considerable radiation being received from the so-called peaceful atom, unless we further lower the ceiling". It would seem that in the United Kingdom we are reaching the stage where such a lowering of the officially permissible dose for employees in nuclear establishments should be taken into serious consideration.

OBITUARIES

Dr. Jesse P. Greenstein

BIOCHEMISTRY and cancer research lost one of its leading figures with the sudden death on February 12 of Jesse Phillip Greenstein. He had been chief of the Laboratory of Biochemistry at the National Cancer Institute, Bethesda, Maryland, since 1946 and held this position at his death.

Born in New York in 1902, he graduated first from the Polytechnic Institute of Brooklyn in 1926 and then took an M.S. and finally Ph.D. in biochemistry at Brown University. In the next two years he held fellowships at Harvard (Prof. E. J. Cohn) and at the Kaiser-Wilhelm Institute, Dresden (Prof. M. Bergmann). This one year spent with Bergmann in Germany confirmed Greenstein's interest in amino-acids and settled much of the pattern of his future researches. Two valued reference books he always kept to hand on his desk were the collected works of Emil Fischer and of Max Bergmann. He returned to Harvard and during 1933–39 was instructor in biochemistry at Harvard College, and a research associate of Harvard Medical School. His research interests in this period were concerned with peptide synthesis, the physico-chemical characteristics of peptides in solution and the role of sulphydryl groups in protein structure and denaturation. Much of this work was of a new and fundamental nature and has retained a permanent place in the literature.

Leaving this special field of research, Greenstein entered the second and major phase of his career when in 1939 he moved to join the staff at the National Cancer Institute. He extended his earlier interests to include nucleoproteins and nucleic acids, and then with a team of workers devoted his energies to a survey of the enzyme spectra of living cells, normal and neoplastic. Greenstein's activities in this field undoubtedly stimulated the post-war surge of research into the chemistry of growth. With his colleagues he published more than a hundred papers in the period 1940–47 dealing with this problem. Much of this work was incorporated in his first book published in 1947, "Biochemistry of Cancer". This book has remained the most important and most quoted survey of experimental cancer research. It was revised and of necessity greatly extended in its second edition in 1954 and is unlikely to decrease in value for many years to come.

While retaining an interest in enzymology, Greenstein turned his interest back to amino-acid chemistry. Papers published over the period 1948–58 describe the use of enzymatic methods for the resolution of amino-acids. Making use particularly of a kidney enzyme, designated 'acylase', Greenstein and his colleagues showed that by asymmetric hydrolysis of acyl-DL-amino acids both the pure L- and D-forms could be obtained in good yield and of high optical purity. During the past three years the application of these pure isomers in nutritional and metabolic experiments was being studied.

The volume of published work conveys some idea of Greenstein's immense energy. The carpeted office approached through a protective screen of secretaries was not for him. Instead, there was an open door and a pair of hands ready, indeed anxious, to help with practical work and a fund of advice and experience. He was always anxious to help along the younger workers of his group and would always give them full credit for any achievements. He also afforded a very generous welcome to workers from many countries, and the hospitality of his family, as well as of the laboratories, must have left them with a very happy impression of American life.

Greenstein himself went outside the United States on two occasions only—to a conference at the Papal Academy in Vatican City in 1949, and to Japan in 1956. He did, however, take a very prominent part in American scientific affairs. He was, for example, a past chairman of the Division of Biological Chemistry of the American Chemical Society and a member of the National Research Council's Committee on Biochemistry. He was on the editorial boards of *Cancer Research* and *Archives of Biochemistry and Biophysics*, while in recent years he was joint-editor with Prof. A. Haddow of "Advances in Cancer Research". At the time of his death he was just completing a major treatise on amino-acid chemistry. Among many formal acknowledgments of his work were included a Distinguished Service Award from the U.S. Government (1954) and the Hillebrand Prize of the American Chemical Society (1957).

Though modest about his own contribution, he was visibly proud of the work of his section, of his country and above all of his family. He will be greatly missed and all will sympathize with those near to him at their loss.

Douglas Hamer

Dr. Greenstein's contributions extended widely in the fields of amino-acid, peptide and protein chemistry, and of nutrition. In the past few years he had devoted much effort to the elaboration of a completely soluble diet composed of chemically defined constituents; and at the time of his death he was engaged (with M. Winitz), in the final stages of a major work on the chemistry of the amino-acids, which is to appear in three volumes, of which the first is now in the press. But apart from these, his contributions to cancer research alone would have more than sufficed to establish him among the leading biochemists of his time. He was an accomplished writer, and his "Biochemistry of Cancer" had, and has, immense influence, and proved a very significant stimulus to the subject as a whole.

Of his own work, two aspects were of particular importance; first, his studies of the mechanism of production—and the significance—of the dramatic decline in liver catalase activity which is observed in tumour-bearing animals; and secondly, his analysis and comparison of the distribution and activity of a host of enzyme systems in normal and cancer cells. In spite of the extreme difficulty and complexity of these problems, there gradually emerged a real and satisfying conclusion, namely, that although tumours mostly possess the same enzymes as do normal tissues, qualitatively, none the less they tend, enzymatically, to converge to a common type, and hence show more resemblance to one another biochemically than to the normal tissues from which they arose.

All these, and many other contributions, embodied in upwards of 250 papers, brought him international acclaim. But we shall also remember him for his human qualities, and his combination of serious devotion with much courage and humour. Certainly I have good cause to be grateful for many years of happy association with him; and Bethesda without him can never be quite the same. All who admired him will be glad to know that there has now been established, in his remembrance, a Jesse P. Greenstein Memorial Foundation, to be administered by a small committee of his colleagues, and which will, in cases where it is necessary or helpful, provide tuition and support during the years of undergraduate study in the arts or sciences, "to the son or daughter of a scientist who has made notable contributions to the medical, physical or biological sciences, and who is deceased".

Alex. Haddow

Dr. Arthur Walton

Dr. Arthur Walton, who died suddenly in Cambridge on April 6, was best known for his pioneering research in the field of sperm physiology and artificial insemination of farm animals. He was born in London, on March 16, 1897, of Scottish parents, and educated in Edinburgh, first at Daniel Stewart's College and later at the University, where he obtained in 1923 the degree of bachelor of science (agriculture). It was also in Edinburgh, at the Animal Breeding Research Department, where he received his early training in research methods and published, in 1924, his first paper, on "The Flocculation of Sperm Suspensions in Relation to Surface Charge". Keen interest in sperm physiology prompted Walton to move to Cambridge and take up research on animal reproduction. In 1926 appeared his first communication in *Nature*, on "Preservation of Mammalian Spermatozoa", a subject which he expanded in the following year in his Ph.D. dissertation, and to which he devoted his special attention throughout his scientific life.

Among Walton's most outstanding contributions to the subject of sperm physiology was the first demonstration that ram semen, properly collected and stored, can be sent on long journeys to distant countries, to be used there for successful insemination of ewes; next, there were the experiments which proved that 'cold shock' can destroy the fertilizing ability of bull and ram spermatozoa. Of great scientific significance was his observation that the metabolic activity of ram and bull spermatozoa, particularly their respiration, is directly correlated with motility; and the discovery that respiring spermatozoa produce under certain conditions hydrogen peroxide which, in turn, is responsible for a gradually developing inhibitory effect on respiration and a decline in sperm motility. During his more recent investigations, Walton developed a novel and ingenious method of maintaining sperm alive for long periods, in a perfusion apparatus where nutrient substrates are fed continuously to a sample of semen and the toxic metabolites removed at the same time.

In addition to the work on spermatozoa, Walton has been keenly interested in various other aspects of reproductive physiology, including mating behaviour in animals and female fertility. He was the first to make detailed observations on ovulation in the rabbit, and to study the effect of maternal influences on the size of offspring in reciprocal crosses between large and small breeds of horses.

As a member of the University School of Agriculture and the scientific staff of the Agricultural Research Council, Walton spent nearly thirty years of his life in Cambridge, much of it in his laboratory at the Animal Research Station, in close association with many young research workers, always ready to help, to guide, and to advise. Although primarily concerned with physiological problems, Walton had also a profound knowledge in the field of general biology and agriculture. His contributions to agriculture, especially those which led to the establishment of the practice of artificial insemination in farm animals, were recognized in 1957, by the award of the Medal "for outstanding research in agriculture" from the Royal Agricultural Society of England. Walton's many friends all over the world will mourn the untimely death of this outstanding scientific worker.

J. HAMMOND
T. MANN

Dr. F. Tattersfield, O.B.E.

DR. FREDERICK TATTERSFIELD died at his home in Harpenden on May 1 at the age of seventy-eight. He may well be described as the founder of modern research on insecticides.

Dr. Tattersfield was born near Dewsbury in Yorkshire and went to Dewsbury Grammar School and the University of Leeds. From Leeds he graduated in chemistry with first-class honours. His first job was in association with the Leeds City Analyst, where for a number of years his work ranged over all the typical activities in such a department. In 1908 he joined a paint manufacturing firm; here his work was chiefly concerned with research on anti-fouling paints for ships.

Dr. Tattersfield went to France in the First World War as a founder member of the Friends' Ambulance Unit. He was invalided out in 1917, and went to Rothamsted Experimental Station, where he remained for the rest of his working life. He originally had a temporary appointment in the Chemistry Department, but he soon founded the present Department of Insecticides and Fungicides, of which he was the head for twenty-nine years.

Dr. Tattersfield's earliest work was concerned with the control of soil pests and he carried out some work on the structure – toxicity relationships of chemicals to wireworms. He also studied the factors influencing the decomposition of naphthalene in the soil and the effect of different rates of decomposition on its insecticidal action. He then proceeded to study the effect of a range of chemicals on the insects that attack the aerial parts of the plant, again attempting, so far as possible, to relate toxicity with structure in some systematic way. In the course of this work he discovered the outstanding ovicidal properties of dinitro-*o*-cresol, a substance which has been used as a winter wash for fruit trees ever since. At that time chemical manufacturers had little confidence in the development of effective synthetic organic chemicals for pest control, and Dr. Tattersfield in his search for highly biologically active chemicals turned his attention to plants. He examined a wide variety of plants for insecticidal activity, but his main work was done on the fish poison group, particularly *Derris* spp. and *Tephrosia* spp. and on *Pyrethrum*. His contributions on the isolation of the active principles of these plant products, the assessment of their insecticidal activity and their chemical estimation were quite outstanding. He studied many phases of the production and assay of pyrethrum as an insecticide and played a large part in the founding of the Kenya pyrethrum industry, an industry which has proved of the greatest value to the economy of the country.

During the course of his work, Dr. Tattersfield evolved precise methods of administering doses of chemicals to insects and introduced statistical procedures for the quantitative assessment of results.

The mere cataloguing of Dr. Tattersfield's contributions to knowledge on insecticides, substantial though they are, gives a very inadequate idea of what the subject owes to his influence which, fortunately, was widely felt owing to his high international reputation. When he entered the subject the standard of work was very low and no serious attempt was being made to obtain reproducible quantitative results of known significance. Dr. Tattersfield insisted on the importance of precise quantitative data where the factors known to influence the results were standardized, so far as possible, and where both the design of the experiment and the results would satisfy accepted statistical criteria. In doing this he set standards which, over the course of years, have been accepted to the inestimable benefit of the subject.

Dr. Tattersfield was always a source of inspiration to his colleagues, to whom he was unfailingly kind and helpful. His justly acquired high reputation never changed his modest and unassuming personality, and his death will leave many of us with a deep sense of personal loss. He leaves a widow and one son.

C. POTTER

Dr. G. K. Groetzinger

DR. GERHART K. GROETZINGER, a principal scientist at the RIAS Division of the Martin Company, Baltimore, died on March 30 at the age of fifty-one. Born in Vienna, Austria, he received his doctorate in physics from the University of Vienna in 1931 and was a member of the faculty there before going to the United States in 1938.

Dr. Groetzinger has been associated as a faculty member, research worker and consultant with the University of Illinois, Ohio State University, the Enrico Fermi Institute for Nuclear Studies at the University of Chicago, the Lewis Laboratory of the National Advisory Committee on Aeronautics, and the Los Alamos Laboratory of the Atomic Energy Commission. Dr. Groetzinger joined RIAS in January 1956, and his work there since then had dealt primarily with solid state physics and cosmic-ray experiments performed in Earth satellites and high-altitude balloons. His work included some of the pioneer investigations of such fields as magneto-photoelectric effects in semi-conductors and the nuclear interactions of mu mesons.

Mr. H. Curtis

MR. H. CURTIS, production director of Leda Chemicals, Ltd., died on May 20 at the early age of thirty-nine.

Mr. Curtis graduated with honours at the Manchester College of Technology in 1941 in chemical engineering. After working during the War with chemical firms, he went to Sondes Place Research Institute in 1948 and in 1950 to Leda Chemicals, Ltd. He was appointed as a chemical engineer at a time when the firm was starting to manufacture fine chemicals. During his service with the firm, Mr. Curtis designed and constructed plant for the manufacture of quaternary ammonium compounds, cyanamide monomer and a range of other fine chemicals, notably rubber chemicals such as alkyl dithiocarbamates.

During the year 1953–54 Mr. Curtis went to Israel and worked on process development with Israel Mining Industries, Ltd. On returning he was elected a director of Leda Chemicals and its associated companies, Cunningham Smith, Ltd., and Lea Valley Chemicals, Ltd., becoming responsible for production and chemical engineering in these companies.

NEWS and VIEWS

Mechanical Engineering at Belfast : Prof. F. V. Warnock, O.B.E.

Prof. Frederick Victor Warnock will retire on September 30 from the chair of mechanical engineering at The Queen's University of Belfast. He received his engineering education at the Royal College of Science, Dublin, and has been a member of the Faculty of Applied Science and Technology at Belfast since its inception in 1921. He is now the sole surviving founder member. He was the first occupant of the chair of mechanical engineering, founded in 1955, though he had served as head of the Department in the Belfast College of Technology and as extra-mural professor in the University since 1938. Many of his former students hold positions of responsibility in universities, industry and research organizations, and they would all testify to his skill as a teacher. A wider public is familiar with his clarity of exposition through his book on "Strength of Materials".

In his long academic career at The Queen's University, Prof. Warnock has been actively concerned in the most successful collaboration between the University and the College of Technology, and as professor and dean of the Faculty, has been responsible for the planning of the new engineering building which will serve the needs of both bodies for advanced engineering studies. His main research interest lay in the shock properties of metals and, though he published a number of papers in the *Proceedings* of the Institution of Mechanical Engineers and of the Iron and Steel Institute, these do not reveal the full importance of his work. During the Second World War he was responsible for some experiments in shock testing of steels on behalf of the Admiralty, and these results have never been published. Much important work has been done on repeated impact testing in other universities by men who learned their techniques and received their inspiration from Prof. Warnock.

The Editors regret the delay in publishing this issue of "Nature". From now on, every effort will be made to bring out succeeding issues as quickly as possible until the normal date of publication is resumed

Dr. B. Crossland

The appointment of Dr. B. Crossland to the chair of mechanical engineering at The Queen's University, Belfast, in succession to Prof. Warnock, has recently been announced. Dr. Crossland was educated at Simon Langton's Grammar School, Canterbury, and Nottingham University College, where he took a London honours degree in 1943. He obtained his practical experience with Rolls-Royce, Ltd., Derby, first as an apprentice and then as technical assistant in the experimental vibrations section which dealt with both reciprocating and the then novel gas turbine engines. After a brief period as a lecturer at Luton Technical College he was appointed to the staff of the Mechanical Engineering Department, University of Bristol, where in 1957 he was promoted to senior lecturer.

In 1947 Dr. Crossland obtained the degree of M.Sc. for a thesis on the "Axial Vibration of Crankshafts" and in 1954 the Ph.D. degree for a thesis on "The Effect of Fluid Pressure on the Shear Properties of Materials". These theses reflect a gradually changing preoccupation from problems in the field of vibrations and machines to those concerned with strength of materials, in particular plasticity and fatigue. To these latter subjects he has, in recent years, made important contributions; for example, in elucidating the effect of hydrostatic pressure on brittle materials, in determining the behaviour of thick tubes subjected to internal pressure, and in investigating the behaviour in relation to fatigue of materials subjected to cyclically varying triaxial stresses.

Automatic Programming of Digital Computers

The first national conference devoted to problems of automatic programming of digital computers was held during April 1–3 at Brighton Technical College. Organized by the Mathematics Department, the conference was attended by 111 representatives of computer manufacturers, research establishments, industry, universities and technical colleges. The conference recommended that Brighton Technical College be asked to establish, with the help of the profits of the conference and the assistance of computer manufacturers, a national information centre on auto-programming. The aim of this centre would be to collect a comprehensive library of documents on the subject, to make available to subscribers, by a postal service and otherwise, copies of any such document required, and to publish, from time to time, in the British Computer Society's *Bulletin*, lists of new documents acquired. It was also suggested that the British Computer Society be asked to co-opt on to its sub-committee concerned with problems of a universal autocode a representative of the Brighton Technical College, as organizers of the conference. A list of definitions of commonly used terms, such as 'interpretive routine', 'translation routine', 'compiler', 'generator', etc., suggested in a paper by Dr. Stanley Gill, was circulated to the participants for comment. This list is also to be published in the Computer Society's *Bulletin* so that any member of the Society who was not at the conference may take part. The proceedings of the conference are to be published by the Pergamon Press.

British Association of Corrosion Engineers

The British Association of Corrosion Engineers was formed at a luncheon given under the auspices of *The Corrosion Engineer* on May 29. The objects of the Association will be generally to promote the dissemination of technical information about corrosion matters and to develop by means of social activities the free interchange of information among members. In due course the Association, which is, of course, essentially non-profit making, will progress towards the establishment and acceptance of suitable qualifications for corrosion engineers, and the promotion of standardization in the terminology and techniques of corrosion control. When the Association is in full operation it is intended to hold full-scale meetings with papers, films and discussions, which should be of great benefit to the corrosion engineering profession as a whole and which will promote and foster its growth and development as well as being of general service to industry. Further information can be obtained from the Hon. Secretary, British Association of Corrosion Engineers, 97 Old Brompton Road, London, S.W.7.

The Average Length of Working Life

FIGURES showing the average expectation of working life for males in Great Britain, which have been prepared by the Ministry of Labour and National Service, are set out in a booklet called "The Length of Working Life of Males in Great Britain" (pp. 24. London: H.M. Stationery Office, 1959. 3*s*. 6*d*. net). The publication contains tables and charts which are designed to provide answers to questions like: How many years on the average can men of a given age expect to continue at work? What proportion of the men of a given age in the working population can expect to be still working at sixty-five and then have a period of retirement? What were the estimated losses from the working population in 1955 owing to death and retirements? For example, the 1955 table shows that on the average boys aged fifteen can expect to have 48·4 years in the working population. Of the men aged thirty in the working population, 62 per cent can expect to be still in the working population at age sixty-five. For those men aged sixty-five in the working population, 75 per cent can expect to retire at some later age. A very large population (31 per cent) can expect to retire before reaching their sixty-sixth birthday. A comparison between 1931 and 1955 shows that over this period the expectation of working life at birth rose from 40·6 years—an increase of 12½ per cent. This was entirely due to the reduction in mortality-rates, which outweighed the effect of the raising of the school-leaving age and of the movement to earlier retirement. There is a growing demand for the kind of information given in these tables because private pension schemes and the new social security legislation introduced into Britain during the present century have made it possible for an increasing number of people to spend a significant number of years in retirement. 'Probability of survival' tables have been in use for a long time, but since there is now a substantial difference at particular years of age between the average expectation of life and the average expectation of remaining in the working population, separate tables show the expectation of working life.

Training for Skill

"Training for Skill", by Lady Gertrude Williams, issued as No. 205 in the Fabian Research Series (pp. 28. London: Fabian Society, 1959. 2*s*.), is based on the factual information regarding boy apprentices collected in a survey, "Recruitment to Skilled Trades" (see *Nature*, 181, 373; 1958). It also covers the Carr report, "Training for Skill", which is criticized for failing to face the profound changes in industrial structure and in public education which have made many of the traditional methods inappropriate to present needs, although the report contains an agreed criticism of the inflexibility of the present regulations. The pamphlet urges that some new method must be found which ensures that an adequate supply of training vacancies is available to provide enough skilled workers for future needs, and that the costs of training are spread more justly over all the firms that benefit from the employment of adult skilled men. It should also ensure that men capable of learning to do a job are not permanently excluded simply because they missed the opportunity to train when they were sixteen years old, that the quality of teaching in the workshops is improved, and that the theoretical instruction is graded to suit the capacities of the pupil. Lady Williams refers to some schemes for group training recently instituted and an extension of the 'sandwich system' as possibilities to be explored, and also suggests that apprenticeship might come to be regarded more definitely as a function of education rather than of industry. In an introduction in which she discusses industry's present needs and the limits of mass production, Lady Williams stresses the real danger that there will not be sufficient skilled workers available to understand and execute the instructions of the increased number of scientific advisers and technologists in industry.

Technics and Purpose

Two additional booklets have been announced in the admirable series launched to examine the issues arising out of the growing importance of scientific techniques in society, the rapid expansion of technological and other education and the purposes and values involved in the light of the Christian faith. The first (On Being a Technologist. Technics and Purpose, No. 5. Pp. 33. S.C.M. Press, Ltd., London, 1959. 2*s*. 6*d*. net), by Prof. D. G. Christopherson (Imperial College of Science and Technology, London), suggests that, contrary to all the pessimistic views of the persuasive advocates of 'Admass', the total responsibility shared by the members of an industrial society has increased. Once this belief is accepted it calls for a large extension of the attitude of mind formerly associated with the professions; many more people will have to make judgments based on knowledge and reason. Such a society will become increasingly individual and less amenable to the techniques of mass suggestions.

The second (The Educated Man Today and Tomorrow. Technics and Purpose, No. 6. Pp. 26. S.C.M. Press, Ltd., London, 1959. 2*s*. 6*d*. net), by Sir John Wolfenden, is noteworthy not only because it paints a clear picture of an educated man but also because it does so without becoming trite, or condescending. Besides those qualities of character which are the hallmarks of education, Sir John believes that the educated man will accept his place in the world of Nature and will see that he understands what the scientists and technologists are doing, the nature of their thinking, and, as their numbers and influence are continually increasing, the way in which they should be educated. The third requisite for an educated man put forward by Sir John shows a remarkable likeness to that advocated by Prof. Christopherson, albeit arrived at from a different approach. Prof. Christopherson writes, "Somehow or other, if a man is to do a proper job he must find means of continuing the process of education through his whole professional life, and the need to do so is in itself a stimulant to thought not only about the immediate problems of the profession but about the deeper problems of purpose, proportion and responsibility". For Wolfenden, "the restlessness of the human mind is a divine restlessness; and however solid these brick walls may seem to be, it is part of man's nature that he cannot resist banging his head against them. For it is not in the problems of our relations with other human beings or of our relations with the world of Nature that the ultimate problem lies; it lies in our relations with what is neither of these. What is very clear is that an education with this basis will not end at school-leaving age, or with the acquisition of a university degree. There is no reason to suppose that it ends with the grave".

Electrotechnology in Australia

The annual report for 1957–58 of the Division of Electrotechnology of the Commonwealth Scientific and Industrial Research Organization of Australia describes the three main activities of the Division: the maintenance of the Commonwealth standards of measurement of electrical quantities, including the standard of frequency; calibration of electrical and magnetic instruments; and research on the improvement and extension of the electrical measuring and standards facilities and on the dielectric properties of insulating materials and the microwave spectra of gases. New apparatus installed includes a small vacuum evaporation plant; a calculable capacitor and associated measuring equipment; and facilities for making impedance and other measurements at microwave frequencies chiefly within the 9,000 Mc./s. range. The hyperfine structure of the microwave spectra of heavy-water molecules is being analysed on the high-speed digital computer *Silliac* to determine more accurately the electric field gradient at the position of the deuteron nuclei in these molecules and to estimate the magnetic constants governing the smaller effects observed in the spectra. Special furnaces have been constructed to assist in the determination of the conditions required for the successful growth of large single crystals of organic materials, and the study of the dielectric properties of polycrystalline materials and liquids has been extended. Both experimental and theoretical work has been carried out on dielectric breakdown in the alkali halides and a theoretical study based on the harmonic motion of the interacting electron–lattice system has been made of the superconducting specific heat and transition temperature of multivalent metals.

Wool Industries Research Association

The report of Dr. A. B. P. Cassie, director of research of the Wool Industries Research Association, presented to the annual general meeting of the Association on April 7, includes, besides details of the membership of the Council and Committees and a list of staff, a bibliography of publications in 1958, including lectures given by members of the staff, patents and some forthcoming publications (Wool Industries Research Association, Report of the Director of Research for 1958. Pp. 35. (Publication No. 212.) Headingley, Leeds: 1959). Modifications have been made to the pilot scouring plant, while methods for determining oil and grease in scoured wool and tops have been extensively investigated. Further work on the pulling of rags has confirmed that there is little, if any, difference in the quality of the yarns or fabrics prepared from the differently treated yarns. The work on examining the state of a yarn at the instant of break during spinning is now almost complete, and a technique has been evolved for determining whether the fibres slip or break when the yarn breaks for use with 'Fibro' but not for wool. Further experience with wool/'Terylene' blends indicates that there can be no guarantee against the tight ends or 'fiddle-string' fault developing, as procedures which are entirely satisfactory with all-wool yarns can give rise to snatch and stretching of wool/'Terylene' yarns without breakdown, but a procedure which seems to provide reasonable protection during cone-winding is indicated. The review of milling was expanded and work continued on the scouring of wool/'Terylene' worsted cloths. The study of damage to wool in dyeing was extended to coarse wool, and work was restarted on the efficacy of dieldrin in moth-proofing. The first part of the work on the examination of the washing process of wool by microscopical methods was completed, and determinations of the latent heat of sublimation of nitrogen-substituted amides, which contain a peptide group similar to that in keratin, suggest that the strength of this bond is 4–5 kcal. Homogenous membranes are now being used to study the effects of organic solvents on the rate of diffusion of dyes into keratin.

East Africa High Commission: Report for 1958

Approximately half the illustrated and very readable annual report for 1958, of the East Africa High Commission (pp. iv+92. Nairobi: Government Printer, 1949. 5*s*.) is concerned with research and scientific services, including some material to be found in "Colonial Research, 1957–58" and in the annual report of the East African Industrial Research Board as well as in "The Colonial Territories, 1957–58". Although more limited territorially, it has a somewhat more popular appeal and is well designed to show the important contribution which scientific research is making to development and welfare in East Africa. This is particularly true of the work of the East African Agriculture and Forestry Research Organization, the Veterinary Research Organization, the Fishery Research Organization, the Marine Fisheries Research Organization, the Trypanosomiasis Research Organization, the Virus Research Institute and the Institute for Medical Research. Expenditure on research was £806,721 and on the Desert Locust Survey £438,982, but it is stated that for the past two years difficulty in recruiting suitable technical and scientific staff has been the main hindrance to the expansion programme.

Acta Biologica Cracoviensia

A new botanical journal, *Acta Biologica Cracoviensia* (Sér: Botanique) (1, No. 1; 1958), has been published for the Polish Academy of Sciences under the editorship of Mme. Prof. M. Skalinska (Cracovie. Inst. d'Anatomie et de Cytologie des Plantes; Rue Jana 20). The contents of this first issue are partly palæobotanical, partly cytological. An article on the interglacial flora in Ganovce travertines in Eastern Slovakia is contributed by V. Kneblova; and there are short descriptive accounts of the genus *Cunninghamia* in the European Miocene by W. Szafer and of *Salvinia* and *Azolla* from the same geological horizon in Poland by M. Lancucka-Srodoniowa. The several cytological investigations, by Prof. Skalinska and her colleagues or pupils, deal with the curious behaviour of nuclei in the anther tapetal layer in species of *Cucurbita*, *Aconitum* and *Valeriana*. Up to a certain point the tapetum consists of normal uninucleate cells, but about the time of the prophase of meiotic divisions in the pollen-mother-cells some unusual cytological developments are induced: while some of the tapetal cells and their nuclei remain as before, others may become polynucleate, and yet others may show more or less conspicuous enlargement and, by endomitosis, may give rise to nuclei of different size categories corresponding to 4*n*, 8*n*, and even 16*n* chromosomes complements. These developments, described by these authors as "the differentiation of the tapetal cells", are considered to result from successive stimuli which can be related to developmental changes in the developing pollen-mother-cells and the tetrads to which they give rise. On the evidence to date, based on species drawn from widely separated families, it appears that these seemingly anomalous developments in the tapetum may well prove to be of very general occurrence. The texts are in English throughout, with bilingual titles. The journal is well produced, with a good clear type, and is illustrated by line drawings and by photographic plates of good quality.

Link between the Annelids and the Arthropods ?

A NEWLY FOUND fossil from near the base of the Cambrian of South Australia shows affinities which may throw some light on the origin of the arthropods. The new form is described by M. F. Glaessner in the *Transactions of the Royal Society of South Australia* (81, 185; 1958) and has been named *Spriggina floundersi*. It represents a new family of the polychaete annelids. The body is flat, the head being without external segmentation and having lateral extensions giving it a roughly horseshoe shape, the trunk consisting of a very gently tapering series of segments with appendages terminating in bristles, numbering up to about 40 and not differentiated into a tail. The largest specimen measured 46 mm. long and 11 mm. wide. Since fossil jellyfish are found at the same locality it is not necessary to assume that *Spriggina* was hard-bodied. Certain features of the head resemble those of the living group Tomopteridae, members of which are pelagic. It is accordingly suggested that the aberrant pelagic adaptations of the Tomopteridae may conceal more primitive characters. In particular the lateral extensions of the head of *Tomopteris* and its composite nature may foreshadow the formation of primitive arthropod head shields such as those of the Middle Cambrian proarthropod (trilobitomorph) *Marrella*, and of trilobite larvæ or primitive trilobites. This possibility does not seem to have been considered by the zoologists.

The Fairy Fly

Prestwichia aquatica, the fairy fly, is a hymenopterous insect which parasitizes the eggs of aquatic insects, especially water-beetles, including *Dytiscus marginalis* L. It was first discovered by Sir John Lubbock in 1864 in a pond in Kent and was not seen again for thirty years, when Frederic Enock found a few specimens in a horse-pond. In 1896, and again in 1898, Enock records that he was able to find aquatic insect eggs containing both male and female specimens of *Prestwichia aquatica*, which eventually he reared. The eggs were taken from the previous year's stems of the water-plaintain, *Alisma plantago-aquatica* L. In a communication to the *Journal of the Quekett Microscopical Club* (28, No. 4; 1958), C. I. Ison writes that, since the work of Enock, *Prestwichia* has probably been found only on two occasions in Great Britain. The most recent was at Loughton, Essex, on July 17, 1958, when Ison saw two female fairy flies emerge from an unidentified egg. The males are much slower in emerging. Subsequent observations showed that twenty-six days elapsed before any movement of the parasites was noticed in the host egg after oviposition, and it was twenty-eight days before any females emerged. From one 2-mm. egg of the beetle, *Ilybius ater*, five male and twelve female fairy flies emerged. Observation of *Prestwichia aquatica* at the surface film of the water showed that they are quite at home whether they are above the film in the air or below, in the water, walking upside down.

Predatory Animals in Spain

DURING the past four years organized campaigns against predators have been taking place in Spain (*Oryx*, 5, No. 1; April 1959). Among the 100,000 mammals and birds killed were 36 martens, 1,051 wild cats, 55 lynxes, 380 badgers, 7,250 eagles and other birds of prey. Such indiscriminate slaughter can only lead to extermination of the rarer species, especially, for example, of the southern race of the Spanish lynx, which is chiefly a lowland animal. Both the imperial eagle and the short-toed eagle, which lays only one egg, nest in easily accessible places and are especially vulnerable. In Spain there is as yet little interest in the preservation of wild life, and the conservation laws are not enforced effectively. Every predator is believed to be an enemy. A new conservation law will remove both the lynx and the lammergeier from the list of vermin, and will give the lammergeier complete protection for five years.

Banana Wilt Investigations

IN extended investigations of the vascular wilt disease of bananas caused by *Fusarium oxysporum* f. *cubense*, R. H. Stover has examined the evidence for clonal differentiation among wild type isolates of the pathogen (*Canad. J. Bot.*, 37, No. 2; 1959). *F. oxysporum* f. *cubense* exists in diseased rhizomes and pseudostems of Gros Michel bananas in two major clonal groups, or cultivars, designated 'Odoratum' and 'Inodoratum', because of the presence or absence of a distinctive odour from cultures after 4–8 days on various media. Three clones of the 'Inodoratum' cultivar, which are difficult to distinguish morphologically on peptone dextrose agar, were, however, distinguishable by cultural interaction and pathogenicity tests in the field. Also, some clones of the 'Inodoratum' and 'Odoratum' cultivars have been shown to differ quantitatively in pathogenicity in the field. Clone *C* from Honduras, of limited distribution, induced the most rapid disease-spread and destruction of banana mats, followed by clone *E* from Panama. There was an association between the 'Inodoratum' and 'Odoratum' cultivars and the syndromes induced in Honduras: the former usually induced strong yellowing of erect leaves, whereas the latter usually induced leaf collapse at the petiole with little or no leaf yellowing.

Exhibition of Old-time Beekeeping

AN interesting exhibition of equipment used by old-time beekeepers in connexion with their ancient craft is open until the end of September at the

Museum of English Rural Life, Whiteknights Park, Reading. This, probably unique, collection of log hives, skeps of various materials and patterns, hackles, old style wooden hives of various kinds, honey and wax extractors, drone traps, feeders, smokers, queen excluders, etc., has been collected during the past few years by the Bee Research Association and is on permanent loan to the Museum. Entrance is free and a useful descriptive catalogue can be obtained from the Museum.

International Conference on Fishery Statistics

An international meeting of experts on fishery statistics in the North Atlantic area is to be held in Edinburgh during September 22–30. The conference is being convened by the Food and Agriculture Organization of the United Nations in co-operation with the International Commission for the North West Atlantic Fisheries and the International Council for the Exploration of the Sea. Governments concerned with the North Atlantic fisheries have been invited to nominate experts directly concerned with collecting, analysing and publishing statistics on the fishing industries and trades of their countries, and the Scottish Home Department will act as hosts to the delegates. It is hoped that delegates will be able to identify the main difficulties encountered in providing statistical data for the use of Governments, international agencies and the fishing industry, and will indicate the action to be taken to eliminate or reduce such difficulties.

The Marine Biological Association of India

The Marine Biological Association of India was founded at Mandapam Camp, to promote interest in marine biological and cognate sciences. The Association was formally inaugurated by the Hon. Mrs. Lourdhammal Simon, Minister for Fisheries and Local Administration, Madras State, on January 3. The following officers were elected: Dr. S. Jones (president), Prof. R. V. Seshaiya (vice-president), Dr. R. Raghu Prasad and Dr. C. P. Gnanamuthu (secretaries), Dr. R. P. Varma (assistant secretary), Shri K. V. Rao (treasurer), Dr. P. N. Ganapati (editor), Dr. R. Subrahmanyan (joint editor), and Dr. S. V. Job (managing editor). The official organ of the Association, the *Journal of the Marine Biological Association of India*, is expected to be issued half-yearly. Membership is open to all who are interested. All correspondence should be addressed to the Secretary, Marine Biological Association of India, Marine Fisheries P.O., Mandapam Camp, South India.

University News: North Staffordshire

The following appointments, among others, have been made: Mr. E. M. Hugh-Jones, fellow and tutor of Keble College, Oxford, professor of economics, in succession to Prof. B. R. Williams; Miss A. Eden, senior lecturer in education, Homerton College, Cambridge, lecturer in education and women's warden; Dr. V. C. Ewing, pressed steel research fellow, University of Oxford, lecturer in chemistry; M. F. Newman assistant lecturer in mathematics.

Announcements

An international conference on High Energy Accelerators and Instrumentation will be held at CERN during September 14–19. Further information can be obtained from the Conference Secretariat, CERN, Geneva 23, Switzerland.

The thirteenth congress of the International Scientific Film Association is to be held in London and Oxford during September 23–October 2, under the auspices of the British Scientific Film Association. Further particulars can be obtained from the Association's office at 3 Belgrave Square, London, S.W.1.

The International Council for Building Research, Studies and Documentation is organizing an international congress, to be held in Rotterdam during September 21–25. The topics for discussion include the design and calculation of structures; research problems relating to the application of heavy concrete elements; and fundamental aspects of the transmission of knowledge. Further information can be obtained from the C.I.B. Secretariat, c/o Bouwcentrum, P.O. Box 299, Rotterdam.

The Dublin and District Section of the Society of Chemical Industry, in conjunction with the Agriculture Group of the Society, is to hold a symposium in Dublin during September 15–18. The subject will be "Chemical Aspects of the Production and Use of Grass", and it is intended that the meeting shall include the presentation and discussion of pre-printed papers, and lectures and visits to places of scientific interest. Further information can be obtained from the honorary secretary, R. O. V. Lloyd, Chemist's Laboratory, A. Guinness Son and Co. (Dublin), Ltd., St. James's Gate, Dublin.

The Electrical Engineering Department of the University of Birmingham is arranging two informal residential conferences in September 1959. The first, on dielectric devices, will be held during September 14–17, and the second, on modern network theory, during September 21–24. Preliminary programmes of papers and discussions have already been arranged. Further information can be obtained from the Secretary of the Electrical Engineering Department, The University, Birmingham 15. In order to preserve the informal nature of the conferences, numbers will have to be strictly limited.

The fourth annual conference of the British Society for the Philosophy of Science will be held at Newnham College, Cambridge, during September 25–27, when the following papers will be read: "Scientific Research and the Philosophy of Science", by Prof. H. Dingle and Prof. H. C. Longuet-Higgins; "Classification, Concept-formation, and Language" by Miss M. Masterman and Dr. A. Koslow; "Knowing and Being", by Prof. M. Polanyi and Prof. R. B. Braithwaite; "Biology and Physics", by Prof. J. H. Woodger and Dr. E. H. Hutten. Further information can be obtained from the honorary secretary of the Society, Miss M. B. Hesse, University College, London, W.C.1.

The first Congrès International de Prophylaxie Criminelle will be held in Paris during September 27–30. Further information can be obtained from M. Stanciu, 7 Avenue Général Leclercq, Boulogne sur Seine.

Erratum. In the communication entitled "Possible Causes of Geomagnetic Fluctuations having a 6-Sec. Period", by H. J. Duffus, J. A. Shand and Sir Charles Wright, published in *Nature* of May 23, p. 1479, the caption for Fig. 3 should conclude: ". . . and of $\delta X/\delta t$ taken at Borrego, California, U.S.A.". The reference in the text to Fig. 3 should read: "Fig. 3 shows the simultaneous records of $\delta Y/\delta t$ at our base station and of $\delta X/\delta t$ near Borrego Springs . . . ".

CO-ORDINATION CHEMISTRY

THE Fourth International Conference on Co-ordination Chemistry was organized by the Chemical Society and held in London under the sponsorship of the International Union of Pure and Applied Chemistry during April 6–11. Since 141 contributions were received (from twenty-three different countries) in addition to seven invited lectures, it proved necessary to hold three concurrent sessions for the reading of papers. The following report is therefore necessarily based on direct attendance at only a sample of the papers presented and otherwise on the preprinted abstracts.

Prof. K. Ziegler (Mühlheim) in the first of the general lectures began by giving an account of the various steps involved in the catalytic polymerization of olefines by aluminium alkyls and concluded with some remarks on the influence of titanium salts on this reaction. The latter topic was taken up in a paper by G. Natta and G. Mazzanti (Milan), who presented evidence on the structures of some mixed complexes of titanium and aluminium which may be involved. The mechanism of the reaction between aluminium alkyls and titanium halides was further discussed in a paper from Israel.

Dr. H. M. N. H. Irving (Oxford) reviewed the available information on the stability of metal complexes in solution and showed how some simple theoretical ideas could be used to establish useful correlations. Among the many interesting contributions on this topic one may mention a study of thio-complexes from G. Schwarzenbach's laboratory in Zürich, a paper on the heats of formation of ethylenediamine complexes by M. Campolini and co-workers (Palermo), a study of polynuclear copper (II) complexes of carboxylic acids by D. L. Martin and F. J. C. Rossotti (Edinburgh) and work on silver (I)–oxine complexes by D. Dyrssen and collaborators (Stockholm).

Prof. H. Taube (Chicago) reviewed recent work on the mechanisms of complex ion reactions in solution and described some entirely novel experiments of his own. He provided conclusive proof that during the course of the oxidation–reduction reaction between cobalt (III) and chromium (II) ions under appropriate conditions, electrons are transferred through the whole length of the terephthalic acid molecule, and further showed that if the methyl ester of terephthalic acid was present, it was hydrolysed in the course of the reaction. This work opens the way for a full-scale attack on the vexed problem of electron transport through conjugated systems, and should have important consequences.

Studies on the mechanisms of the photochemical reactions of complex ions were reported by S. T. Spees and A. W. Adamson (University of Southern California), who discussed the possible role of doublet states in the photochemistry of chromic complexes; another paper on this subject was given by D. R. Stranks and G. J. Weston (Leeds). Contributions on the detailed kinetics of the hydrolysis of chromic complexes were presented by J. Bjerrum and co-workers (Copenhagen), who infer the existence of the $[\mathrm{Cr\ en_2(enH)\ (H_2O)}]^{4+}$ ion as an intermediate in the hydrolysis of $[\mathrm{Cr(en)_3}]^{3+}$, and by H. L. Schläfer (Frankfurt am Main), who studied the equation of $[\mathrm{Cr\ Ox_2\ en}]^{-}$.

Dr. Greenberg presented the results of some recent studies from the U.S.S.R. on the *trans* effect in the substitution reactions of platinum (II) which suggest that the experimental situation is more complicated than has been previously realized. The first studies of the kinetics of the substitution reactions of *bis*cyclopentadienyl titanium dihalides were reported by A. Jensen and F. Basolo (Northwestern University, Illinois). The exchange reaction of quadridentate complexes, particularly of nickel (II), were discussed by W. W. Fee and B. O. West (Adelaide), and the kinetics of the dissociation of complex cyanides and of ethylene–diamine nickel complexes by G. Emschwiller (Paris) and by A. K. Shamsuddin Ahmed and R. G. Wilkins (Sheffield), respectively.

Some of the liveliest discussions followed papers of a rather theoretical nature dealing with the spectra and magnetic properties of complexes, for example, a paper on the relation between the geometrical structure and the magnetic properties of nickel (II) complexes by G. Maki, and another on the effect of the thiocyanate ion on the spectra of metal ions by C. E. Schäffer (Copenhagen). An interesting account of the magnetic susceptibility of rhenium compounds was given by B. Jezowska-Trzebiatowska (Wroclaw). The variation of the magnetic susceptibility of vanadium (III) complexes with temperature was discussed by B. Figgis, J. Lewis and F. E. Mabbs (University College, London). Two papers, one by S. Minc and W. Libus (Warsaw) and the other by F. A. Cotton and R. H. Holm (Massachusetts Institute of Technology), dealt with the physical properties and relative stabilities of the various types of cobalt (II) complex which exist in solution, and two others, one by C. R. C. Coussmaker and collaborators (Oxford) and the other by A. Turco and G. Giacometti (Padua), considered the properties of the versatile complexes of nickel (II) with substituted phosphines.

The X-ray determination of the structure of a complex formed by azobenzene and arsenic trichloride was reported by E. Ferroni and P. Orioli (Florence); the cuprous–diazoaminobenzene complex was shown by I. D. Brown and J. D. Dunitz (Royal Institution, London) to be dimeric in the crystal and to involve an eight-membered ring containing six nitrogen and two copper atoms. M. R. Truter and her co-workers (Leeds) discussed the structure of β-diketo complexes of trimethyl platinum (IV). Other structures described included those of basic zirconium chromates and β-$\mathrm{Zn(OH)Cl}$. An important paper by I. Linqvist (Uppsala) surveyed the structures of some addition compounds of phosphorus oxychloride and selenium oxychloride.

A further group of contributions dealt with the elucidation of molecular and electronic structure by means of infra-red and Raman spectroscopy. K. Nakamoto, P. J. McCarthy and A. E. Martell (Clark University, Worcester, Mass.) discussed the infra-red spectra of the metal complexes of β-diketones, while D. B. Powell and N. Sheppard (Cambridge) dealt with the metal complexes of amines and ethylenediamine and showed that for the latter both *cis* and *gauche* configurations of the ligand are possible. Infra-red spectra of heteropolytungstates were reported by a group of workers from Moscow. Raman spectra of addition compounds of sulphur trioxide were reported from Amsterdam and of stannic chloride from Karlsruhe.

Among the many papers principally concerned with the preparation of new compounds and the elucidation of their reactions one can pick out only a few. S. Herzog and co-workers (Jena) described the extension of their work on dipyridyl complexes of metals in abnormally low valencies to the preparation of the diamagnetic $[Ti(dipyridyl)_3]^-$ ion; L. Naldini (Milan) described a series of salts of the low-spin (hexa-aryl isocyanide)–manganese (II) complexes; V. Cagliotti and co-workers (Rome) discussed the preparation and reduction of the oxygen adducts of cobalt (II)–histidine complexes.

Carbonyls of iridium (III), *iso*cyanides of rhodium (II) and phosphines of osmium (I) were reported by L. Malatesta and S. Sandroni (Milan), by Miss L. M. Vallarino (Milan) and by L. Vaska (Mellon Institute, Pittsburgh), respectively. Complex fluorides of molybdenum and tungsten and rhenium were discussed by G. B. Hargreaves and R. D. Peacock (Birmingham); R. Hoppe and co-workers (Münster) reported on a variety of zirconium, tin and manganese complex fluorides. Heteropolyacids and related polyanionic compounds were treated extensively by groups from Roumania, the U.S.S.R. and Sweden. The properties of volatile nitrato–iron complexes and copper perchlorates were described by C. C. Addison and N. Logan (Nottingham) and by B. J. Hathaway (Hull), respectively.

The subject most completely covered both in general lectures and contributed papers was that of organo–metallic compounds involving transition metals. Dr. E. O. Fischer (Munich) surveyed experimental work on compounds involving 'sandwich' bonding in a comprehensive and lucid fashion. Prof. R. Nast (Heidelburg) described in detail his important researches on the complex acetylides of the metals; the least stable it appears are spontaneously explosive and the more stable only pyrophoric. Dr. H. W. Sternberg (Pittsburgh) discussed recent experimental work on the reactions of acetylenes, etc., with metal carbonyls and produced some interesting speculations on the relevance of these results to problems both of homogeneous and heterogeneous catalysis. Dr. L. E. Orgel (Cambridge) discussed bonding in zero-valent metal compounds.

Determinations of the crystal structure of some organo–transition metal complexes were reported by A. A. Hock, O. S. Mills and G. Robinson (Manchester); the results were, as usual in this field, very surprising. The infra-red spectrum of chromium dibenzene was described by A. Fritz (Munich). The symmetry of this molecule was discussed at some length. The view of the German school was that theory predicted it to have only three-fold symmetry as argued by E. Ruch (Munich) in a contributed paper. A number of other theoretical chemists (the present author included) held that no definite prediction could be made, but strongly favoured the view that the symmetry would prove to be six-fold. The experimental evidence, it seems, is not yet unambiguous.

A paper by L. S. Meriwether, Marilyn Fiene and G. W. Kennerly established that substitution reactions of a number of nickel carbonyl–phosphine complexes occur by way of a three co-ordinated intermediate rather than by a second-order mechanism. The reactions accompanying the polarographic reduction of iron carbonyls were considered by A. A. Vlček (Prague). There was some discussion of a paper by D. A. Brown (Queen Mary College, London) on the effect of phenyl-substitution on the stability of sandwich compounds.

The preparative work described in the field of acetylene–carbon monoxide chemistry was varied, fascinating, and still largely incomprehensible. G. Natta and co-workers (Milan) discussed the synthesis of succinic acid from carbon monoxide, acetylene and water in the presence of metal carbonyls. They suggested that it required binuclear metal complexes as intermediates and provided good evidence for the occurrence of a peculiar lactone-like derivative of succinic acid as a ligand in certain metal complexes. W. Hübel and E. H. Braye (Brussels) described the numerous new compounds which they have prepared from iron dodecacarbonyl and acetylenes. Some compounds contain aromatic rings, some contain cyclopentadienone, and others cannot at present be formulated in an acceptable fashion (like $C_2H_2Fe_2(CO)_8H_2$, they probably do not have 'acceptable' structures). E. Weiss and W. Hübel described the reactions of cyclopentadienones with metal carbonyls. They demonstrated the ability of cyclopentadienone in certain sandwich compounds to behave more like the anion derived from a phenol than like a normal ketone. Presumably this is due to charge-transfer from the metal to the oxygen of the ring.

The insertion of carbon monoxide into organic molecules by way of metal carbonyls was part of the theme of some of the general lectures. It was discussed in detail for the case of alkyl and acyl manganese carbonyls by T. H. Coffield and co-workers (Ethyl Corporation Laboratories, Detroit), who described some carbon monoxide exchange studies which throw considerable light on the reaction mechanisms involved. L. Kirch and M. Orchin (Cincinnati) described recent experimental work on the oxo-reaction.

Contributions on other metal alkyls included a discussion of the reactivity of the cadmium compounds by J. Vène (Rennes), a paper on alkyl and aryl palladium compounds by G. Calvin, G. E. Coates and P. S. Dixon (Durham), and another on the determination of Grignard reagents by F. G. Mann and I. T. Millar (Cambridge).

A group of papers described catalytic reactions other than those in the carbonyl field. One may mention that of W. Brackman (Royal Dutch Shell, Amsterdam), who described a series of copper–amine complexes which catalyse the oxidation of alcohols, and that of M. T. Beck (Szeged), who described much interesting work on catalysis that has been carried out in Hungary.

Of the papers not directly concerned with metal chemistry I shall mention one, the presidential address of the Chemical Society, which was open to all members of the Congress. Prof. H. J. Emeléus outlined the experimental situation in the field of inorganic polymeric molecules and amply illustrated his thesis that this is a fascinating and largely unexplored region of inorganic chemistry.

The Conference, seen as a whole, left one with no doubt that co-ordination chemistry has entered a period of rapid growth and is already invading fields which traditionally were distinct from it. The development of the various syntheses of large conjugated molecules from carbon monoxide and acetylene can scarcely fail to influence organic chemistry. The close contact between ligand field theory and experiment in the field of co-ordination chemistry provides, perhaps for the first time, a climate in which experiments are designed to test the quantitative predictions of electronic theory; this must prove beneficial to both.

The organization of the Conference, both of the scientific meetings and the more social occasions, was uniformly excellent. All those who were present must be grateful to the members of the Chemical Society committees who were responsible for it and to those industrial concerns which, by their financial support or by acting as hosts, helped to make the meeting so successful.

L. E. ORGEL

THE BRITISH COAL UTILIZATION RESEARCH ASSOCIATION

TWENTY-FIRST ANNIVERSARY OPEN DAYS

THE aim of the Association, from the time of its inception in 1938, has been "to promote research and other scientific work in connexion with the utilization of coal and its derivatives". Some of the achievements of twenty-one years were displayed at the research station during April 22–24.

In 1938, nine experimentalists worked in a single room, 12 ft. square, in Victoria Street, London. To-day the British Coal Utilization Research Association occupies a 20-acre site at Leatherhead, and is one of the largest of the thirty-nine industrial research associations supported by the Department of Scientific and Industrial Research; of its total staff of some 300, eighty are graduates or equivalent and a similar number are research assistants, representative of most of the recognized fields of physical science, from mathematics through the several branches of chemistry and physics to large-scale engineering.

The interests of the Association are many-sided, and this was reflected in the distinctive character of each of the three open days. April 22 was primarily 'members' day'; through its membership the Association forms a link between the four nationalized industries (coal, gas, electricity, transport) and about 150 other members (comprising individual firms and trade associations) which include industrial appliance makers, coal distributors and coal consumers. The Minister of Power, the Right Hon. Lord Mills, was the guest of honour, and in addressing a large and distinguished gathering at luncheon, he observed that the occasion marked the coming-of-age of an Association which had long since established itself as one of the most important and progressive industrial research organizations in Britain.

On the second day the guests were mainly drawn from the field of research; Government departments, research associations, universities and technical colleges were strongly represented. On the morning of the final day parties from local colleges and schools predominated, thus emphasizing the practical interest taken by the British Coal Utilization Research Association in educating young people in the science and technology of coal. In the afternoon the Association was honoured by a visit of a party from the London Section of the Royal Institute of Chemistry; and the day was fittingly concluded by a lecture to this party and other chemists by Prof. R. G. W. Norrish on recent work at Cambridge on flash photolysis in gases.

Throughout its history the British Coal Utilization Research Association has been in close touch with university thought and investigation and has itself maintained a strong programme of basic research. One well-known example of the effectiveness of this approach is the outcome of the experiments on coal breakage which were started in that small overcrowded laboratory in London in 1938. After some years of investigation, in collaboration with the British Colliery Owners Research Association, a specification for grading coal by size was drawn up, and this has been accepted by the National Coal Board as a basis for preparing and marketing coal. Another example of the application of basic research, also exhibited in the Physics Department, was the cone mill. Following a survey of the factors determining the power required for grinding coal to a given size, determination of the Hardgrove grindability index, and measurement of the intrinsic physical and mechanical properties of coal, a matrix theory of coal breakage was developed and the first cone mill was built to test this theory: now its engineering utility is being studied.

Some of the modern techniques being used to investigate both the chemical and the physical aspects of coal constitution were displayed. Research into the chemical basis of the plastic softening of coals, with the view of achieving better control of coking properties, has recently made considerable progress, and current knowledge of the mechanism was illustrated diagrammatically alongside the special apparatus employed. Another exhibit was of interest as the first complete conversion, in a single step, of coal to chemical products without simultaneous production of tar or solid residue: low-rank coals have been treated with chlorine trifluoride, producing a range of chlorofluorocarbons (from colourless oils to resin-like solids) possessing chemical and physical properties that indicate their possible suitability for certain industrial applications.

Considerable work by the Association over a number of years on the ultra-fine porous structure of coal and its development during carbonization has led to the placing, by the U.K. Atomic Energy Authority, of a research contract for fundamental work on the graphite used as moderator in nuclear reactors. This investigation has already shown that closed pores in the graphite become accessible during its reaction with oxidizing gases, and an estimate of the importance of internal burning has been obtained.

Among the current major problems facing the coal industry are: improvement of methods for using small coal; meeting the challenge of competition from oil; and assistance in the implementation of the Clean Air Act. Research by the Association has, therefore, been directed especially towards: (*a*) improving and devising appliances suitable for burning small coal; (*b*) developing methods for the automatic control of combustion; and (*c*) investigations on reduction of atmospheric pollution from coal-burning appliances.

One of the most important current needs is a method of converting small coal cheaply to gas, and ultimately to oil. The Association's experimental slagging gasifier, built under contract with the Ministry of Power, at present consumes about a ton of fuel an hour and can take, in short tests, up to half of this in the form of pulverized coal. It has been operated successfully at various ash-levels and over a range of ash fluidities. Background studies have made possible the tentative correlation of slag viscosity–temperature curves with slag composition ; and improved methods of analysis have enabled the important constituents of ash to be determined at the rate of four samples a day.

The automatically controlled small-pipe, forced-circulation central heating system, developed by the Association, is being actively promoted by the Coal Utilization Council, and was displayed by them in the exhibition they had arranged on the site. Also on view in the Council's exhibition were some of the thirty or more designs of free-standing convector fire with restricted throat, a type of appliance that has been developed by the British Coal Utilization Research Association.

The Association's Calorimeter Room has taken its place as an absolute standard for testing domestic appliances. A method of automatic control for miniature chain-grate stokers, used to fire central-heating boilers (½–2 million B.T.U./hr.) in offices or blocks of flats, has been devised, and a unit burning ½-in. small coal smokelessly and at high efficiency is now being tested.

An air–fuel ratio controller has been developed within the Association for fitting to stokers of Economic and Lancashire boilers in order to take much of the responsibility for maintaining the correct ratio of fuel to air out of the hands of the fireman, and one of these controllers was in use on the boiler used for site heating.

A first step towards finding means for reducing atmospheric pollution from coal-burning appliances has been made through the work on the measurement of dust and grit emission from boiler furnaces. The methods of sampling dust from stacks developed by the Association were on view and have aroused much interest in those concerned with enforcing or complying with the Clean Air Act. The automatic particle-sizing apparatus developed by the Association was displayed ; with special care it can be employed down to 2 microns and can be used to carry out eight analyses a day.

The study of problems arising from the deposition of inorganic solids and corrosive liquids from flue gases in water-tube boilers forms an important part of the Association's work ; these problems are investigated both in the laboratory and at power stations. Large- and small-scale equipment used in these investigations was on view. Special measuring apparatus devised for this work was also demonstrated.

It has not been possible in this short account to mention more than a selection of the exhibits. A fuller account of the current researches is contained in the annual report of the British Coal Utilization Research Association for 1958, and a bibliography of the Association's publications during 1938–59 is to be published in the near future.

THE EAR UNDER WATER

A DISCUSSION meeting devoted to "The Ear under Water" was held at the Royal Society on March 12. In his opening survey, Prof. O. Lowenstein pointed to the fact that even in its most highly evolved state the vertebrate ear is a dual—or even triple—purpose sense organ. It incorporates receptors for angular acceleration (semicircular canals), for linear acceleration including gravitational stimuli (otolith organs) and for oscillatory changes in linear acceleration such as vibration in general and sound in particular (otolith organs, cochlea). The vertebrate ear appears to be a phylogenetic novelty derived by modification from the lateral-line organs of early fish-like vertebrates and not from the statocyst of the invertebrates. Thus, the ear is probably not the comparative-anatomical homologue of the invertebrate statocyst. There is no doubt, however, that the two organs are functionally analogous. It was therefore considered desirable to review recent work on the invertebrate statocyst in the context of the symposium.

Dr. Melvin Cohen (University of Oregon) described the anatomy of the statocyst of the lobster, *Homarus americanus*, and discussed the results of an electrophysiological analysis of its function. It contains two types of position receptors, one for the monitoring of absolute position and one which also indicates the direction from which a certain position is approached. A third receptor type functions as an acceleration receptor and is insensitive to position. There are receptors responding to vibration of the solid substrate, but no reactions to air- or water-borne sound could be registered. Dr. Cohen pointed to the striking similarities between the responses from the crustacean statocyst and those from the various end organs of the vertebrate labyrinth.

In a paper on the cephalopod statocyst, Prof. J. Z. Young gave a detailed description of the morphology of the statocyst of the octopus. This remarkable sense organ, too, shows a most interesting and functionally suggestive number of items of structural convergence with the vertebrate labyrinth. Apart from a vertically placed macula with otolith, there is a crista which has sections in three planes of space, each section being associated with a separate nerve. The sensory hairs are ensheathed in a matrix of unknown composition forming cupulæ reminiscent of those found in the labyrinth. Large neurons having dentritic endings as well as hair processes underlie the sensory cells of the crista and appear to make synaptic contact with them, although the hair cells themselves are primary sensory cells equipped with centripetal axons. A hand-shaped vane (the so-called anti-crista) protrudes into the endolymphatic space and seems to be so arranged as to protect the vertical section of the crista from overstimulation when the octopus suddenly accelerates forward, as it does on attacking prey.

Prof. Young stressed that there is no behavioural evidence of hearing in the cephalopods, but on anatomical grounds there is no reason why the cephalopod statocyst should not be potentially capable of vibration reception or even hearing, besides its manifestly obvious function as an organ of static and dynamic spatial orientation.

The vertebrate ear evolved in aquatic animals, and it may well be that its function as a vibration receptor evolved simultaneously with that of an organ of orientation. As an introduction to the problems connected with hearing in aquatic vertebrates, Dr. P. Vigoureux (National Physical Laboratory, Teddington) gave a most useful survey of the physical aspects of sound propagation under water. So far as penetration of sound from air into water is concerned, there is a critical angle of 13° of reflexion at the interface between air and water, and total reflexion occurs at all greater angles of incidence. Sound can therefore penetrate into water only if its incidence is almost vertical. Yet the human ear is sensitive enough to hear under-water sound from a powerful source in the air overhead. Dr. Vigoureux also discussed some effects of temperature gradients leading to conditions of exceptionally good sound propagation over long distances. Sound absorption is only 1/1000th part of what it is in air, and this is yet another reason for the considerably greater distance of sound propagation in water.

Prof. S. Dijkgraaf (Utrecht) introduced his account of hearing in bony fishes by a definition of sound and hearing. This has for a long time been a controversial matter and he advocated ascription of the ability of hearing to such animals as are sensitive to a succession of pressure waves propagated with a characteristic velocity through the medium, be it air or water, and able to detect these stimuli by means of special receptors exclusively used for this purpose. If the latter condition is not fulfilled, one should speak of sound- or vibration-reception instead of hearing.

Prof. Dijkgraaf distinguished among the bony fishes between what he called 'specialists' and the normal run of fishes. The 'specialists', mostly fresh-water fishes, have been shown to possess sound-reinforcing structures like the Weberian ossicles or special gas chambers connected with the ear. Their frequency-range is considerable and they are more highly sensitive to tones than man up to a frequency of 1,000 c./s. They are also capable of pitch discrimination over a limited range (up to 1,260 c./s.) and can discriminate frequency differences as low as 4 per cent. However, no evidence for directional hearing has so far been obtained. So-called normal fishes (almost all marine forms) have an upper limit of 400–1,000 c./s. and a much higher threshold.

In the second part of his paper, Prof. Dijkgraaf dealt with the problem of functional localization of hearing within the labyrinth of bony fishes and discussed the part played by the otolith organs in the sacculus and lagena in some, and the probable role of the utriculus in other forms, depending on differences in the nature and topographic deployment of the sound-reinforcing structures. Tactile skin receptors may be involved in the reception of low-frequency sound, but there is no evidence for the collaboration of the lateral line.

In higher vertebrates the ear became adapted to the reception of airborne sound. The special matching devices of the middle ear and the range-finding pinna of the mammals were evolved. Papers by Dr. Reysenbach de Haan (Eindhoven) on aspects of mammalian hearing under water and by Dr. F. C. Fraser and Mr. P. E. Purves of the British Museum on the osteology, acoustic matching, and evolution of air sinuses, and on muscular and vascular arrangements, acoustic isolation, and directionality of hearing, dealt with the way in which the Cetacea solved the problems of underwater hearing on their return to a fully aquatic existence.

Dr. Reysenbach de Haan pointed out that under water the external ear and the middle ear of the terrestrial mammal become useless. Man has no directional hearing under water and suffers a loss in hearing of 60 db. Whales and dolphins rely chiefly on sound for their orientation, and yet they have no outer ears and their auditory meatus has become highly modified. Dr. Reysenbach de Haan believes that the modified structures corresponding to the meatus are devoid of function, as the rate of transmission of sound in the tissues around the external auditory canal is practically equal to that in water. The bulla, however, is filled with air and kept hermetically sealed from the water outside. The striking feature of the middle ear or bulla is that it has parted company with the skull and, like the inner ear in the petromastoid, has come to hang loose under the skull. Foam-filled sinuses in the petromastoid are in communication with the air of the middle ear in the bulla and via the Eustachian tube with the air of the respiratory passages. The inner ear is thus completely air-insulated from the surrounding tissues, from the skull, and from the surrounding water. The two ears are also completely insulated from one another. This, Dr. Reysenbach de Haan held, was an indispensable condition for successful directional hearing under water.

Modifications of the middle ear and also of the cochlear structures were demonstrated to be associated with the sensitivity of the Cetacea to supersonic frequencies higher than 100,000 c./s. Cetaceans produce high-pitched sound and are known to echolocate like bats. In water, with the four times longer wave-length, much higher frequencies are necessary for the detection of objects of the same size.

Experiments on the directional hearing of dolphins and the methods used in the capture of these animals in Danish waters and their transport to the Netherlands were illustrated by a film made by W. H. Dudok Van Heel (Holland).

In their communication on the anatomy and function of the cetacean ear, Dr. F. C. Fraser and Mr. P. E. Purves, of the British Museum of Natural History, dealt with the morphology of the auditory meatus in toothed whales and whalebone whales. They have come to the conclusion, contrary to the opinion voiced by Dr. Reysenbach de Haan, that the meatus is not devoid of function. They believe that it plays an important part in sound conduction.

Experiments on a large portion of the squamomastoid region of a fin whale, preserved by deep-freezing and dissected after thawing to expose the middle ear, the wax plug and meatus, showed that the attenuation of high-frequency sound waves (100,000 c./s.) was considerably lower when conduction followed the meatus with its lengthwise orientated fibre system, than in the surrounding tissues in which the fibrous structures are randomly orientated. The authors assumed that sound transmitted by the meatal path would be dominant at any level of intensity. The animal must be subjected to an intensity and/or phase difference at the cochleæ of the two ears due to the screening effect of the head and the distance separating the two meatal openings. This may be of vital importance for directional hearing.

A detailed description of the air sinuses and peculiarities of the vascular system served to emphasize the acoustic isolation of ear from skull and jaws and ear from ear. The part played by the albuminous foam formed by nitrogen in an oil–mucus emulsion was discussed, and it was shown how this foam can remain persistent even during a prolonged dive.

Finally the modifications of the middle ear ossicles were described with reference to the requirement for successful matching of the cetacean ear to water-borne sound. They were illustrated by a working model.

A series of anatomical exhibits was shown to illustrate the specialization in the topographic relationship between ear and skull, especially the arrangement of air sinuses in the various cetaceans.

The contributions to the symposium will be published in full in the *Proceedings of the Royal Society*.

O. LOWENSTEIN

THE INDIAN ASSOCIATION FOR THE CULTIVATION OF SCIENCE

THE annual report for 1957–58 of the Indian Association for the Cultivation of Science*, which includes lists of papers published during the year under their departmental headings, records further work on the thermal diffusion and inter-diffusion of gases. An apparatus has been designed for measuring the thermal conductivity of diffusing gases and a new apparatus constructed for purifying high-pressure commercial hydrogen. The dimensions of the unit cell of naphthazarin have been re-determined by X-ray methods and further work on the molecular structure of this crystal is in progress. The work of the Department of Magnetism was reorganized and the study of paramagnetic anisotropy of dihalides of copper(II), the paramagnetic behaviour of fluosilicates and chlorostannates of copper(II) and measurement of the principal susceptibilities of paramagnetic crystals down to liquid-hydrogen temperatures has been undertaken, as well as the study of paramagnetic crystals both by the paramagnetic electron resonance and the proton resonance method. The anisotropy of many nickel(II) salts of similar constitution was studied to ascertain the effect of long-range crystalline fields in these salts, and work on paramagnetic alums of titanium(III), vanadium(III) and chromium(III) was completed.

In the Optics Department the Raman spectra of *o*-chlorophenol in different solvents, of α- and γ-picoline and their solutions in alcohol in liquid and solid state, and of ethylbenzene, chlorobenzene and bromobenzene in the frozen state at − 180° C. have been determined and the ultra-violet absorption spectra of many aromatic compounds studied in the vapour, liquid and solid states, as well as those of frozen 0·2 per cent and 25 per cent solutions of the dichlorobenzenes in *iso*-butyl alcohol at − 180° C. and the Debye–Scherrer patterns due to frozen toluene, chlorobenzene and bromobenzene and to diphenyl at 32° C. and at − 180° C. The Department of Theoretical Physics was concerned mainly with the spin of an electron from five-dimensional wave equations, the influence of constant electric and magnetic fields on the spin of the particle, electronic energy bonds in lattices and some generalizations in relativistic cosmology.

In the Department of Physical Chemistry, investigations in high polymer chemistry related to the kinetics and chain transfer behaviour of methyl *iso*propenyl ketone, the aqueous polymerization of vinyl monomers in redox systems, the thermodynamic properties of binary mixtures, the determination of absolute values of the rate constants in polymerization and the preparation and properties of soil conditions of the krillium type. In general and analytical chemistry, work is being carried out on the mutual solubilization of oils and water, the decomposition of peroxides in different solvents and the velocity of ultrasonic waves in solutions and liquids. An apparatus has been assembled for determining the mutual solubilities of organic compounds *in situ*. The Department of Organic Chemistry continued its investigations on sesquiterpenoids, diterpenoids, triterpenoids and steroids, and in the Department of Inorganic Chemistry attention was concentrated on the study of co-ordination complexes and their applications in analytical chemistry. It has been shown that 3- and 5-oximinomethylsalicylic acids and 3- and 5-aldehydosalicylic acids can be used for estimating thorium and its separation from the cerite earths.

THE EAST AFRICAN INDUSTRIAL RESEARCH ORGANIZATION

REPORT FOR 1957–58

THE annual report for 1957–58 of the East African Industrial Research Organization* records the official opening of the new headquarters of the Organization in Nairobi on February 14, 1958, and spectacular results from a close collaborative study by the Fuel Advisory Service with the Research and Economy Section of the Chief Mechanical Engineer's Department of the East African Railways and Harbours, notably in the design of a special burner for lighting up locomotive boilers and in increasing the power developed by locomotive engines in service, using a Giesil ejector. Advice was also given on the utilization of wood waste, and fuel economies of 5–20 per cent were demonstrated in some thirty factories. An oil-fired incinerator was designed for the new swine fever research centre at Mugaga and a similar but larger one for the new Wellcome Foot-and-Mouth Disease Centre.

The Department of Fuel Technology and Chemical Engineering has also examined the use of solar driers and the dust-proofing of motor cars. Extensive work on the mechanical drying of Arabicz coffee has shown that damage is reduced by pre-drying and increased by increasing the final drying temperatures, and that daylight has a marked effect on the liquoring quality of the dried bean. The range of light frequencies responsible is now being studied, and apparatus has been constructed for the determination of moisture content and desorption isotherms using a wet- and dry-bulb technique with recirculated air flow. Two full-scale driers for use on wet groundnuts were designed and tested for the National Institute of Agricultural Engineering and the Tanganyika Agricultural Corporation.

---

* East Africa High Commission. East African Industrial Research Organization Annual Report, 1957–1958. Pp. ii+18. (Nairobi: Government Printer, 1958.) Sh. 2.

Work on the production of vitreous bowls should now permit costs of production to be estimated. Successful large-scale trials of locally made refractory bricks and bonding cement for setting them in locomotive fire-boxes are reported. Much work was done on the elimination of arsenic from cement copper prepared from an ore containing arsenic and on the production of high-grade silicophosphatic fertilizer by the low-soda process.

PART-TIME WORK FOR WOMEN GRADUATES

IN 1956, as an experiment, an agency was started in the London area to put women graduates in touch with any suitable part-time work. From the beginning it was hoped that the agency might not only help to canalize existing opportunities but also increase them. Many potential employers are prejudiced against part-time workers; it was felt that they might have more confidence if they could interview not one but a number of suitable candidates for each vacancy, and feel that they could call on a reserve if the need arose.

Some types of work, such as highly responsible administrative posts, could not be adapted to part-time hours, but other types could: teaching, research assistance, information work, indexing, cataloguing, translation, abstracting, statistical work all seemed possible to arrange in this way. It also seemed clear that much of this work could be done at home and that it would be greatly welcomed, especially by mothers of young children. The growth of the agency has recently been described by Mrs. D. D. Furley (*Univ. Rev.*, 31, No. 2; February 1959).

The agency started in a modest way with a nucleus of about twenty graduates in London who were in search of part-time work. At first, few vacancies were notified to the agency. After the appearance of one or two letters to the Press from people who had heard of the scheme, about three hundred graduates registered as potential part-time workers in the London area and letters were received from about five hundred others living outside the London area who were seeking work, but did not realize that the scheme applied only to London.

Many employers were sympathetic to the idea and more jobs gradually became available.

In the first eighteen months, 378 jobs were notified to the agency, and 260 of them were filled by graduates registered with it. In the following twelve months, 440 jobs were notified, and 303 were filled. The majority of these jobs were in teaching, research of one kind or another and editorial or secretarial work. The figures included both temporary and permanent jobs; several women who started by filling some temporary vacancy have later been found permanent part-time jobs by the same employer.

It is impossible to fill some of the vacancies notified to the agency. There are many reasons: part-time science teachers are as rare as full-time ones; there is more demand than supply for good secretaries; the pay offered is sometimes, and particularly in social work, unattractive; and vacancies are often separated from the likeliest candidates by a journey of impossible complexity and length.

Fewer permanent than temporary jobs are filled. This seems to reflect a general reluctance on the part of married women to commit themselves to permanent work. Women who have not held a job since marriage or since having children are sometimes uncertain how it will work out. Mothers are always reluctant to commit themselves to working during school holidays and permanent jobs which conform to school holidays are very hard to find.

In May 1957 a similar agency was opened in Manchester. Although similar to the London agency, in one way it differs from it. As Manchester is a smaller and non-metropolitan city, it was thought advisable not to confine the agency to graduates, but to use it for other women with comparable qualifications—diplomas, teachers' training certificates, or knowledge of foreign languages. Eighteen months experience in Manchester bear out the findings of the London agency.

Altogether, more than a thousand women, about 800 of them married, have registered with the London agency since its inception. Although about 40 per cent of them have been 'housebound' by children, illness or elderly relatives, approximately half of them have found work through the agency. In Manchester more than one hundred women have registered, all but nine of whom are married; sixty of these have a university degree, twenty-three a diploma of one kind or another. Forty-six of these have found temporary or permanent work through the agency.

MIGRATION AND DISPERSAL OF NEW ZEALAND GANNETS

A TOTAL of 3,999 gannet chicks was banded at Plateau station, Cape Kidnappers, Hawke's Bay, and Horuhoru station, Hauraki Gulf, New Zealand, between 1951 and 1957. Up to March 31, 1957, 207 recoveries were made. These recoveries include 26 chicks which had not left the gannetry, 146 birds recovered outside the gannetry, and 35 live sub-adult birds caught on their return to Plateau gannetry. An account of the investigation has been given by Kazimierz Wodzicki and Peter Stein (*Emu*, 58, Part 4; September 1958).

The percentage of recovery for the whole period was 3·1 (3·3 from Plateau and 2·9 from Horuhoru). This distribution of recoveries throughout the year shows two periods of increased mortality; one affecting first-year birds within the first few months of their independent life and associated with the crossing of the Tasman Sea; another peak occurring in late spring and summer and comprising one- to two-year-old birds.

It was found that fully fledged chicks leave the gannetry at the age of 15½ weeks. The majority of Plateau gannets take a northern route towards the North Cape; others migrate along the eastern coast of North Island and reach Australia through Cook Strait. Recoveries of Horuhoru gannets show an almost exclusive use of the northern route. At the age of 24 weeks all but sickly or late chicks cross the Tasman Sea with an average speed of up to 240 miles a day.

In Australia young gannets disperse widely from subtropical waters in the south and to the Indian Ocean pelagic waters in the west. Horuhoru birds tend to go further south than those banded at Plateau. There seems to be no appreciable difference in geographical distribution among various age-groups of the sample. Sub-adult gannets remain in Australian waters until they are two to three years old.

From that time an increasing number of recoveries is made in New Zealand, where the birds disperse around the coast, and there appears to be some difference in the geographical distribution of recoveries from the two stations.

An analysis of live birds recovered at the gannetry shows that young gannets begin to reappear at their home-gannetry at the age of three years, first as 'roosting' or 'unemployed' birds; from the age of 4–5 years they commence to breed, but at the age of 6–7 years only about half of the birds are breeding.

In all three subspecies of the gannet there is a similar strong urge in juvenile birds to migrate to warmer seas; a similar maximum distance of about 4,000 miles may be flown by the three subspecies, but whereas North Atlantic and Cape gannets move towards the equator, New Zealand-bred Australasian gannets migrate westwards.

BIOSYNTHESIS OF CELL CONSTITUENTS FROM C_2-COMPOUNDS

Formation of Malate from Glycollate by *Pseudomonas ovalis* Chester

DURING the growth of micro-organisms, intermediates of the tricarboxylic acid cycle are utilized to provide the carbon skeletons of many cell constituents[1,2]. When C_2-compounds are the sole source of carbon, means must exist whereby such intermediates, drained from the cycle, are replenished by ancillary reactions. When the C_2-substrate for growth is acetate, this is accomplished via the glyoxylate cycle[3–5], in which the decarboxylative steps of the tricarboxylic acid cycle are replaced by the overall reaction:

$$\text{acetate} + iso\text{citrate} \rightarrow \text{succinate} + \text{malate} \qquad (1)$$

Reaction (1) is the sum of two reactions, catalysed respectively by *iso*citratase[6,7] and by malate synthetase[8]. Experiments on the influence of growth substrates on the formation of *iso*citratase[9] have shown, however, that this enzyme is formed only when acetate or a precursor of acetate (such as octanoate[10]) serves as growth substrate, and that cells grown on C_2-compounds other than acetate (such as glycollate, glycine or oxalate) contain only negligibly low amounts of *iso*citratase. Other routes must therefore exist for the necessary syntheses of tricarboxylic acid cycle intermediates from these C_2-compounds.

The purpose of this communication is to show that cells grown on glycollate contain enzymes capable of forming malate from glycollate, and to suggest a possible route (Fig. 1) for the formation of cell constituents from glycollate. The evidence for this suggestion rests on the following observations:

(1) Washed suspensions of *Pseudomonas ovalis* Chester grown on glycollate readily oxidized glycollate, glyoxylate, pyruvate and all intermediates of the tricarboxylic acid cycle, indicating the occurrence of that cycle under these conditions.

(2) Extracts of such cells, obtained by supersonic disintegration and centrifugation, readily catalysed the formation of glyoxylate from glycollate. Fractionation of such extracts with ammonium sulphate indicated that this enzyme, which catalysed the reaction:

$$\text{glycollate} + A \rightarrow \text{glyoxylate} + A.2\text{H} \qquad (2)$$

where A is an unknown electron acceptor, was largely concentrated in that fraction precipitable between 0 and 35 per cent saturation with ammonium sulphate. The bright yellow colour of this fraction, and the finding that its ability to oxidize glycollate was enhanced by the addition of phenazine methosulphate (0·1 per cent w/v), suggest that reaction (2) may be catalysed by a glycollic oxidase, possibly similar to that described in spinach leaves[11], in which case the electron acceptor A would be a flavoprotein.

(3) When glyoxylate was incubated anaerobically with crude sonic extracts of cells grown in glycollate, carbon dioxide was rapidly evolved. In order to establish the stoichiometry of this reaction, the crude extracts were fractionated with ammonium sulphate (35–50 per cent saturation), dialysed, and eluted from columns of diethylaminoethyl cellulose with portions of phosphate buffer, pH 7·5, of increasing strength. When the fraction eluted by 0·1 M buffer was incubated with 6·7 μmoles of glyoxylate, 3·4 μmoles of carbon dioxide were evolved; this is quantitatively in agreement with the following reaction:

$$2\ \text{glyoxylate} \rightarrow CO_2 + C_3\text{-compound} \qquad (3)$$

observed by Krakow and Barkulis[12] with extracts of *E. coli* grown in glycollate. As described by these authors, maximal enzymic activity depended on the presence of magnesium ions and thiamine pyrophosphate.

(4) This purified cell fraction also catalysed the oxidation of reduced diphosphopyridine nucleotide in a reaction dependent on the presence of glyoxylate and enhanced by the addition of magnesium ions and thiamine pyrophosphate. The rate of oxidation of reduced diphosphopyridine nucleotide increased with time, and was more rapid after pre-incubation of the cell fraction with glyoxylate, magnesium ions and thiamine pyrophosphate than when it was present from the start. This suggested that the

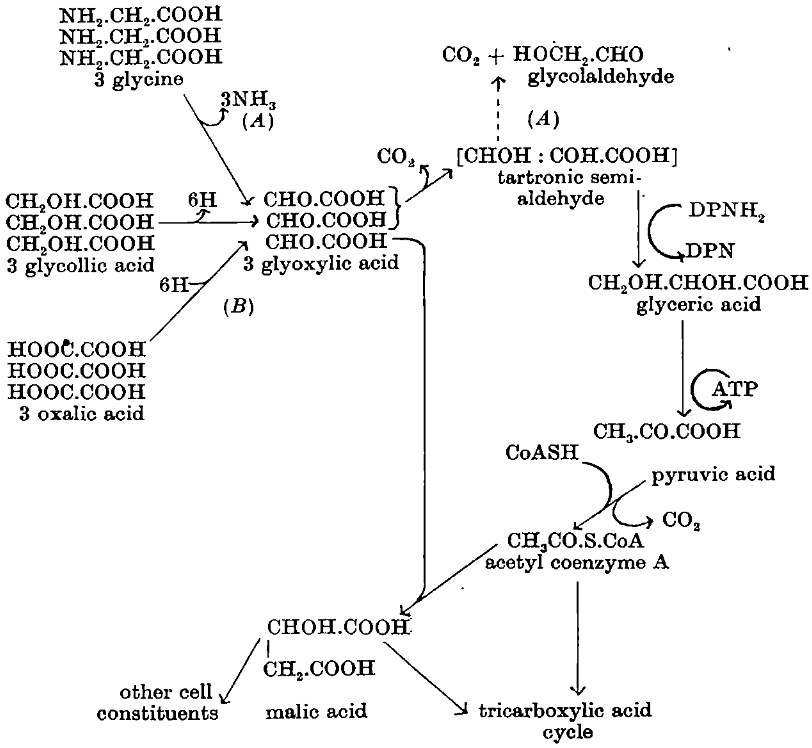

Fig. 1. Possible route for the formation of cell constituents from C_2-compounds by *Pseudomonas*
($DPNH_2$ = reduced diphosphopyridine nucleotide; ATP = adenosine triphosphate; CoASH = coenzyme A)
(*A*) see Callely and Dagley (second communication); (*B*) see Quayle and Keech (third communication)

compound reduced by reduced diphosphopyridine nucleotide was not glyoxylate, but a material derived from glyoxylate.

(5) In the presence of thiamine pyrophosphate and excess reduced diphosphopyridine nucleotide, the purified cell fraction catalysed the formation of 1·8 μmoles of glyceric acid for the utilization of 3·5 μmoles of glyoxylate. No glyceric acid was formed when reduced diphosphopyridine nucleotide or glyoxylate was omitted, or when the cell fraction was boiled prior to incubation.

(6) In the absence of reduced diphosphopyridine nucleotide, the purified cell fraction catalysed the conversion of [1-^{14}C] glyoxylate to carbon-14 dioxide and an unknown material, which was capable of reacting with acid 2,4-dinitrophenylhydrazine to form a radioactive derivative. On addition of alkali, this derivative lost most of its radioactivity and gave a spectrum indistinguishable from that of the *bis*-2 : 4-dinitrophenylhydrazone of glyoxal (max. light absorption at 570 mμ). In the presence of reduced diphosphopyridine nucleotide, this unknown material did not accumulate; instead, 1 molecule of radioactive glycerate was formed for each molecule of carbon-14 dioxide evolved and for each 2 molecules of [1-^{14}C] glyoxylate utilized. No labelled glycollate was found, which showed that glyoxylic reductases[13,14] were absent from this cell fraction.

(7) The incorporation of label from [1-^{14}C] glyoxylate into glycerate by the purified cell fraction was not affected by addition of hydroxypyruvate, and the hydroxypyruvate re-isolated after the incubation was devoid of radioactivity. The purified cell extract did not catalyse the oxidation of reduced diphosphopyridine nucleotide in the presence of hydroxypyruvate.

These results indicate that the overall process occurring was the formation of a C_3-compound from glyoxylate by reaction (3), followed by its reduction to glycerate:

$$C_3\text{-compound} + DPNH_2 \rightarrow \text{glycerate} + DPN \quad (4)$$

They further show that, unlike the system described by Krakow and Barkulis[12], the C_3-compound formed by *Pseudomonas* extracts was neither hydroxypyruvate nor any material in ready equilibrium with it. It is conceivable that the unknown C_3-compound is tartronic semialdehyde[15], the ene-diol form of which[16] (HCOH : COH.COOH) might exhibit the properties noted under sections (4)–(7) above.

(8) Crude sonic extracts of cells grown in glycollate formed carbon-14 dioxide and radioactive glycerate from [1-^{14}C] glycollate, this being the sum of reactions (2)–(4).

(9) Crude extracts of cells grown in glycollate prepared in a Hughes press[17] catalysed the formation of pyruvate from glycerate when incubated with adenosine triphosphate, but not when adenosine triphosphate or glycerate was omitted or when the cell extract was boiled prior to incubation.

(10) Crude sonic extracts of cells grown in glycollate readily oxidized pyruvate, presumably via acetyl coenzyme A. Such extracts also contained high activities of malate synthetase[8] and were capable of forming[18] about 7 μmoles of malate/hr./mgm. of protein from acetyl coenzyme A and glyoxylate, as measured by optical assay[19].

Reactions (2)–(4), in conjunction with the reactions leading from glycerate via pyruvate to acetyl coenzyme A, would represent the conversion of two molecules of glycollate to one of acetyl coenzyme A and two of carbon dioxide. Condensation of the acetyl coenzyme A thus formed with one molecule of glyoxylate (derived from the oxidation of a third molecule of glycollate) would yield one molecule of malate:

$$3\ \text{glycollate} \rightarrow \text{malate} + 2\ CO_2 + 6\ H \quad (5)$$

which would serve as the required precursor of cell constituents. The findings described by Callely and Dagley and by Quayle and Keech in the communications following indicate that this or closely similar biosynthetic routes may operate also in pseudomonads grown on glycine or oxalate as sole carbon sources.

Full experimental details of this work will be published elsewhere.

We wish to thank Sir Hans Krebs for his interest and encouragement, and Prof. F. Dickens for gifts of Li hydroxypyruvate. This work was supported in part by the Rockefeller Foundation and by the

Office of Scientific Research of the Air Research and Development Command, U.S. Air Force, through its European Office, under Contract No. AF 61(052)-180.

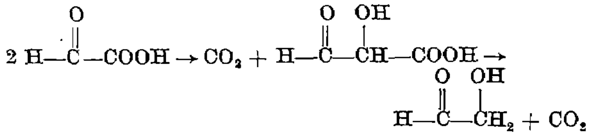
Metabolism of Glycine by a Pseudomonad

Bachrach[1] isolated from the deep litter of a poultry house four species of *Pseudomonas* that utilized uric acid as sole source of carbon and nitrogen for growth. Prof. B. C. J. G. Knight kindly made these strains available, and we have studied the metabolism of glyoxylic acid by '*Pseudomonas A*' grown with glycine as sole source of carbon in aerated mineral salts media at 30° C. Whole cells oxidized various acids of the tricarboxylic acid cycle; and although citrate was attacked only slowly, this may be attributed to slow penetration of the cells by the compound, which was oxidized by cell-free extracts. Glyoxylic acid was oxidized rapidly by cells grown with glycine, but not with succinate as source of carbon. The work of Janke and Tayenthal[2] and Campbell[3] has established glyoxylate as an intermediate in glycine metabolism by species of *Pseudomonas*.

Extracts of cells grown with glycine catalysed the decarboxylation of glyoxylic acid. After disintegration in a Hughes press[4] cooled to −14° C., each 10 gm. of crushed cells was homogenized with 1 gm. of powdered alumina and 25 ml. of phosphate buffer, *p*H 7·2; cell debris and alumina were then removed by centrifuging to give a clear yellowish extract. Manometer flasks filled with nitrogen and fitted with two side-arms contained different amounts of glyoxylic acid (3–17 μmoles) to which 0·5 ml. of extract was added at 30° C. The carbon dioxide released after tipping 0·5 ml. of 3 *N* sulphuric acid from the second side-arm was about 85 per cent of that calculated on the assumption that one mole of glyoxylate gave rise to one mole of gas. Extracts did not oxidize glyoxylate: the same amounts of carbon dioxide were evolved in air as in nitrogen; and no glyoxylate or other keto-acid remained when all gas had been released. The reaction was also conveniently studied by following the rate of disappearance of glyoxylate, determined by the method of Friedemann and Haugen[5]; thus, from 10 ml. of reaction mixture in a boiling-tube at 30° C., 15–20 μmoles of glyoxylate were lost in 10 min. in the presence of 1 ml. of fresh extract. After reaction, the solution contained a compound which formed a derivative with 2 : 4-dinitrophenylhydrazine giving a purple colour with 5 *N* sodium hydroxide; the absorption spectrum showed a maximum at 565 mμ and appeared identical with that of the *bis*-2 : 4-dinitrophenylhydrazone of glycolaldehyde (and glyoxal). The product of glyoxylate decarboxylation reacted with naphtharesorcinol in 23 *N* sulphuric acid to give a green colour; the absorption spectrum was similar to that recorded by Dickens and Williamson[6] for hydroxypyruvate and glycolaldehyde; and calculations based on the extinction coefficient at 660 mμ showed that one mole of glycolaldehyde would be formed from two moles of glyoxylic acid.

By analogy with the reactions[7] for the conversion of pyruvate to acetoin, with β-acetolactic acid as intermediate, the decomposition of glyoxylate may be formulated as follows:



$$2\,H{-}\overset{\overset{\displaystyle O}{\|}}{C}{-}COOH \rightarrow CO_2 + H{-}\overset{\overset{\displaystyle O}{\|}}{C}{-}\overset{\overset{\displaystyle OH}{|}}{C}H{-}COOH \rightarrow H{-}\overset{\overset{\displaystyle O}{\|}}{C}{-}\overset{\overset{\displaystyle OH}{|}}{C}H_2 + CO_2$$

We have not yet succeeded in separating these two enzymes, and our evidence, which is discussed below, for an intermediate step in the formation of glycolaldehyde is therefore indirect.

When extracts (5 ml.) were dialysed against phosphate buffer (4 lit.) for 24 hr. with stirring decarboxylation of glyoxylic acid was catalysed only when thiamine pyrophosphate and magnesium ions (each 1·5 μmole per ml.) were added with extract. Crude extracts catalysed the rapid oxidation of reduced diphosphopyridine nucleotide in the presence of glyoxylate, but this occurred only very slowly after dialysis. When thiamine pyrophosphate and magnesium were added, rapid oxidation of reduced diphosphopyridine nucleotide was restored, as shown in Fig. 1; however, this oxidation was not catalysed when glycolaldehyde was substituted for glyoxylate. Accordingly, it appears that the immediate product of glyoxylate decarboxylation, which we suggest is tartronic semialdehyde, is the acceptor of hydrogen from reduced diphosphopyridine nucleotide; the reduction product would be glyceric acid, although firm identification is hindered by the competing reaction which produces glycolaldehyde. Oxidation of reduced diphosphopyridine nucleotide in the presence of extract was much more rapid with presumed tartronic semialdehyde present than with hydroxypyruvate, which has also been suggested as a product of glyoxylate decarboxylation by *E. coli*[8].

Since it serves as a substrate for transketolase[9], the production of glycolaldehyde by the reactions described may be of significance in relation to carbohydrate synthesis by this organism; but since glycolaldehyde is itself a C_2-compound, *net* synthesis of cell constituents must be accomplished by a reaction sequence such as that proposed by Kornberg and Gotto (first communication), in which pyruvate malate and other tricarboxylic acid cycle compounds are formed. Support for a reaction sequence involving pyruvic acid was given by experiments with whole cells. When harvested from a glycine medium after

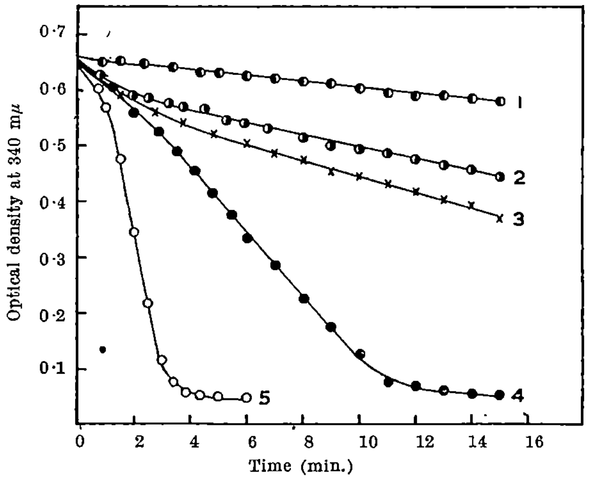


Fig. 1. Oxidation of reduced diphosphopyridine nucleotide by dialysed extracts of '*Pseudomonas A*' grown with glycine. The reaction was started by addition of 0·1 ml. of extract and followed by the fall in optical density at 340 mμ in mixtures made up to a total volume of 3·3 ml. with phosphate buffer (0·015 *M*, *p*H 7·2). Where stated, the following were added: reduced diphosphopyridine nucleotide, about 0·36 μmole; glyoxylic acid, 10 μmoles; thiamine pyrophosphate, 4 μmoles; magnesium sulphate, 5 μmoles. (1) Thiamine pyrophosphate and magnesium ions; no glyoxylate; (2) glyoxylate only; (3) glyoxylate and magnesium ions; (4) glyoxylate and thiamine pyrophosphate; (5) complete reaction mixture of glyoxylate, thiamine pyrophosphate and magnesium ions

about 18 hr. in the stationary phase, a lag in growth of 4 hr. occurred when suspensions were aerated in fresh glycine + mineral salts medium. During this time a keto-acid accumulated of which the spectrum of the 2 : 4-dinitrophenylhydrazone in alkali was identical with that of pyruvic acid; and when cell division began, pyruvate disappeared from the medium. An alternative reaction sequence for pyruvate production from glycine would be by conversion to serine and deamination of the latter; however, extracts from cells grown with glycine contained no serine dehydrase.

We are indebted to the Agricultural Research Council for a studentship to one of us (for A. G. C.).

Formation of Glycerate from Oxalate by *Pseudomonas oxalaticus* (OXI) grown in Oxalate

AN organism growing on oxalate as sole source of carbon and of energy must possess biosynthetic pathways capable of transforming this compound into all its various cell constituents. It has been suggested[1] that it might do this by oxidizing the oxalate to carbon dioxide, followed by fixation of the latter in a similar manner to that of a chemosynthetic autotroph[2]. However, it has recently been found[3] that a key enzyme of the carbon dioxide fixation cycle of autotrophs, carboxydismutase, is not synthesized by *Ps. oxalaticus* during growth on oxalate; also, carbon dioxide is not appreciably incorporated into phosphorylated compounds by such cultures. These findings eliminate the operation of an autotrophic type of metabolism and suggest that biosynthesis of cell constituents from oxalate conforms with that occurring with C_2-compounds other than acetate (see first communication). The present communication presents results indicating that incorporation of oxalate follows a similar route to that suggested for other pseudomonad species growing on glycollate (first communication) or glycine (second communication). The essential difference lies in the reduction of oxalate to glyoxylate, the latter compound being the first common intermediary metabolite of these three growth substrates.

Growing cultures of *Ps. oxalaticus* were incubated with [^{14}C] oxalate and the course of entry of the isotopic carbon into the cells was followed by chromatographic and radioautographic techniques already described[4,5]. The large amount of residual radioactive oxalate, which obscured the area of the chromatogram in which many phosphorylated compounds are found, was removed by incubating the aqueous eluates of such areas with oxalate decarboxylase obtained from *Collybia velutipes*[6]. This enzyme specifically decarboxylates oxalate to formate and carbon dioxide, both of which were easily removed on further chromatography. The results of this analysis are shown in Fig. 1, the percentages of the total radioactivity on each chromatogram that were contained in the separated compounds being plotted as functions of time. The only labelled compounds formed in 3 sec. and isolated under these conditions were glycine and phosphoglycerate. During the incubation period of 3–10 sec., the percentage of radioactivity contained in glycine diminished, while that in phosphoglycerate increased. This shows that isotope from oxalate enters glycine first and then phosphoglycerate, other metabolites such as sugar phosphates and alanine become labelled later. The following work with cell-free extracts indicates the possible nature of these initial transformations.

Crude, cell-free extracts prepared from the organism catalyse a rapid anaerobic decarboxylation of glyoxylate in which one mole of carbon dioxide is formed from two of glyoxylate. Using [^{14}C] glyoxylate

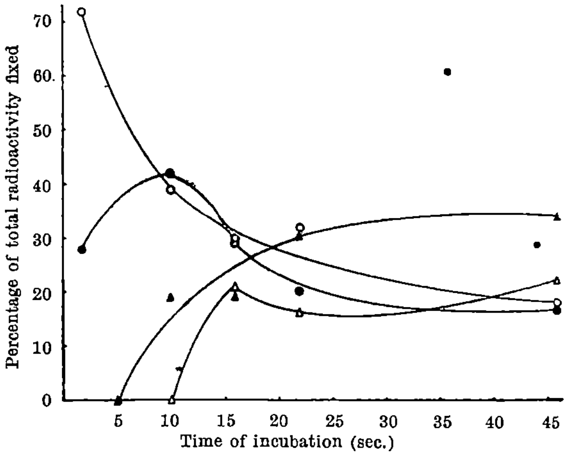

Fig. 1. Incorporation of [^{14}C] oxalate by *Ps. oxalaticus* grown in oxalate. Percentage of the total radioactivity present on each chromatogram that was contained in the separated compounds, plotted against time of incubation: ○—○, glycine; ●—●, phosphoglycerate; △—△, alanine; ▲—▲, sugar phosphates

(10^4 counts/min., under the conditions of radioassay used), and analysing the reaction products by chromatography and radioautography, the formation of radioactive glycerate (2,380 counts/min.) has been found after 15 min. anaerobic incubation, the yield of glycerate was increased almost three-fold by the addition of reduced diphosphopyridine nucleotide. No other radioactive product was found. These reactions are similar to those found in the pseudomonads grown in glycollate (first communication) and postulated in pseudomonads grown in glycine (second communication), and demonstrate a reductive conversion of glyoxylate to glycerate. The formation of some glycerate in the absence of added reduced diphosphopyridine nucleotide is probably due to endogenous reduced diphosphopyridine nucleotide present under the anaerobic conditions.

Formation of [^{14}C] glycerate (710 counts/min) was also observed in these extracts from [^{14}C] oxalate (2×10^4 counts/min.) in the presence of acetyl coenzyme A and reduced diphosphopyridine nucleotide. No other product was found on the chromatograms. Addition of these co-factors separately resulted in little synthesis of glycerate (less than 160 counts/min.).

These results indicate that the following reactions may occur in the crude extract, under the test conditions:

(i) $2 \text{ oxalate} + 2 \text{ acetyl CoA} \rightarrow 2 \text{ oxalyl CoA} + 2 \text{ acetate}$;

(ii) $2 \text{ oxalyl CoA} + 2 \text{ DPNH}_2 \rightarrow 2 \text{ glyoxylate} + 2 \text{ CoA} + 2 \text{ DPN}$;

(iii) $2 \text{ glyoxylate} + \text{DPNH}_2 \rightarrow \text{glycerate} + \text{CO}_2 + \text{DPN}$

Reaction (i), involving an acetyl coenzyme A transphorase, would lead to oxalyl coenzyme A, evidence for the existence of which has previously been presented[7].

The reduction of an acyl coenzyme A grouping to an aldehyde grouping, as suggested in reaction ii, has already been demonstrated[8] in extracts of *E. coli* with acetyl coenzyme A:

$$\text{acetyl CoA} + \text{DPNH}_2 \rightarrow \text{acetaldehyde} + \text{CoA} + \text{DPN}$$

The overall effect of the reactions would be reductively to condense oxalate to glycerate and carbon dioxide.

Under the conditions of chromatography used in the whole-cell experiments, the presence of glyoxylate, the first labelled compound to be made from the activated oxalate in reaction ii, would not be observed. However, transamination reactions leading to [^{14}C] glycine formation would reflect the presence of [^{14}C] glyoxylate. The behaviour of tartronic acid semialdehyde (the postulated intermediate (preceding communications) in reaction iii) under the conditions of chromatography are not known. The presence of a glyceric acid kinase, as in the glycollate-grown *Pseudomonas ovalis* Chester (see first communication), could lead to the early formation of radioactive phosphoglycerate from glycerate, the product of reaction iii. The appearance thereafter of isotope in sugar phosphates, alanine and C_4-compounds could then be expected from established metabolic pathways.

Full details of this work will be published elsewhere.

We thank Sir Hans Krebs for his interest and encouragement. CONSTITUENTS OF HUMAN HÆMOGLOBIN

Separation of the Peptide Chains of Human Globin

Schroeder and his colleagues[1] reported that human hæmoglobin is composed of four polypeptide chains of two different kinds, now referred to as α- and β-chains. Since human hæmoglobin has two identical half-molecules, each half-molecule contains one α- and one β-chain. It was of interest to separate these two different polypeptide chains and to find the distribution between them of tryptic peptides 4, 23 and 26 (ref. 2) which contain the changes in amino-acid sequence associated with the abnormal human hæmoglobins S (ref. 3) and C (ref. 4), D_α (ref. 5) and I (ref. 6), and D_β (ref. 5) and E (ref. 7), respectively (Table 3).

Itano and Singer have shown[8] that human hæmoglobin splits into two *unequal* half-molecules during dissociation at *p*H 4·3. Presumably, there are units in the hæmoglobin molecule which can be represented by αα and ββ. By an ingenious experiment using this type of reversible dissociation, Vinograd, Hutchinson and Schroeder[9] were able to show that in a mixture of hæmoglobins A and S, the αα half-molecule is interchangeable, whereas the ββ one is not. These authors argued that the β-chain in hæmoglobin S is therefore different and that it carries the mutational change associated with hæmoglobin S. Their findings are confirmed by the experiments to be presented in this article, in the course of which the α- and β-chains themselves were prepared and examined.

The splitting of horse hæmoglobin was well demonstrated by Reichmann and Colvin[10], who calculated from physical studies that the molecule is composed of four chains, of two different kinds. By prolonged boundary electrophoresis at very low *p*H, these different polypeptide chains were separated. Indications of the presence of four sub-units had previously been obtained by osmometry in strong salt solutions of both horse and human hæmoglobins[11]. In the present work, the initial experiments with human globin and hæmoglobin were modelled on Reichmann and Colvin's procedure. Whereas their method gave us results with horse globin which were similar to those published by these authors, all attempts failed to obtain indications of splitting of the human globin at low *p*H values. Further attempts were based on the experiences of Brand and Johnson[12], who were able to dissociate the seed protein legumin into about six similar sub-units by the action at alkaline *p*H of sodium dodecylsulphate.

The first positive indications that human hæmoglobin could be broken down to single chains came when human hæmoglobin A treated with sodium dodecylsulphate was examined in the ultracentrifuge at room temperature and *p*H 8·6. A single, symmetrical peak was seen, but the uncorrected sedimentation constant of $2 \cdot 0 \times 10^{-13}$ agreed reasonably well with a constant for sperm whale myoglobin (molecular weight 17,000) of $2 \cdot 3 \times 10^{-13}$ (uncorrected) obtained under identical conditions. These findings indicated that under these conditions such a hæmoglobin molecule was breaking down into quarter units, that is, into four polypeptide chains, the number expected from the analysis of the N-terminal amino-acids[1]. The corrected sedimentation constants (Table 1) are rather higher than might have been expected for quarter sub-units, no doubt due to the combination with rather large amounts of sodium dodecylsulphate. Boundary electrophoresis at 0·9° C. (Fig. 1) revealed two well-defined components in the ascending limb, although the boundaries on the descending side were not so well resolved. The final composition of this solution was: protein, 2·2 per cent; veronal, 0·12 *M*; sodium dodecylsulphate, 0·026 *M*; 0·36 gm. of sodium dodecylsulphate per gm. protein. This solution was dialysed in the cold against 43 volumes of 0·12 *M* veronal buffer, *p*H 8·6, overnight before electrophoresis.

Boundary electrophoresis in the Perkin–Elmer model 38*A* apparatus with continuous compensation produced milligram quantities of one of the two components as shown in Fig. 1. After some 24 hr. the 'fast' component or chain was removed from the cell and dialysed exhaustively against cold water before lyophilization.

Such a separation was quite reproducible, although there are reasons for believing that the exact proportion of sodium dodecylsulphate is critical. The method is also effective when hæmoglobin itself is used. Here, however, the two chains have slightly higher mobilities (see Table 1) due no doubt to the additional negative charges of the hæm groups.

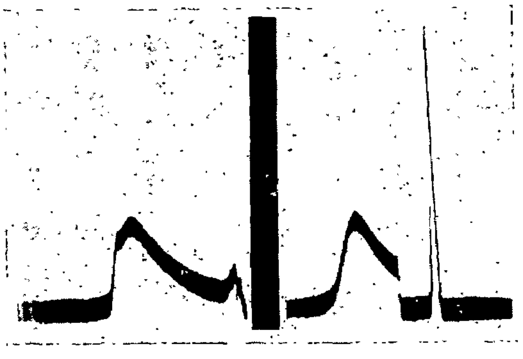

Fig. 1. Electrophoresis of human globin with sodium dodecylsulphate in veronal buffer, *p*H 8·6, ionic strength 0·12. Ascending limb on the right

Table 1. Behaviour of Globin and Hæmoglobin in the Presence of Sodium Dodecylsulphate

	Globin–sodium dodecylsulphate	Hæmoglobin–sodium dodecylsulphate
Electrophoretic mobilities		
'Fast' chain (β)	$10 \cdot 7 \times 10^{-5}$ cm.^{1} sec.$^{-1}$ V.$^{-1}$	$12 \cdot 7 \times 10^{-6}$ cm.^{2} sec.$^{-1}$ V.$^{-1}$
'Slow' chain (α)	$9 \cdot 6 \times 10^{-5}$ cm.^{3} sec.$^{-1}$ V.$^{-1}$	$11 \cdot 3 \times 10^{-5}$ cm.^{2} sec.$^{-1}$ V.$^{-1}$
Sedimentation constant (corrected S_{20})	$2 \cdot 40 \times 10^{-13}$	$2 \cdot 20 \times 10^{-13}$

Protein concentration = 2·2 per cent.

Samples of the 'fast' chain have been subjected to tryptic digestion by the methods previously described[2], although with the help of a Jacobsen-Leonis *p*H-stat[13]. Comparison of fingerprints from such digests with those of ordinary hæmoglobin digests and of digests of globin which had been treated with sodium dodecylsulphate and dialysed, showed that approximately half the usual tryptic peptides were absent. This was confirmed by the examination of tryptic peptides using one-dimensional paper electrophoresis at *p*H 6·4 (ref. 2) followed by development with ninhydrin and with reagents specific for the amino-acids histidine, tyrosine, arginine and tryptophan[14]. There was a little doubt about the presence or absence in the 'fast' chain of a few peptides, but it was clear that peptide 26 (hæmoglobin E and D_{β} changes) is present, whereas peptide 23 (hæmoglobin D_{α} and I changes) is absent and must be on the 'slow' chain. Peptide 4 (hæmoglobin S and C changes) is present, as was shown by electrophoresis at *p*H 3·6 of the band of neutral peptides obtained at *p*H 6·4, followed by a qualitative analysis of the amino-acid composition of the peptide containing histidine. Hence peptides 4 and 26 are on the 'fast' chain and peptide 23 is presumably on the 'slow' chain.

These findings confirm Schroeder's conclusion about the presence of two types of polypeptide chain in human hæmoglobin. Further experiments showed that the 'fast' chain is the β-chain, and not the α-chain as provisionally indicated[15].

In order to obtain a clearer picture of the distribution of the tryptic peptides between the α- and the β-chain, it was clearly desirable to prepare both chains and to identify them. Wilson and Smith[16] have worked out three ways of obtaining pure samples of the two different polypeptide chains of horse globin. They use preparative boundary electrophoresis at low *p*H, fractional precipitation with acid/acetone and ion exchange chromatography in a urea gradient. The last method was used, without modification, in the present experiments with globin from human hæmoglobin A. Whole globin was fractionated on an 'Amberlite IRC-50/XE 64' or 'CG 50' type 2 column with a urea gradient[16] of 2 *M*–8 *M*, always adjusted to *p*H 1·9 with hydrochloric acid. As Fig. 2 shows, two peaks are obtained, representing the α- and the β-chain, in that order, although the separation is poorer than that obtained by Wilson and Smith for horse globin. It was to be expected from their behaviour in boundary electrophoresis that the human globin chains would be more difficult to separate on an ion-exchange column. No doubt the method could be adapted to suit human globin better than it does at present. Wilson and Smith found three peaks in the case of horse globin, peaks 2 and 3 both having the same N-terminal dipeptide, namely, valyl-glutamyl-. The reason for the doubled peaks could be association of the molecules of this chain—shown by these chains in solution—or it could be connected with the fact that horse hæmoglobin usually shows two electrophoretic components. If the latter explanation be correct, then this electrophoretic difference can be assumed to reside in the polypeptide chain of horse globin which begins with valyl-glutamyl-. Since all carboxyl groups are uncharged at such a low *p*H, the difference would probably involve the basic amino-acids of this chain.

The chains were obtained by dialysis and freeze drying. In part they were digested with trypsin after heat denaturation. Examination of such digests by fingerprinting[2] and by one-dimensional ionophoresis at *p*H 6·4[2] showed that the known tryptic peptides are fairly evenly distributed between the two fractions (Fig. 3). The investigation of some of these peptides is still proceeding. By the methods used in the investigation of the human hæmoglobins 'D' (ref. 5)—particularly by specific staining reactions—it was possible to show that peptide 23 and peptide 26 occurred in the fractions I and II, respectively. This is interesting, because peptide 23 is involved in the mutations which result in hæmoglobins I and D_α and peptide 26 in hæmoglobins E and D_β. The location of peptide 4 (hæmoglobins S and C mutations) was not immediately apparent, because in hæmoglobin A this peptide is one of several uncharged peptides at the *p*H used for the ionophoresis, namely, 6·4. However, when the neutral peptides from digests of the two chains were compared by ionophoresis at *p*H 3·6, it became clear that peptide 4 is part of the chain in fraction II, namely, the β-chain (Fig. 3). This is in agreement with Vinograd and Schroeder's findings[9].

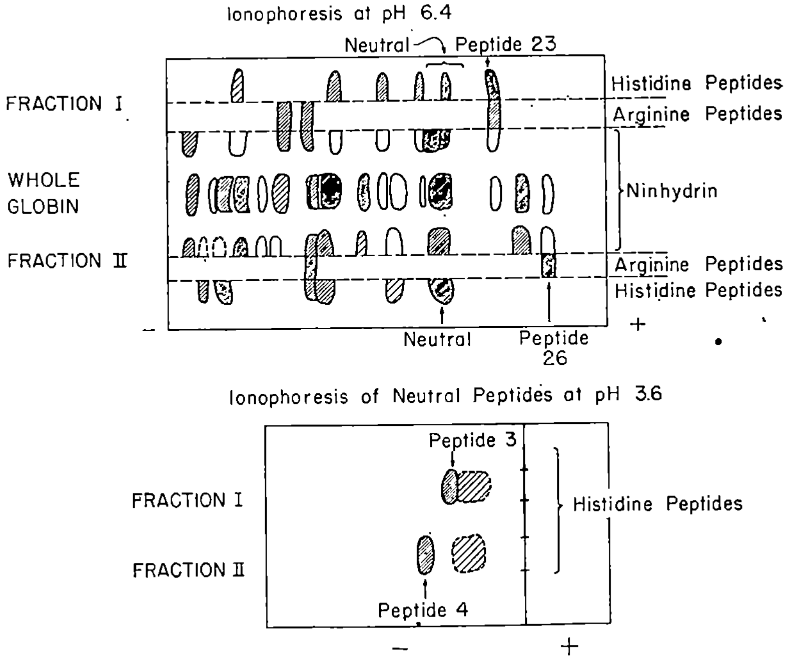

Fig. 3. Tracings of ionograms of tryptic digests; ionophoresis at *p*H 6·4. Colour reactions for specific amino-acids as in ref. 14

In order to identify fractions I and II with Schroeder's α- and β-chain, each fraction as well as whole globin were subjected to degradation from the amino-end with Fraenkel-Conrat's paper strip modification[17] of the Edman method. Table 2 shows that fraction I begins with valyl-leucine and is therefore the α-chain, whereas II begins with valyl-histidine- and is the β-chain. Table 3 indicates the distribution of the peptides carrying the various mutational alterations.

These results have interesting genetic implications[15]. The findings of the amino-acid changes in hæmoglobins S, C and E support the widely accepted hypothesis of a correlation between the linear fine-structure of the polypeptide chain controlled by that gene. When discussing a protein such as human hæmoglobin, which has two kinds of peptide chains, one is tempted to extend these ideas in the following way: suppose that there are two hæmoglobin genes; an 'α-chain gene' to control the amino-acid sequence of the α-peptide chain, and a 'β-chain gene'. Mutations may affect one or the other of these genes; for

	β-Peptide chain	
Hb-S, Hb-C		4
Hb-D_{β}, Hb-E		26

example, the hæmoglobin S, C, D_{β} and E mutations would, in this picture, be expected to occur on the β-chain gene, whereas, for example, the hæmoglobin D_{α} and I changes would occur as the result of alteration on the α-chain gene. Moreover, the loci of the two mutations of the α-chain gene would be expected to be very close together, since they effect changes within the same small peptide. The loci of the four β-chain mutations would in this formulation be found in two pairs—hæmoglobins D_{β} and E close together and hæmoglobins S and C in the identical location[4].

The possibility that there might be two hæmoglobin genes was put forward by Neel and his colleagues[18] in order to explain the pattern of inheritance of both hæmoglobin S and hæmoglobin G in one family. It has also been proposed by Smith and Torbert in connexion with a family tree involving hæmoglobin 'Hopkins 2' (ref. 19). The present results, the assignment of chemical alterations to one or other of the two peptide chains, enable us to present a more detailed and more convincing picture of the gene-protein relationship in the hæmoglobins.

I wish to thank Dr. D. B. Smith and Dr. J. Vinograd for their courtesy in allowing me to see copies of their papers prior to publication. Thanks are also due to Dr. P. Johnson, of Cambridge, for many helpful discussions. The expert assistance of Mrs. R. Fishpool and Miss E. Sullivan is gratefully acknowledged, as is the help given by Mr. Boon, of the Biochemical Laboratory, Cambridge, who carried out the ultracentrifuge determinations. This work was supported in part by a grant from the Medical Foundation, Inc., Boston, the help of which is gratefully acknowledged.

Comparison of Normal Adult Human Hæmoglobin with Hæmoglobin I by 'Fingerprinting'

ACCORDING to Rucknagel *et al.*[1] the occurrence of hæmoglobin I is genetically determined but does not appear to cause a severe anæmia. It has a lower isoelectric point than the normal hæmoglobin (hæmoglobin-A) in a moving-boundary electrophoresis experiment, and migrates more rapidly in alkaline buffers and less rapidly in acid buffers ; the electrophoretic mobility differences[2] between hæmoglobins A and I are 0·6 to 0·7 × 10^{-5} cm^2. $sec.^{-1}V.^{-1}$. We wish to report that in hæmoglobin I a mutational alteration is found in tryptic peptide 23 (ref. 3), the peptide which also contains the change[4] associated with hæmoglobin D_{α}. The other peptides appear to be normal. In hæmoglobins S and C, tryptic peptide 4 is altered[5,6] and tryptic peptide 26 in hæmoglobins E (ref. 7), and D_{β} (ref. 4). Therefore, we know of at least three parts of the molecule which undergo changes due to mutation in the gene or genes which control the biosynthesis of the hæmoglobin molecule.

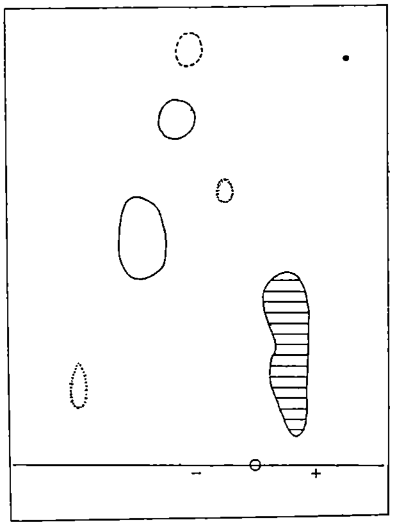

Fig. 1. Tracing of 'fingerprint' (ref. 3) of the tryptic digest from hæmoglobn I developed for tryptophan-containing peptides (ref. 10). The area of peptide 23 is cross-hatched, indicating a positive reaction for tryptophan, whereas peptide 23 of hæmoglobin A is negative. Electrophoresis was carried out at *p*H 6·4 in the horizontal direction and subsequent chromatography in butanol/acetic acid in the vertical direction (ref. 3)

The blood specimen was made available by Dr. Tocantins from a patient (J. W.) with hæmoglobin A-I and whose red cells sickled under certain conditions[8]. Hæmoglobin I was separated by means of the starch block electrophoresis technique of Kunkel[9]. 'Purified' hæmoglobin I was denatured by heat and digested with trypsin[3], and from it was obtained a mixture of peptides for examination by 'fingerprinting'.

Such a 'fingerprint' revealed that peptide 23 of this hæmoglobin moved more rapidly towards the anode than the normal peptide, in line with peptides 24 and 25. A specific colour reaction[10] (Ehrlich's reagent) on a 'fingerprint' revealed that peptide 23 of hæmoglobin I contains tryptophan whereas the corresponding one in hæmoglobin A does not (Fig. 1). In a one-dimensional paper electrophoresis it is possible to demonstrate the new tryptophan-containing peptide under an ultra-violet lamp. It is not yet clear whether other amino-acids in peptide 23 are involved in the change. The specific colour reactions[10] carried out directly on the ionogram revealed the presence of arginine, tyrosine, and histidine (Fig. 2) which also occur in peptide 23 of normal hæmoglobin. It is hoped that further experiments will reveal in detail the change undergone by peptide 23.

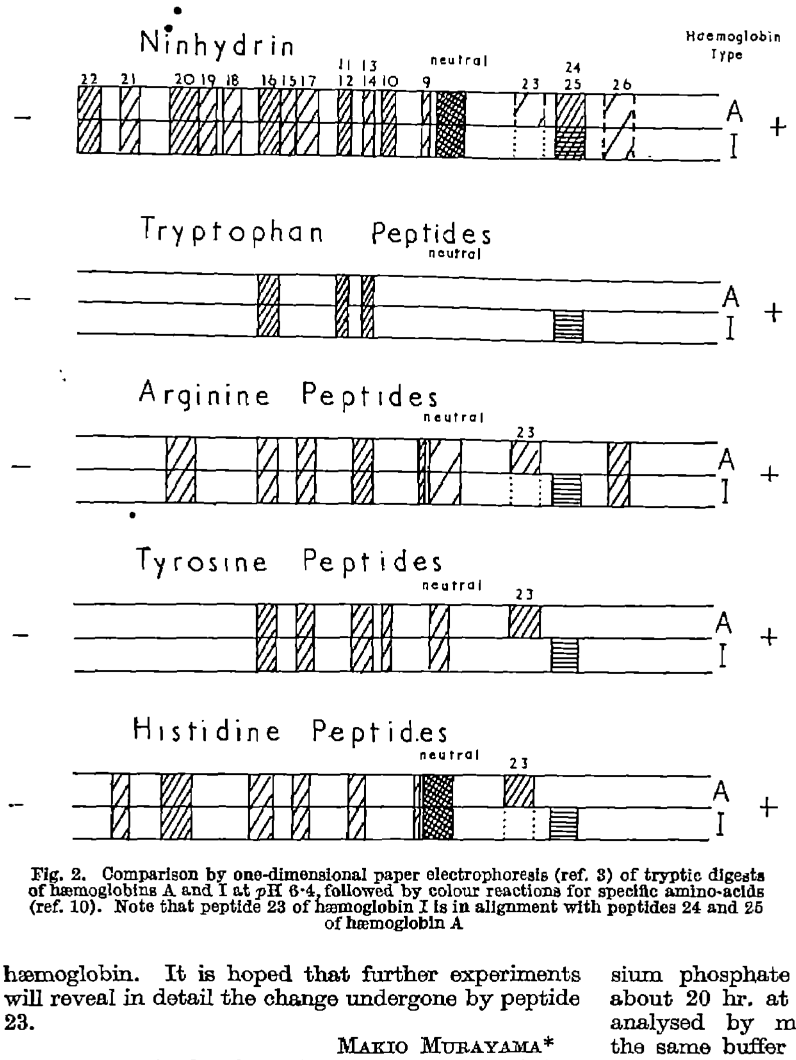

Fig. 2. Comparison by one-dimensional paper electrophoresis (ref. 3) of tryptic digests of hæmoglobins A and I at pH 6·4, followed by colour reactions for specific amino-acids (ref. 10). Note that peptide 23 of hæmoglobin I is in alignment with peptides 24 and 25 of hæmoglobin A

Formation of Normal and Doubly Abnormal Hæmoglobins by Recombination of Hæmoglobin I with S and C

A MOLECULE of normal human adult hæmoglobin (hæmoglobin A) is symmetrical about a dyad axis[1] and is composed of four hæm groups and four polypeptide chains, a pair of α-chains and a pair of β-chains[2]. Hæmoglobins A, S, and C dissociate asymmetrically in acid into two unlike sub-units, each of which consists of a pair of identical chains and two hæms[3,4]. Complete molecules are regenerated from these sub-units when an acidified solution is neutralized, and sub-units are exchanged when a mixture of a pair of unlike hæmoglobins is dissociated and recombined. The chemical abnormalities of hæmoglobins S and C occur at the same place in the β-chain[5,6]. Hæmoglobin I, on the other hand, is abnormal in the α-chain[7]. We wish to report evidence for the formation of hæmoglobin A and a doubly abnormal molecule when hæmoglobin I is recombined with hæmoglobin S or C.

A mixture of hæmoglobins A and I received from Dr. L. M. Tocantins was used[8]. The mixture, and mixtures of it with hæmoglobin S and with hæmoglobin C, were examined electrophoretically both before and after recombination. All samples were in the form of carbonmonoxyhæmoglobin. Recombined mixtures were prepared by dissociation in acetate-sodium chloride buffer of pH 4·7, Γ/2 0·2 (ref. 4) for 4 hr. at 5° C. followed by dialysis against potassium phosphate buffer of pH 6·3, Γ/2 0·02, for about 20 hr. at 5° C. The resulting samples were analysed by moving-boundary electrophoresis in the same buffer for 5 hr. at 3° C. with a potential gradient of 8·5 V. cm.$^{-1}$. Control electrophoretic analyses on undissociated aliquots of the same mixtures were carried out under identical conditions. Satisfactory resolution was obtained only in the ascending limb. When a mixture of carbonmonoxyhæmoglobins A, I and S was recombined, a new component appeared between A and I. At the same time the proportion of hæmoglobin A increased and the proportions of I and S decreased. Recombination of carbonmonoxyhæmoglobins A, I and C produced no new electrophoretic component; however, the proportion of hæmoglobin A increased with decrease of I and C. No new component or change in proportions occurred when carbonmonoxyhæmoglobins A and I were recombined. The results are shown in Fig. 1 and Table 1. The numerical values of Table 1 are directly proportional to the areas under the peaks of Fig. 1. These areas are probably anomalous because of low ionic strength of buffer. However, since aliquots of the same mixture were used in each pair of analyses, change in relative areas following recombination must reflect change in true composition.

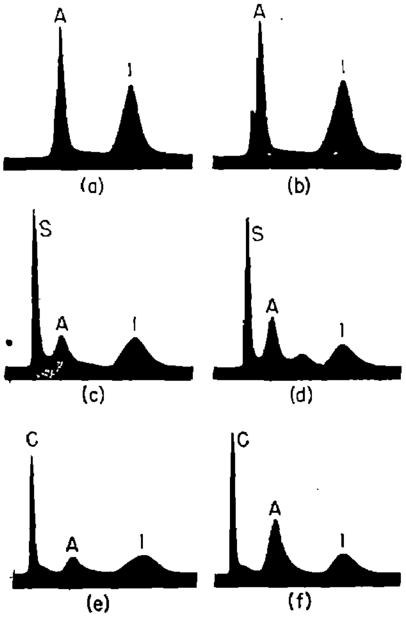

Fig. 1. Ascending boundary patterns from electrophoresis of 1·0 per cent carbonmonoxyhæmoglobin in phosphate buffer of *p*H 6·3, Γ/2 = 0·02. The direction of migration is from right to left. From left to right the components are: (*a*) A, I control; (*b*) A, I recombined; (*c*) S, A, I control; (*d*) S, A, I recombined. Note the new component ($s_2i_2^{-2}$) between A and I and the increase in proportion of A; (*e*) C, A, I control; (*f*) C, A, I recombined. Note the increase in the proportion of A ($a_2u_2 + c_2i_2$)

A simplified nomenclature[3,4] is convenient for discussion of dissociation-recombination phenomena. The β-chains of hæmoglobins A, S and C are *a*, *s* and *c*, respectively; and their common α-chain is *u*. The abnormal α-chain of hæmoglobin I is *i*, and its β-chain, presumably normal, is *a*. The abnormalities in net charge of hæmoglobins S and C are + 2 and + 4, respectively[5]. The mobility of hæmoglobin I indicates an abnormality in net charge of close to − 4. The net charge of the unaltered portions of the molecules may be omitted in the present discussion; accordingly carbonmonoxyhæmoglobins A, S, C and I may be written a_2u_2, $s_2u_2^{+2}$, $c_2u_2^{+4}$, and $a_2i_2^{-4}$, respectively. Asymmetric dissociation would result in the sub-units a_2, s_2^{+2}, c_2^{+4}, u_2, and i_2^{-4}.

We can now interpret our results with the assumption of asymmetrical dissociation and recombination. When a mixture of a_2u_2 and $a_2i_2^{-4}$ is recombined, exchange of a_2 sub-units can occur without effect on electrophoretic composition, in agreement with our observations on the mixture of carbonmonoxyhæmoglobins A and I. The situation is analogous to the exchange of u_2 sub-units when mixtures of carbonmonoxyhæmoglobins A, S and C were recombined. Recombined mixtures yielded the same electrophoretic patterns as corresponding untreated mixtures, and exchange was demonstrated by use of labelled molecules[3,4]. Since recombination of carbonmonoxyhæmoglobin A with S, C or I is not associated with change in composition, it appears that the effects observed in the mixture A, S and I, and in the mixture A, C and I, arise from recombination of S and C, respectively, with I. Asymmetrical recombination of $s_2u_2^{+2}$ and $a_2i_2^{-4}$ would result in a mixture of a_2u_2, $s_2i_2^{-2}$, and the original components. The net effect on the composition of a mixture of carbonmonoxyhæmoglobins A, S and I would be the appearance of a new component between A and I, increase in A and decrease in S and I. Asymmetrical recombination of $c_2u_2^{+4}$ and $a_2i_2^{-4}$ would produce a mixture of a_2u_2, c_2i_2, and the original components. Since c_2i_2 has the same net charge as a_2u_2, no new component would be detected. The effect on a mixture of carbonmonoxyhæmoglobins A, C and I would be an increase in the A component, which includes both a_2u_2 and c_2i_2, and decrease in C and I.

Table 1. COMPOSITION OF HÆMOGLOBIN MIXTURES BEFORE AND AFTER RECOMBINATION

Mixture		Electrophoretic composition: per cent of total $a_2i_2^{-4}$ (I)	$s_2i_2^{-2}$	a_2u_2 (A)	$s_2u_2^{+2}$ (S)	$c_2u_2^{+4}$ (C)
A+I	Control	53	—	47*	—	—
	Recombined	55	—	45*	—	—
A+I+S	Control	34	—	24*	42	—
	Recombined	23	11	32	34	—
A+I+C	Control†	36	—	20	—	44*
	Recombined	22	—	42‡	—	36*

* Includes 3–4 per cent of trailing shoulder.

† Re-run of original control; C peak too sharp in original for determination of area.

‡ Probably includes c_2i_2.

Thus our observations are consistent with the assumption of asymmetrical recombination between carbonmonoxyhæmoglobin I, which is abnormal in the α-chain, and carbomonoxyhæmoglobin S or C, which is abnormal in the β-chain, to produce carbonmonoxyhæmoglobin A and a carbonmonoxyhæmoglobin molecule composed of two different pairs of abnormal chains. According to these results, it is possible for an individual who is heterozygous for an abnormality in each chain to have four molecular species of adult hæmoglobin in his red cells, provided the two types of chains are physically independent up to the time they associate to form complete molecules. If the abnormalities in net charge of the two abnormal chains are equal and opposite, the four species would appear as three electrophoretic components. In either circumstance one of the four species would be composed entirely of normal chains. Formation of a normal protein molecule by association of the normal components of two different abnormal molecules suggests one possible mechanism for extranuclear formation of a normal enzyme molecule by the co-operative action of two mutant strains of the same organism, neither of which produces active enzyme[4].

Spectrum and Structure of the Free Methylene Radical

SEVENTEEN years ago, one of us[1] suggested that the so-called λ4050 group observed in comets was due to the free methylene radical (CH_2). This suggestion was not confirmed by later experiments[2-4]. Ever since the original misidentification of the 4050 group, experiments have been proceeding in this laboratory with the aim of finding the true spectrum of CH_2. However, it was only at the end of last year that some promising features were observed near 1400 A. in the flash photolysis of diazomethane. Recently, one of these features has been positively identified as due to free CH_2.

In the first order of our 3-m. vacuum spectrograph the group of features under consideration consists of six slightly diffuse 'lines' which show, on substitution with deuterium, a marked shift, thus establishing that the carrier of this group must contain one or more hydrogen atoms. The strongest feature in this group occurs in the flash photolysis of ordinary diazomethane at 1414·5 A., in fully deuterated diazomethane at 1415·8 A. When partly deuterated diazomethane is used, a third feature is observed at 1415·5 A. In this way it is shown that there are two hydrogen atoms present in the molecule responsible for this spectrum. While this made it very likely that CH_2, CHD and CD_2 are responsible for the observed spectra, conclusive proof could only be obtained by a study of the rotational fine structure of some of the features observed.

Unfortunately, it turned out that in the fourth order of our vacuum spectrograph all the features observed in the flash photolysis of ordinary diazomethane were rather diffuse. However, in observing the corresponding spectrum in deuterated diazomethane, it was found that the principal feature at 1416 A. did show a rather well-resolved fine structure. This difference between the deuterated and non-deuterated molecule is very similar to the condition found[5] for the 2160 A. band of CH_3 and CD_3, and is apparently due to the fact that a deuterated molecule predissociates much less easily than a non-deuterated molecule.

The fine structure of the 1415·8 A. feature in the deuterated molecule consists of a simple *P*- and *R*-branch, each of which shows a clear alternation of intensity. The presence of this alternation proves beyond doubt that there must be two symmetrically placed identical atoms (deuterium atoms) in the molecule. The absence of a *Q*-branch proves that this is either a parallel band of a linear molecule or the $K = 0$ sub-band of a parallel band of a (nearly) symmetrical top molecule such that rotation about an axis perpendicular to the figure axis exchanges the deuterium atoms. Further confirmation was obtained by the observation of a similar band without an alternation of intensity in the flash photolysis of partly deuterated diazomethane. The spacing of the lines in the fine structure of the bands in the fully deuterated and partly deuterated compounds supplies values for the rotational constants (reciprocal moments of inertia) in the upper and lower states of the two molecules involved. These values are:

$$B'(CD_2) = 3{\cdot}59_5 \qquad B''(CD_2) = 3{\cdot}95_0 \text{ cm.}^{-1}$$
$$B'(CHD) = 4{\cdot}80_8 \qquad B''(CHD) = 5{\cdot}33_3 \text{ cm.}^{-1}$$

The magnitudes of these rotational constants are compatible only with the assumption that the molecule involved is of the type XD_2 and XHD respectively. From the method of production of the spectrum it appears impossible that X can be anything but C (carbon). The ground-state and first excited state of NH_2 are known, and definitely are not involved in the bands under investigation. Moreover, both the well-known spectra of ND_2 and ND in the visible and in the ultra-violet regions are absent, while the spectrum of CD (and CH) is very prominent. Thus we consider the identification of the carrier of the spectrum as free methylene as established.

The simplest and most obvious interpretation of the observed fine structure would appear to be that the molecule is linear in both the upper and lower states of the transition. With this assumption one obtains two independent values for the CH (or CD) distance from the rotational constants of B'' of CD_2 and CHD, namely:

$$r_0'' = 1{\cdot}029 \text{ and } 1{\cdot}034 \text{ A.}$$

The slight difference could be accounted for by the effects of zero-point vibration.

If, on the other hand, one assumes the molecule to be non-linear and uses the two moments of inertia to determine the two structural parameters r_0'' and ∠HCH one finds:

$$r_0'' = 1{\cdot}071 \text{ A. and } \angle HCH = 140^\circ.$$

However, these results imply that the rotational constant $A''(CD_2)$ would be 41·7 cm.$^{-1}$ and therefore several other sub-bands with $K = 1, 2, 3, \ldots$ would be expected, for which no evidence has been found. The absence of these sub-bands could be accounted for if it is assumed that the upper state is linear or that levels with $K \neq 0$ in the upper state are strongly predissociated and therefore escape observation. On account of the effect of zero-point vibration, a definite decision between the linear and non-linear structure of the molecule in the ground-state is not yet possible. All one can say definitely at this moment is that the HCH angle is between 140° and 180°.

The fact that in CD_2 the strong lines are those of odd J indicates that the lower electronic state of the transition is not totally symmetrical. Indeed, for linear CH_2 the predicted[6] ground-state is readily seen to be $^3\Sigma_g^-$, which would lead exactly to the observed intensity alternation. It is conceivable that the lower state of the transition, even though it has been observed in absorption, is not the ground-state of the molecule, but this would entail the assumption that the molecule can survive up to 5,000 collisions with the inert gas molecules present before going over to the real ground-state.

While the question of the ground-state still remains to be settled, we believe that it has been definitely established that the spectrum under consideration is due to the free methylene radical and that in the lower state of the observed transition the molecule has an HCH angle between 140° and 180° and a non-totally symmetrical electronic structure. The life-time of the CH_2 radical under the conditions of our experiment (partial pressure of diazomethane before photolysis 0·02 mm., partial pressure of inert gas 2 mm. or more) was about 15 μsec., that is, of the order of the time between collisions of CH_2 with CH_2N_2.

Many members of this laboratory have contributed to the final success of these investigations by their suggestions, critical advice and other help. To all of them we are greatly indebted.

Removal of Dipolar Broadening of Nuclear Magnetic Resonance Spectra of Solids by Specimen Rotation

THE nuclear magnetic resonance spectrum of a solid rotated at high speed consists of a narrowed central line and a set of side-spectra spaced at integral multiples of the rotation rate of either side[1,2]. The interaction energy between each pair on nuclear magnets in the solid contains the angular factor $(3 \cos^2 \theta - 1)$, where θ is the angle between the internuclear vector and the applied field. When the solid rotates about an axis making an angle α with the applied field, the angular factor may be expressed[3] as the sum of its mean value $\frac{1}{2} (3 \cos^2 \alpha - 1) (3 \cos^2 \gamma - 1)$, where γ is the angle between the internuclear vector and the axis of rotation, and two time-dependent terms, $(3/2) \sin 2\alpha \sin 2\gamma \cos \omega_r t$ and $(3/2) \sin^2 \alpha \sin^2 \gamma \cos 2 \omega_r t$, where ω_r is the angular frequency of rotation. The two time-dependent terms lead to the formation of the side-spectra. It should be noted that when α is 90°, as in our earlier experiments[1,2], the first of these terms is absent, so that side-spectra occur in this case at even multiples of ω_r only; for general α, the side-spectra occur at odd and even multiples of ω_r. The form of the mean value of the angular factor for each nuclear pair leads to the conclusion that the central spectrum should have the shape found for the static crystal when the applied field is directed along the axis of rotation, but reduced in width by the factor $\frac{1}{2} (3 \cos^2 \alpha - 1)$, and having a second moment[4] reduced by a factor $\frac{1}{4} (3 \cos^2 \alpha - 1)^2$. Thus, in particular, when α has the value $\cos^{-1} (1/\sqrt{3}) = 54° 44'$, the dipolar broadening of the central line should be removed[5]. With a speed of rotation large compared with the static line-width, the side-spectra will be displaced far from the centre and will be weak, leaving only a sharp central line broadened by residual non-dipolar causes.

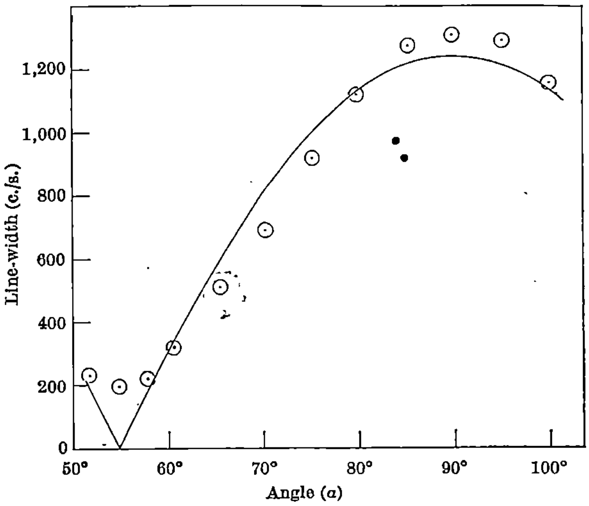

Fig. 1. Variation of line-width of the sodium-23 resonance spectrum of a rotating crystal of sodium chloride with the angle α between the axis of rotation and the direction of the applied field. The full line is the theoretical curve for a spectrum broadened solely by dipolar interactions; the circles are the experimental observations

We have extended our experiments on a rotating crystal of sodium chloride to cover a range of angles α from 50° to 100°. The axis of rotation was [001]. The measured width of the central line of the sodium-23 resonance spectrum determined between derivative maximum and minimum is plotted in Fig. 1. Also shown in Fig. 1 is the curve of $\frac{1}{2}|3 \cos^2 \alpha - 1|\delta\nu_0$, where $\delta\nu_0$ is the line-width for the static crystal with the applied field along [001]. The general agreement is quite good, but it is to be noticed that when $\alpha = 54° 44'$, the central line has a finite width of 200 c./s., which is greater than the instrumental breadth. This residual width may in this crystal arise from interactions between the electric quadrupole moments of the sodium-23 nuclei and electric field gradients caused by imperfections in the cubic crystal. The central line thus has a residual width about one-tenth of that for the static crystal, and a second moment of the order of 1 per cent of that for the static crystal. Such broadening would be difficult to detect while it is overlaid by the much larger dipolar broadening of the static crystal.

In Fig. 2 is shown the derivative spectrum for $\alpha = 54° 44'$ at a rotation rate of 810 c./s. The first three side-spectra are visible on either side. Although the rate of rotation was sufficient to separate the side spectra from each other and from the central line, it was insufficient to remove them from the scene.

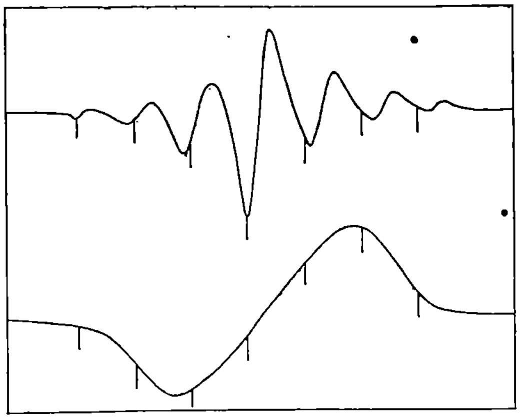

Fig. 2. The upper curve is the derivative spectrum for the crystal rotated at 810 c./s. about an axis making an angle 54° 44′ with the direction of the field. The lower curve is the derivative spectrum for the static crystal. The markers are 790 c./s. apart

Fig. 2 also shows, for comparison, a spectrum obtained when the crystal was at rest.

Several practical consequences appear to follow from the removal of dipolar broadening from the central line. In the first place, the position of the central resonance frequency can be determined with much greater precision; in our example the improvement is by a factor of ten. In this way a greater accuracy may be obtained in the measurement of nuclear magnetic moments when solid specimens are used. Secondly, the relative chemical shifts (and for metals, Knight shifts) may be determined with much greater precision. Thirdly, broadening or fine-structure caused, for example, by quadrupolar interactions, electron-coupled spin exchange or different chemical shifts on non-equivalent sites, may be revealed by the removal of the dipolar broadening which, in solids, usually masks them.

Electron Microscopy of Oleophobic Monolayers

Oleophobic monolayers of stearic acid on mica have been studied by means of the electron microscope. Mica was chosen as the substrate because clean surfaces, which are molecularly flat over large areas, are easily obtained by cleavage. Stearic acid was retracted from a solution in hexadecane in the manner described by Bigelow, Pickett and Zisman[1] and a preshadowed carbon replica of the surface taken; 40 per cent gold/palladium was found to be the most suitable shadowing material.

Fig. 1 shows a typical result. The contrast of the micrograph is enhanced by agglomeration of the shadowing material on those parts of the surface covered by stearic acid. It will be seen that the monolayer is present in islands, which measurement of shadow-lengths show to be 25 A. thick. A close examination of the monolayer islands does in some instances show a tendency for the metal particles to arrange themselves in lines, which may suggest some regular array, within the islands, of the micelles which Epstein[2] suggests exist in monolayers.

Monolayers of stearic acid retracted from the melt[3] do not show the island structure of those retracted from hexadecane solution, so this structure cannot be attributed to evaporation of stearic acid during pumping prior to shadowing, or to bombardment of the surface by metal particles. It is evident from Fig. 1 that the surface is only partially covered by stearic acid, so it is pertinent to ask how it is that the surface is oleophobic. It is suggested that hexadecane is incorporated in the monolayer. The attractive forces between hydrocarbon chains are believed to be responsible for the orientation of long-chain polar compounds at both the solid and liquid interfaces; and Sobotka and Rosenberg[4] have shown that it is possible to spread mixed films of stearic acid and long, straight-chain hydrocarbons on water surfaces, where the hydrocarbon will not spread by itself. A similar mechanism may operate in this case. Hexadecane is able to orient itself alongside adsorbed molecules of stearic acid, and may be gradually replaced as more stearic acid diffuses to the surface.

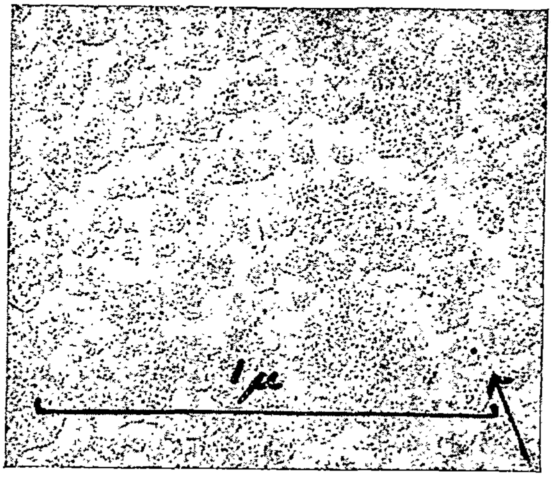

Fig. 1. Electron micrograph of a replica of a mica surface which has been dipped in a 0·1 per cent by weight solution of stearic acid in hexadecane for 30 sec. The arrow shows the direction of shadowing. The island structure of the monolayer is apparent

Although no quantitative results are available yet, it is evident from micrographs that the area covered increases with time of immersion, and with concentration of solution for a given time of immersion. Furthermore, if a monolayer is prepared by retraction of a drop on the mica surface, it is found that only a third of the surface is covered by acid. Fig. 2 shows a close-packed hexagonal arrangement of molecules where the black circles represent stearic acid and the white circles hexadecane. It can be seen that each hexadecane molecule has three stearic acid molecules among its six nearest neighbours. It is suggested that when a stearic acid molecule is adsorbed, hexadecane molecules are able to orient themselves beside it. When the condition in Fig. 2 is reached, the bulk liquid rests on an oleophobic surface of methyl groups and retracts, being unable to differentiate between the end groups of the acid and the hydrocarbon. Since the hexadecane has a much greater vapour pressure than stearic acid, it is pumped off during the preparation of the replica, and then the acid molecules collapse into islands as shown in Fig. 1. In no case has an oleophobic film been found to cover significantly less than a third of the surface.

The observations of Bigelow and Brockway[5], who find only a small reduction in contact angle when the

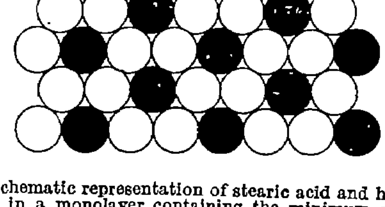

Fig. 2. Schematic representation of stearic acid and hexadecane molecules in a monolayer containing the minimum number of stearic acid molecules necessary for the surface to be oleophobic. The black circles represent stearic acid and the white hexadecane

density of adsorbed acid molecules is reduced by dipping in hexadecane, may be explained as a result of the reverse process taking place, hexadecane replacing stearic acid which has been dissolved away. These authors do point out that a surface may become oleophobic before the adsorption process is complete.

Identical observations have been made on retracted monolayers of long-chain aliphatic alcohols and primary amines. It has not been possible to observe any island structure when the mica has not been immersed in solution long enough for it to become oleophobic, although Bigelow and Brockway were able to obtain faint layer lines in electron diffraction pictures[5]. It may well be that any clusters of molecules oriented on the surface are too small to be replicated satisfactorily.

I am indebted to Dr. F. P. Bowden and Dr. D. Tabor of this Laboratory for helpful discussion, and to Joseph Lucas, Ltd., for a research grant.

Magnetometric Titration: a New Method of Chemical Analysis

It is well known that the addition of paramagnetic solutes to water brings about a marked reduction in the nuclear spin-lattice relaxation time of solvent protons[1], the inverse of the relaxation time being linearly related to solute concentration according to the equation:

$$(T_1^{-1} - T_0^{-1}) = \alpha \mu_N^2 C$$

where T_1 and T_0 are spin-lattice relaxation times in the presence and absence of added solute, respectively; α is a proportionality constant; μ_N is a parameter expressing the effectiveness of a particular solute in this phenomenon, sometimes called the 'effective' paramagnetic moment of the solute; C is the concentration of the solute. In the case of solutions of paramagnetic complex ions, the magnitude of the effect (that is, the value of μ_N) depends on the nature of the co-ordinated groups[2]. We find that the phenomenon enables the replacement of one ligand by another in solution to be followed with sufficient precision to form the basis for a method of determining the concentration of metal ions, and it is now suggested that this method of analysis should be widely applicable in cases where the addition of a complexing agent to the solution of a paramagnetic ion in solution causes the formation of a new complex ion of different μ_N and of high stability in solution. The analyses can conveniently be carried out by use of a low-resolution nuclear magnetic-resonance spectrometer.

The application of the method to the titration of nickel(II) is illustrated in Fig. 1. The breaks in the curve correspond to equivalence points, in a manner somewhat reminiscent of conductimetric titrations. Nickel(II) represents a particularly favourable and interesting case for this method, since the diamagnetic species $[Ni(CN)_4]^{2-}$ does not catalyse the spin-lattice relaxation at all. Values of $(T_1^{-1} - T_0^{-1})$, corrected for the dilution effect which accompanies addition of titrating agent, are plotted against the amount of potassium cyanide added to an ammoniacal solution of nickel cyanide, that is, a solution of $[Ni(NH_3)_6]^{2+}$ $[Ni(CN)_4]^{2-}$.

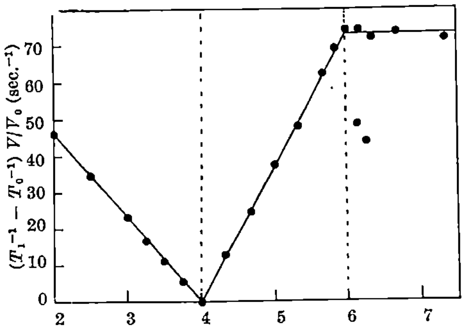

Fig. 1

The curve is interesting in that two equivalence points are observed. These occur after addition of four and six moles of cyanide per mole of nickel(II) respectively, and demonstrate the formation of stable species $Ni(CN)_4^{2-}$ and $Ni(CN)_6^{4-}$. Since present indications from other experimental methods are that $[Ni(CN)_6]^{4-}$ (in aqueous solution) is not paramagnetic, this particular result raises other problems, because only paramagnetic solutes are thought to be effective in catalysing spin-lattice relaxation.

A feature which makes the technique attractive in analytical chemistry is the small amount of solute required. In our apparatus sample volumes of 0·23 c.c. and concentrations of nickel(II) in the range 0·01–0·1 *M* were convenient, but both these values could be substantially reduced. The dilution during titration can be kept low by using a concentrated solution of titrating agent, but is easily allowed for by multiplying the values of $(T_1^{-1} - T_0^{-1})$ by V/V_0, where V_0 is the initial volume of the solution and V the volume after addition of titrating agent.

Other applications of the titration technique, for example, to the study of relative stability constants of different complexes in solution, readily suggest themselves.

It is hoped to publish more detailed accounts of the technique and experimental results elsewhere.

A Dose Test for Irradiated Polyethylene

Although a large body of results has been published on the changes of physical properties induced in ethylene polymers by irradiation, no description of an actual dose test has come to our notice. It happens during electron irradiation of objects that such factors as thickness may influence the dose received at any point so that it is desirable to have available a test which can be used to assess

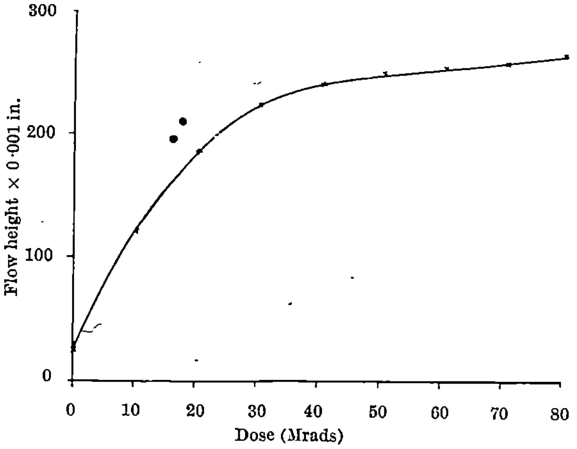

Fig. 1

the radiation dose received by a small amount of material.

In the case of polyethylene, Charlesby and Hancock[1] studied the effect of radiation dose on the relationship between elastic modulus and temperature. From this work a dose-evaluation test could easily be developed, but rather large test samples are required. Other work, which was the starting point for the present study, is due to Ballentine *et al.*[2] and to Lanza[3], who have shown that polyethylene acquires a progressive resistance to deformation with increasing radiation dose, and that the effect shows better at higher test temperatures. Their work does not go far enough for an accurate dose test to be derived from their results.

We have studied the deformation of irradiated polyethylene test pieces using a Williams plastimeter. Under a loading of 5 kgm. on a standard test piece at 150° C. the deformation in 3 min. varies with dose received up to 80 Mrad (Fig. 1). These particular data refer to 'Alkathene 2' (Imperial Chemical Industries, Ltd.) but similar results are obtained with other polyethylenes. The test can only be applied to samples from which cylindrical test pieces may be machined, or to sheets from which disks may be punched to make such a test piece; moulded test pieces at 150° C. revert to their original shape before moulding, so giving irregular cylinders. This effect is due to the well-known 'elastic memory'.

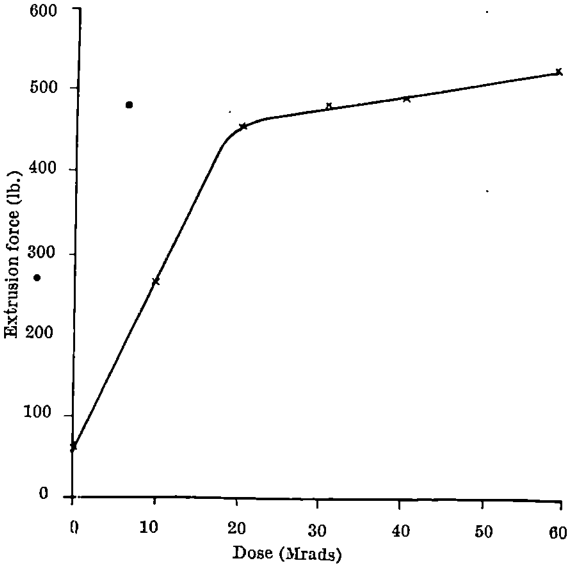

Fig. 2

To overcome this limitation another test has been developed in which the polyethylene is extruded at 150° C. using a Hounsfield tensometer with extrusion attachment. After a few moments the extrusion pressure settles down to a steady value which depends upon the dose received by the polyethylene (Fig. 2). These results refer to 'Alkathene 2' and also to highly expanded cellular polyethylene, which cannot be tested by the Williams plastimeter method.

The methods given appear to be suitable for testing all types of polyethylene for dose received where weights of only a few grams are available.

We are grateful to Mr. W. E. Simpson for helpful discussion and to Mr. T. R. Scott, director of research, for permission to publish this communication.

Secondary Ionization in Humid Air

Recent measurements of Townsend ionization coefficients by Prasad and Craggs[1] in these laboratories have revealed large variations in the values obtained for the secondary ionization coefficient γ in discharge gaps in air containing water vapour. For example, in humid air at a total pressure of 150 mm. mercury with a partial pressure of 15 mm. mercury of water vapour, its value for a 'Dural' cathode is $7 \cdot 5 \times 10^{-8}$ at $E/p = 45$ V./cm./mm. mercury as compared with a value of $2 \cdot 3 \times 10^{-5}$ in dry air at the same total pressure and electric field.

On the assumption that the secondary ionization mechanism is attributable to photoelectric action at the cathode, as is generally considered to be the case in air at low values of E/p, then it is possible that the observed large reduction in the secondary ionization coefficient may be caused by the absorption of photons by the water vapour present. Its value may then be expected to vary approximately according to the relation:

$$\gamma = \gamma_0 \exp(-\mu p_w d)$$

where γ_0 is the value of γ at $p_w = 0$, p_w is the partial pressure of water vapour in millimetres of mercury, μ is the absorption coefficient at $p_w = 1$ mm. mercury and d is the gap-length in cm.

In order to check whether this relation holds in the case of humid air, the values of $\ln\gamma$ have been plotted as a function of $p_w d$, as shown in Fig. 1. The circled points denote the values of $\ln\gamma$ at different partial pressures of water vapour, up to 15 mm. mercury, in air at a total pressure of 150 mm. mercury. The crossed points denote the values at several gap-lengths, ranging from 1·3 to 4·2 cm., in air at a total pressure of 150 mm. mercury containing 9 mm. mercury pressure of water vapour. Both sets of points are roughly collinear, as is to be expected if photoabsorption is affecting the secondary emission from the cathode. The approximate value of the absorption coefficient, as determined by the slope of the line through the points, is $\mu \sim 0 \cdot 2$ cm.$^{-1}$ at $p_w = 1$ mm. mercury.

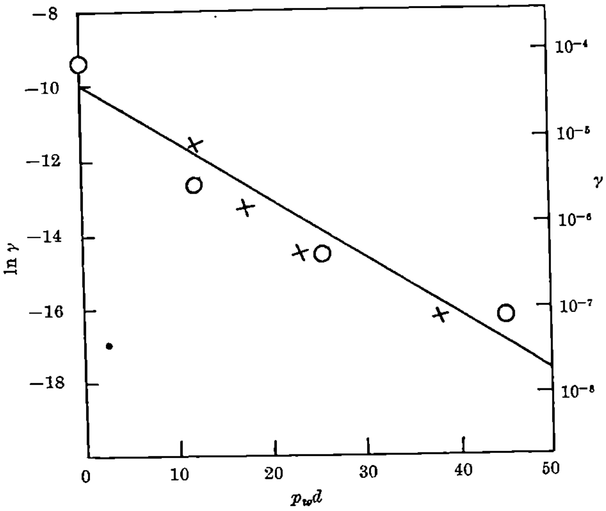

Fig. 1

Usually variations of the secondary ionization coefficient in Townsend discharge studies have been explained by consideration of changes in cathode work function, possibly caused by oxide layers or by adsorption of oxygen and other gases on the cathode surface. There is no doubt that surface conditions greatly affect it, and it is possible that in humid air a layer of water on the cathode surface could be responsible for the large fall in secondary emission. But the observation that the coefficient varies roughly exponentially with $p_w d$ suggests strongly that photoabsorption may also be an important factor in determining its value in humid air. This would not be inconsistent with other evidence as, for example, in Geiger counters, where absorption in methane has been found to reduce secondary photoelectric emission from cathodes. According to Weissler[2], absorption in methane does not occur at wave-lengths greater than about 1400 A., whereas in water vapour absorption is observed at wave-lengths up to about 1900 A. Raether[3] has also reported greatly reduced values of the secondary ionization coefficient in gases containing methane or alcohol.

Even in the absence of water vapour, it is possible that photoabsorption may affect the values of the coefficient of secondary ionization. The results for dry air show a steady fall in γ with decreasing value of the product of gas pressure p and the breakdown gap-length d. When the values of lnγ are plotted as a function of pd, over the range 100–600 mm. mercury × cm., a roughly linear relation is obtained with a slope giving $\mu \sim 8 \times 10^{-3}$ cm.$^{-1}$ at $p = 1$ mm. mercury. The result is complicated by the fact that the magnitude of E/p at breakdown increases with decreasing values of pd. Nevertheless, the suggestion that absorption may affect the coefficient of secondary ionization even in dry air does not appear unreasonable if one notes that, according to Weissler[2], absorption occurs in oxygen at wave-lengths up to about 1700 A.

The above preliminary views are put forward tentatively as a possible explanation of the variations observed by Prasad and Craggs in their measurements of the secondary ionization coefficient. As their experiments were not designed to examine directly the effect of absorption on the secondary ionization coefficient, the deductions that can be made based on their results are limited. There does appear to be sufficient evidence, however, to indicate that absorption may be an important factor in determining its value in air at higher pressures, particularly in the presence of water vapour, and further specially designed experiments are required to investigate the effect.

If the value of the secondary ionization coefficient does in fact fall to a value less than about exp(−18), that is, $\gamma < 10^{-8}$ approximately, the point arises as to whether the Townsend mechanism will still determine the onset of a spark at the minimum breakdown potential. For the multiplication in an avalanche will then be sufficient, greater than about exp(18), to produce a space-charge field of the order required to cause the transition from a single avalanche to a streamer, as observed in cloud-chamber experiments.

I acknowledge the permission of Prasad and Craggs to refer to their results before publication, and also the support given to this work by the Electrical Research Association, at the request of which the studies of ionization in humid air have been made.

RADIOBIOLOGY

Uptake of Strontium by Pasture Plants and its Possible Significance in Relation to the Fall-out of Strontium-90

Vose and Koontz[1] have lately compared the absorption of strontium-90 and calcium by six species of clover and six species of grass grown in pots containing three contrasting soil types. Their results support the conclusion, previously advanced on less complete results[2], that plant species differ little in the manner in which they distinguish between strontium-90 and calcium. It is well known that the calcium content of clovers is usually higher than that of grasses. Thus, as Vose and Koontz have noted, the absorption of strontium-90 from uniformly contaminated soil will lead to higher concentrations of strontium-90 per unit weight of tissue in clovers than in grasses.

While there can be no disagreement with the results of Vose and Koontz, their conclusion, "It is apparent that if the strontium-90 level in milk should ever rise to a level which, maintained over a period of time, might give cause for concern, it would be desirable to restrict dairy cows to an all-grass diet", appears open to question since :

(1) It is well established that when cattle are fed on a normal diet the ratio of strontium-90 to calcium in their milk depends primarily on the ratio of strontium-90 to calcium in their total diet, being approximately one-seventh of that quantity[3]. Vose and Koontz have shown that the ratios of strontium-90 to calcium in grass and clover grown on uniformly contaminated soil are similar; thus there are no grounds for postulating that the contamination of milk will change when freely grazing cattle are supplied with clover as opposed to grass.

(2) The view that the present levels of strontium-90 from world-wide fall-out in milk are due primarily to it lodging directly on the aerial tissues of plants

and not entering the soil[3] has lately received strong support from the observation of high ratios of strontium-89 to strontium-90 in milk[4,5]. There is no evidence that the aerial entrapment of strontium-90 by clovers exceeds that by grasses; thus the higher calcium content of clovers could lead to a lower ratio of strontium-90 to calcium in clovers than in grasses when aerial contamination is important.

(3) In so far as the contamination of pasture species with fall-out is due to absorption from soil, it is most important to consider the depth from which plant roots absorb their nutrients; a particular reason for so doing is the fact that the major part of the strontium-90 which enters undisturbed soil from fall-out is retained in the upper 5 cm. of soil[6]. Pasture grasses are relatively shallow-rooted while the root-systems of some legumes, notably lucerne, extend to considerably greater depths. Experimental results accord with the view that in these circumstances the ratio of strontium-90 to calcium is least in the more deeply rooted species[7]. For this reason experiments in pot culture, such as Vose and Koontz have described, do not necessarily indicate the situation which will occur under field conditions.

Thus, whereas when plants absorb strontium-90 from uniformly contaminated soil the balance between grass and clover in pastures appears unlikely to be an important factor in determining the strontium-90 content of milk, the presence of clovers in pasture may, under other circumstances, reduce, rather than enhance, the strontium-90 content of milk.

No final statement can yet be made on many aspects of this subject, which is under intensive examination in a number of laboratories; at present, however, there appear to be no valid grounds for suspecting that the presence of clovers in contaminated pastures is likely to increase the radiation dose to the population.

Separation of Strontium-90 from Calcium in Milk

Attention has recently been directed to the use of ion-exchange methods for alkaline earth separations and to the application of these techniques in the determination of radiostrontium in biological materials[1,4]. The measurement of environmental levels of radionuclides often necessitates the use of comparatively large samples of biological material and involves, in the case of liquid milk, a tedious evaporation procedure[2]. In an attempt to meet the need for a more convenient approach, a study was made of the extent of exchange, on cationic resin columns, of calcium and strontium absorbed from milk passed directly on to the columns.

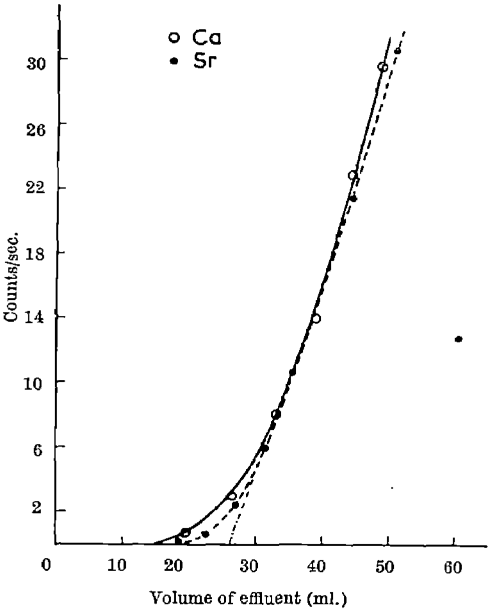

Fig. 1. Calcium, ○, and strontium, ●, breakthrough. Flow-rate, 0·14 ml./cm.^{2}/min.; temperature, 22° C.; column-length, 7·5 cm.

Whole milk samples, in which the natural calcium and strontium were 'spiked' with calcium-45 (0·25 MeV.β) and strontium-85 (0·51 MeV.γ), were run on to columns of a cationic exchange resin ('Zeo Karb' 225, 50–100 mesh, sodium form) and measurements were made of the β- and γ-activities in known volumes of the effluent. The breakthrough capacity for calcium, as indicated by a significant rise in counting rate (Fig. 1), corresponded to the value expected on the basis of capacity determinations carried out by potentiometric titration with sodium hydroxide. Since the ratio of calcium to total strontium (that is, natural strontium and strontium-85) in the milk is high, the resin capacity will be measured primarily by the retention of the calcium component. The observed equality of capacity for the two ions indicates removal of strontium by the large excess of calcium. For volumes of milk containing insufficient calcium to produce resin saturation, gravimetric analysis on influent and effluent solutions showed a quantitative retention of calcium (experimental error ±1 per cent). From parallel estimations of the casein content[3] it was concluded that there was zero retention of casein (experimental error ±2 per cent) indicative of complete breakdown of the calcium–casein complex.

Investigation of the elution characteristics for absorbed calcium and strontium was made using ethylenediamine tetraacetic acid as elutriant. Variations in the eluate of the specific activity of calcium-45 and strontium-85 added to the milk were observed in small-volume fractions collected at defined intervals, and also by continuous monitoring of the eluate passing through a flow counter (20th Century Electronics). The results, illustrated in Fig. 2, for elution at *p*H 8 showed good recovery (>90 per cent) of both calcium and strontium fractions. Further tests, using a range of different *p*H values for the elutriant, gave results in keeping with those described by Davis[1]. No interference with

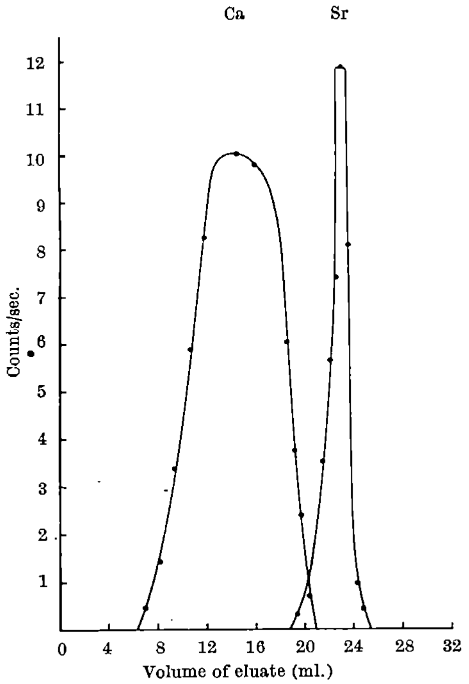

Fig. 2. Separation of calcium and strontium from 1 ml. of milk. Eluting solution : 1 per cent tetra sodium salt of ethylene diamine tetraacetic acid. *p*H 8. Flow-rate, 0·17 ml./cm.²/min. ; column-length, 16·5 cm. ; temperature, 22° C.

column operation was experienced from the milk-fat component, and the resin was readily regenerated for further use. These techniques may therefore be applied satisfactorily to the separation of calcium-free strontium in high yield directly from liquid milk.

BIOCHEMISTRY

Position of the Fatty Acids in Cardiolipin

Evidence was obtained previously[1-3] that cardiolipin is composed of two phosphoric acid, three glycerol and four fatty acid residues. According to this structure the polyglycerophosphate skeleton (1) has five hydroxyl groups available for esterification.

$$CH_2OH.CHOH.CH_2O.P : O(OH).CH_2O.CHOH.CH_2O.P : O(OH).CH_2O.CHOH.CH_2OH \quad (1)$$

The position of the fatty acids has now been ascertained by identification of the fragments obtained on hydrolysis of cardiolipin in conditions in which splitting of the phosphoric diester bonds take place preferentially with little rupture of the fatty acid ester bonds.

Cardiolipin (620 μmoles phosphorus), prepared from ox heart muscle by the method of Faure and Morelec-Coulon[4], was heated 90 min. in 50 ml. 90 per cent (v/v) acetic acid at 100° C., and after removal of the acetic acid *in vacuo* the water-soluble and ether-soluble fractions were separated. The ether-soluble fraction contained 68 per cent of the total glycerol, 19 per cent of the phosphorus and 98 per cent of the total fatty acids, only 5 per cent of which were free. By chromatography on silicic acid according to Borgström[5] 76 per cent of the fatty acids were recovered in the diglyceride fraction (485 μmoles ; molar ratio fatty acid–fatty acid ester–glycerol–phosphorus, 1·92 : 1·96 : 1·0 : 0 ; 1·7 double bonds/mole fatty acid) ; by periodic acid oxidation, not more than 2 per cent of this fraction was present as monoglyceride. The remaining fatty acids and the ether-soluble phosphorus were recovered in phosphatide fractions in partly degraded forms (phosphorus–glycerol–fatty acid, 1 : 1·1 : 2·2).

The water-soluble fraction of the hydrolysate contained 80 per cent (500 μmoles) of the phosphorus and 32 per cent (295 μmoles) of the glycerol, combined in a form hydrolysable by phosphomonoesterase ; not more than 10 per cent of the phosphorus, however, was present as glycerolmonophosphate, as estimated by Burmaster's method[6], and no free glycerol was detected. On fractionation 80 per cent of the water-soluble phosphorus was recovered as a barium salt sparingly soluble in water, corresponding in composition to barium glyceroldiphosphate (phosphorus–glycerol–barium, 2·0 : 1·06 : 2·2).

The main products of hydrolysis were therefore glyceroldiphosphate and diglycerides in molar proportion 1 : 2. These results are incompatible with the structure proposed for cardiolipin by Pangborn[7] (a chain of four glycerol and three phosphoric acid residues, in which all six available hydroxyl groups are acylated), which entails the formation on hydrolysis of free fatty acid in proportion to the water-soluble phosphoric ester formed. The results are consistent with a structure for cardiolipin as a derivative of 1, in which the terminal glycerol residues are esterified as diglycerides, leaving a free hydroxyl group on the middle glycerol residue.

Differential Response of Human Serum Cholinesterase Types to an Inhibitor in Potato

Differences in the degree of inhibition of the activity of human serum cholinesterase (pseudocholinesterase) produced *in vitro* by the local anæsthetic dibucaine (nupercaine) make it possible to classify individuals into three distinct types according to the character of the cholinesterase present in their serum[1]. These types are inherited, and are thought to be determined by a pair of allelic genes each of which is responsible for the synthesis of a distinct form of

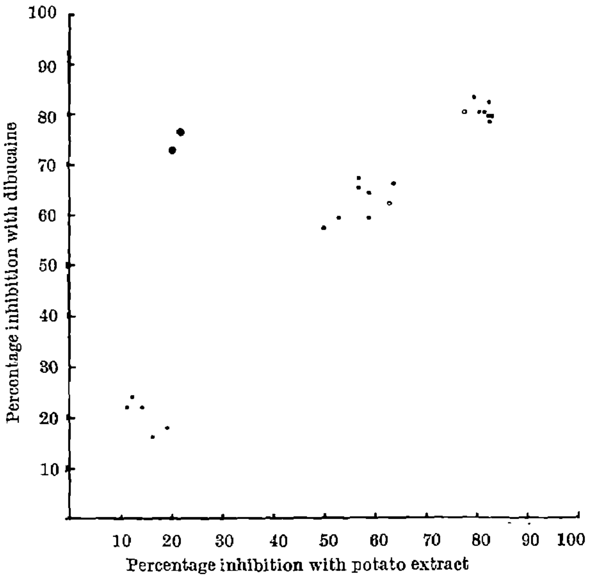

Fig. 1. Relation between percentage inhibition with dibucaine and with a potato-peel extract of pseudocholinesterase in plasmas from 21 different individuals

serum cholinesterase[2]. The two types of homozygotes each have only one of these esterases in their serum, while the heterozygote is believed to have both of them in about equal amounts[3]. The classification of the three phenotypes may be achieved by a number of cholinesterase inhibitors besides dibucaine[3]. However, there also exist certain cholinesterase inhibitors, such as tetraethylpyrophosphonate and di*iso*propylfluorophosphonate which fail to discriminate between the three types, presumably because their mode of action is different[3].

Orgell, Vaidya, and Dahm[4] have recently demonstrated that aqueous extracts of a number of solanaceous plants are capable of inhibiting human serum cholinesterase. It was of interest to see whether or not this common naturally occurring inhibitor acted differently on the three genetically determined phenotypes. A convenient source of this inhibitor is potato, and in the present experiments extracts of potato peel were used because it had been shown that the concentration of the inhibitor was considerably greater in the peel than in the inner part of the tuber.

A series of plasmas from individuals of the three cholinesterase phenotypes were used as a source of the enzymes. They had been typed according to the method of Kalow and Genest[1], using a 1-in-100 dilution of plasma, with 5×10^{-5} *M* benzoylcholine as substrate, 10^{-5} *M* dibucaine as inhibitor, in *M*/15 phosphate buffer *p*H 7·4. The reactions were followed spectrophotometrically at 240 mμ. The percentage inhibition obtained under these conditions was 77–83 per cent for the so-called 'usual' phenotype, 53–67 for the 'intermediate' phenotype, and 16–24 for the 'atypical' phenotype. The plasmas of the uncommon 'atypical' phenotype were mainly obtained from individuals who had been found to be unusually sensitive to the muscle relaxant succinylcholine when this was administered during anæsthesia. The individuals of the 'intermediate' phenotype were identified either in the course of studies of the families of the 'atypical' individuals or during random population surveys, where they constitute about 3 or 4 per cent of all people tested.

In the experiments with the potato extract the same procedure was adopted as mentioned above except that the extract was used as inhibitor in place of the dibucaine. The extract was prepared by macerating 85 gm. of potato peel in 300 ml. of water, and then filtering through gauze. A 1-in-100 dilution of the filtrate in *M*/15 phosphate buffer *p*H 7·4 was used as the inhibitor.

Results from a typical experiment using sera of 8 individuals with the 'usual' phenotype, 8 with the 'intermediate' phenotype, and 5 with the 'atypical' phenotype, are shown in Fig. 1. It is apparent that the potato inhibitor discriminates between the three groups just as sharply as does dibucaine, and there is a good correlation between the two sets of inhibition values. Several different batches of potatoes were tested with the same kind of results. Although the concentration of the inhibitor appears to vary slightly from batch to batch, clear discrimination of the three types was obtained in each case using a 1-in-100 dilution of the extract prepared as above.

The nature of the serum cholinesterase inhibitor in potato is not yet known. However, the occurrence in a common foodstuff of a substance which behaves differentially with the three serum cholinesterase phenotypes raises the question as to whether it may not be connected in some way with the genetical polymorphism determining the occurrence of alternative forms of serum cholinesterase in human populations.

An Alteration in the Excretion of Free Serine in Urine from Irradiated Humans

A number of investigators have been interested in the urinary excretion of amino-acids following total-body irradiation[1]. No one has used the quantitative column procedure of Moore, Spackman and Stein[2]. This preliminary communication is based on their procedure.

In June 1958 eight workmen were accidentally exposed to total-body gamma and neutron irradiation at one of the U.S. Atomic Energy Commission's installations in Oak Ridge. These men were studied at the Medical Division of the Oak Ridge Institute of Nuclear Studies. During the first 16 days the clinical manifestations of irradiation were minor, and the patients were ambulatory and ate well. There was a slight gain in weight during this period.

Urine was refrigerated (about 5° C.) after it was voided and, when a 24-hr. collection was complete, the volume was measured and aliquots for various procedures taken. As soon as the measurement and sampling was complete, all specimens were stored in the deep-freeze about (−15° C.) until they were analysed. Aliquots (2 ml.) of filtered urine were analysed without desalting. A commercial model of the automatic apparatus of Spackman, Stein and Moore[3] was used. Other analyses and analyses of hydrolysed urine[4] were done with the fraction-collector method[2].

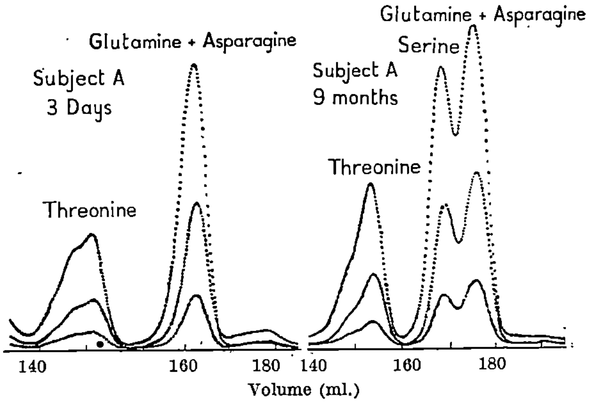

Fig. 1. Part of a recorder tracing of ninhydrin amino-acid colour taken from analyses of urinary amino-acids excreted by a man who was accidentally exposed to 365 rad of whole-body gamma and neutron irradiation. Serine is absent from the urine excreted 3 days after exposure

Among the most interesting results is the decrease in urinary excretion of free serine. This decrease is illustrated in Fig. 1. An analysis of a sample of urine excreted nearly nine months after the accident that shows the presence of free serine is included for comparison. Free serine was decreased even on the first day after irradiation and was apparently absent from this patient's urine three days after exposure. Traces only were excreted on the second and tenth days after irradiation. On the fourth and sixteenth days no serine was excreted. Serine was present in the urine after acid hydrolysis.

Serine was decreased but not absent from urine excreted by a child with leukæmia during the second day after 800 r. total-body irradiation. This irradiation was from a cobalt-60 source and, therefore, pure gamma. In contrast, there was a considerable neutron component in the accidental irradiation.

We do not have analyses of plasma and, therefore, do not know whether the reduced serine excretion is a renal effect or whether there is a change in the intermediary metabolism of this amino-acid in irradiated humans.

Mucoprotein of Bronchial Mucus Gel

In the absence of acute infection, the excessive bronchial secretion in chronic bronchitis is mucoid and owes its viscidity to a gel structure. This is apparent as an oriented fibrous network in the polarizing and electron microscopes[1-3], and there is a yield-value for disruption of the gel[2-4]. Mucoprotein can be isolated in yields of about 60 per cent of the total nitrogen by the procedure of Curtain and Pye[5], and has the composition shown in Table 1. Mannose and galactose are also constant constituents[1-3].

Table 1. The Composition of Bronchial Mucoprotein, as Percentage of Dry Weight

Constituent	Gm. percentage of dry-weight $M \pm S.D.$ (13 samples)
Nitrogen	8·6 ± 1·1
Total reducing sugar, expressed as glucose	19·5 ± 4·9
Hexosamine	6·1 ± 1·7
Fucose	5·1 ± 1·3
Sialic acid	4·2 ± 1·3
Bound sulphate as sulphur	0·0 – 0·2
Total phosphorus	*c.* 0·25

The viscous solutions are opalescent and gelatinous at concentrations above 1–2 per cent. The ultraviolet absorption in water or 0·1 *N* hydrochloric acid, due to aromatic amino-acids, has a maximum at 270–275 mμ (ε(N) about 190), with less scatter in 0·1 *N* sodium hydroxide and 280–284 mμ maximum (ε(N) about 110). On paper electrophoresis at *p*H 8·6 most of the material moves towards the anode as a peak giving reactions for protein and polysaccharide; but small fractions run in advance and remain at the origin. Boundary-electrophoretic results are comparable; there is no gross heterogeneity and less negative charge at *p*H 4·5 than at 8·5. The composition and properties are similar to those found by Brogan[6] for mucoprotein in the insoluble fraction after acid-peptic digestion of acetone-dried sputum.

In Ostwald viscometers there is an exponential relationship of relative viscosity to concentration up to 1 per cent (w/v). Although this is similar to deoxyribonucleic acid, there is no evidence for more than traces of this substance in the mucoprotein, and deoxyribonuclease does not affect the viscosity in the presence of magnesium ions. The intrinsic (limiting) viscosity of the mucoprotein has been determined for dilute, salt-free solutions (0·001–0·025 gm. protein/100 ml.), using Ostwald viscometers B.S. 1 and 2 at 25° C., and applying a kinetic energy correction to No. 2. Non-Newtonian at higher concentrations, solutions of mucoprotein below 0·02 gm. protein/100 ml. give comparable viscosities at different rates of shear. Plotting the reduced specific viscosity (η_{sp}/c) against concentration (c) and extrapolating fitted lines to zero concentration, the values for intrinsic viscosity are 8·1 (± 0·07) from viscometer 1, 8·8 (± 0·57) from viscometer 2, and do not differ within the limits of the sampling errors[7]. The partial specific volume is 0·69 by pycnometry. This gives an average viscosity increment of 1225, corresponding to an axial ratio[8] of about 150. Although this has little precision, since hydration is unknown, orientation of flow is likely to have occurred, and the electron-microscope suggests flexible chains and a greatly elongated molecule is indicated. Similar results were obtained by Curtain[9] for urinary mucoprotein.

Physical differences exist between bronchial and urinary mucoproteins. Curtain[9] found that solutions of the latter increase in viscosity with increasing ionic strength; precipitation is maximal in 0·58 *M* sodium chloride[6,10]. Very low concentrations of ions lower the viscosity of bronchial mucoprotein; with sodium chloride, viscosity is minimal at 0·04 *M*, increasing very slightly up to 4 *M*, without precipitation. The behaviour on centrifugation suggests modification of a gel structure. The aqueous 'solutions' are stable on standing at 5° C. (though occasionally an insoluble syneresed coagulum separates), but a loose gelatinous deposit forms with quite low centrifugal force (about 60 per cent of the protein

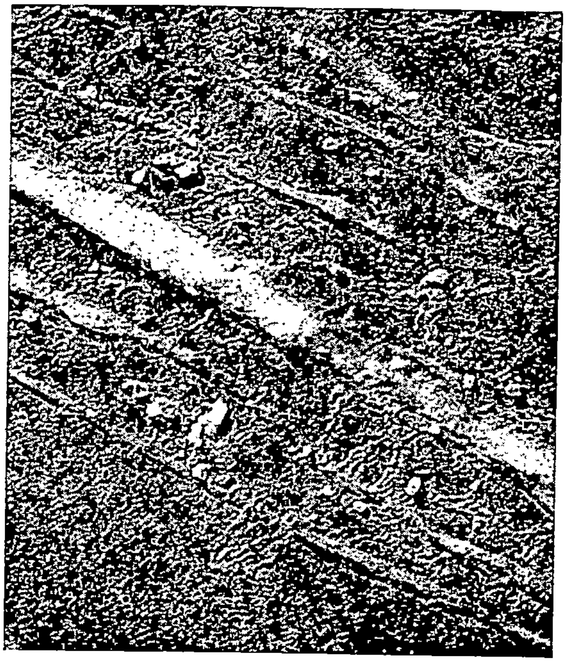

Fig. 1. Electron-micrograph of bronchial mucoprotein, shadowed with gold–palladium. (× 22,500)

at 9,000 r.p.m. for 1 hr.); in 0·15 *M* sodium chloride, more than 75 per cent of protein deposits in compact form. These deposits redisperse readily. Agents which modify hydrogen-bonding cause a fall in viscosity comparable to dilute salts, but very little deposits on centrifugation; for example, 6 *M* urea, 3·2 *M* guanidine hydrochloride, and particularly 8 *M* lithium bromide. In the ultra-centrifuge at speeds between 4 and 50 × 10^3 r.p.m., and at protein concentrations of 0·2 and 0·02 gm./100 ml. of 0·04 *M* sodium chloride, the concentration of the bulk of the solution diminishes rapidly, but with little movement of the peak. Gel deformation in the centrifugal field may well account for this. Tamm, Bugher and Horsfall[11] obtained $S_{20} = 29 \cdot 5$ for urinary mucoprotein and molecular weight $7 = 10^6$; however, there is likely to be a range of molecular size in this material also[10].

The bronchial mucoprotein forms oriented inclusions in crystals of sodium chloride[1,12]. By electron microscopy, the fibrils range in diameter from 0·1–0·2μ to 400 A. Between these, smaller, flexible micro-fibrils are seen (Fig. 1), and measurement of gold–palladium-shadowed preparations indicates that these are ribbon-like with mean cross-sectional dimensions, 304 A. wide by 74 A. thick, but occasionally about half this size. Although certainly composed of several molecular units, these approach the fundamental dimensions for a number of stable fibriform bodies[13]. A beaded appearance in the smaller micro-fibrils possibly indicates sub-units. There are similarities between the micro-fibrils and those of the urinary mucoprotein of Porter and Tamm[14].

In conclusion, it seems that the gel-structure of bronchial mucus is still present in the mucoprotein 'solutions' derived from it.

Note added in proof: Recent electron-microscopic evidence indicates breakdown of the gel-structure into short, rigid sub-units in 8 *M* lithium bromide.

We are grateful to Drs. R. Markham and E. M. Shooter, and to Prof. R. D. Preston for facilities for ultra-centrifugal, electrophoretic and electron-microscopic studies, and to the Peel Trust for a grant.

Phosvitin in the Serum of the Hen

A PHOSPHOPROTEIN fraction appears in the serum of the hen in association with the onset of laying[1,2] or in the serum of the immature bird on treatment with œstrogen[3]. It can be shown by zone electrophoresis on filter paper that two new major protein fractions appear in the serum on œstrogenization, one of these being specially rich in protein phosphorus[4]. The demonstration by Mecham and Olcott[5] of the existence of phosvitin in egg-yolk, and the view that yolk constituents are synthesized in the liver and transferred thence to the ovary in the blood plasma, prompted us to examine the blood of the hen for presence of phosvitin.

Four laying hens were each given 2 mgm. œstradiol benzoate per day for 5 days. The birds were then bled and 200 ml. serum was recovered. Crude lipovitellin complex was precipitated by bringing the serum to *p*H 5·3 and then adding an equal volume of distilled water. The precipitate was separated on the centrifuge, re-dissolved in 1 per cent sodium chloride and re-precipitated by ten-fold dilution with distilled water. The precipitate was worked up for phosvitin by the method of Joubert and Cook[6] as though it were egg-yolk, with the exception that an international refrigerated centrifuge Model *PR*1 was used instead of a high-speed centrifuge as used by Joubert and Cook. The method of Joubert and Cook avoids complications introduced by ether extraction.

After the final dialysis, the water-clear supernatant yielded, on freeze-drying, 150 mgm. of a white protein that contained 10·1 per cent phosphorus and 12·3 per cent nitrogen. The protein behaved as a single component and displayed the same mobility on paper electropherograms as did samples of phosvitin prepared from egg-yolk by the same technique, and gave no lipid stain.

We believe that this result represents the first occasion on which phosvitin has been identified as a constituent of the hen's blood. We consider further that the slow-moving 'PP' lipoprotein fraction, rich in protein phosphorus, on electropherograms of sera of œstrogenized and laying birds[4] probably represents a lipovitellin–phosvitin–γ-livetin complex in the sense in which this term is used by Joubert and Cook[6]. The 'PP' fraction was originally distinguished by the use of methanolic veronal buffer, but more recently we have been able to distinguish it by zone electrophoresis in aqueous buffer (*p*H 8·6, μ 0·05). The second, somewhat more mobile, lipoprotein fraction ("fraction 8" of Vanstone *et al.*[7]) presumably corresponds mainly to lipovitellenin.

We wish to thank the Agricultural Research Council of Quebec for its support of this project through a grant-in-aid of research. It is hoped to publish a fuller account at a later date.

Basic Substances as Synergists for Fat Antioxidants

ADDED fatty acids decrease the effectiveness of a number of antioxidants in marine and other oils and fats[1]. It has now been demonstrated that many oil-soluble basic substances may act as synergists. For example, a primary amine (octadecylamine, ODA), a secondary amine (proline), and a tertiary amine (tri*iso*octylamine, TOA) provided unexpectedly great protection against oxidation to oils containing added 6-ethoxy-2,2,4-trimethyl-1,2-dihydroquinoline (EMQ, 'Santoquin'), whereas in the absence of the last-named they conferred only slight or no protection at the same levels (Table 1).

The effects of the various basic additives differed with each antioxidant. For example, in general they were synergists to 2-tertiarybutyl-4-methoxyphenol (BHA) but had no effect or acted as antagonists to 2,6-ditertiarybutyl-4-methoxyphenol (BHT). They were also more effective with γ-tocopherol than with α-tocopherol. In this respect they have been found useful in differentiating the various tocopherols with regard to antioxidant effectiveness.

Substrates also modified the respective activities. With the samples of highly purified trilinolein available to us (Hormel Foundation), octadecylamine acted as an antagonist to α-tocopherol and synergist to γ-tocopherol, whereas in menhaden oil octadecylamine was synergistic with both.

Proline was particularly effective in vegetable oils, probably acting in conjunction with the natural antioxidants. For example, samples of a refined olive oil containing 0, 0·025 and 0·05 per cent added proline had induction periods at 60° C. of 4, 12 and 23 days, respectively.

The synergistic effects of phospholipids and of some amino-acids on phenolic type antioxidants have been recognized for a number of years[2]. It appears likely that these effects may be mediated through the basic groups of such compounds, modified by solubility, heavy-metal chelating, and other properties. With respect to phospholipids, this contrasts with a previous suggestion[3] that the phosphate portion of the molecule was primarily involved.

Table 1. EFFECT OF MIXTURES OF ANTIOXIDANTS WITH BASIC SYNERGISTS ON MENHADEN OIL AND TRILINOLEIN

* Induction periods were determined by the gain in weight method recently described (ref. 4). 10-ml. beakers containing 200 mgm. substrate plus 0·5 μ*M* of antioxidant and 2·5 μ*M* of basic additive were incubated in a draft oven at 50° C., cooled and weighed once daily (to 0·1 mgm.). The end of the induction period was usually readily detected by a rapid gain in weight and arbitrarily fixed at the time at which the weight gain was 1 mgm.

† The menhaden oil was a commercial alkali-refined product treated to remove peroxides as follows: a 10 per cent solution in light petroleum ether was passed through a column of deactivated alumina and the solvent removed *in vacuo*.

‡ A preparation of yeast lecithin containing 1·89 per cent nitrogen, 4·1 per cent phosphorus, 0·03 per cent amino-nitrogen (D. J. Hanahan).

§ BHA is often designated 2 (or 3)-tertiarybutyl-4-methoxyphenol. The preparation which was used in much of this work contained at least 85 per cent of the 2-tertiarybutyl derivative. Similar results were obtained with the pure 2-isomer.

The progress of this work has been hampered by difficulties in obtaining reproducible runs. The results shown are, however, typical of a number of determinations. Details will be published elsewhere.

This work is supported in part by funds made available by the Saltonstall-Kennedy Act, administered by means of a collaborative agreement between the U.S. Fish and Wildlife Service and the University of California.

An Improved Method for preparing Pectate Gels

THE routine use of pectate gel media as an aid to the detection of bacteria causing soft rot of plant tissue has been restricted by the difficulty commonly encountered in their preparation. One of the most useful methods is that of Wieringa[1], who adopted the double-layer technique, consisting of a plate of calcium agar over which the pectate solution was poured. Diffusion of calcium ions from the agar brought about the formation of a gel.

In practice it has been found that convenient quantities of liquid pectate solution are difficult to prepare, as a weak gel forms on cooling and during storage. This gel frequently fails to liquefy uniformly on heating, and the resultant lumpy fluid produces unsatisfactory plates. Moreover repeated autoclaving of pectate solutions tends to lower the quality of the final gel.

The addition of disodium salt of ethylenediamine tetraacetic acid in low concentration to the pectate solution prevents the unwanted gel formation. This free-flowing liquid can be autoclaved normally and sterile stocks can be stored indefinitely without losing the ability to form a firm gel in the presence of sufficient calcium ions.

This appears to be due to the activity of the disodium salt as a chelating agent for the calcium ions present in the pectate. The high concentration of these ions diffusing from the calcium agar is sufficient to replace the calcium removed by chelation and, if in excess, to bring about adequate gelling of the pectate.

The procedure which has proved satisfactory in current work on soft rot pseudomonads can be summarized as follows. (*a*) Calcium agar base: peptone (Evans) 0·5, lemco 0·5, calcium lactate 0·5, agar (Davis) 1·5 per cent (sterilize at 15 lb. pressure). (*b*) Pectin solution: mix 2 gm. pectate powder with absolute alcohol to form a thin paste; make up with distilled water to 100 ml. and add 0·1 gm. disodium salt of ethylenediamine tetraacetic acid. Sterilize at 15 lb. pressure. The pectin solution is poured as a thin layer over a plate of the calcium agar (1 cm. deep). The gel sets firmly within 12–24 hr. at 27° C.

The pectate powder used was either 'Sodium polypectate' ('Exchange' brand obtainable from Sunkist Growers (Products, Ltd.), Ontario, California, and S. and S. Services. 72 Victoria Street, Westminster, London, S.W.1) or 'sodium pectate' (A.S.P. Chemical Co., Ltd., Bulstrade, Gerrard's Cross, Bucks).

Conversion of Caffeic Acid to Esculetin during Paper Chromatography

ESCULETIN was found in an extract of plant tissue which contained caffeic acid. The esculetin was not a natural product but was formed from caffeic acid during the paper-chromatographic purification procedures. This conversion was confirmed by two-dimensional chromatography of authentic caffeic acid.

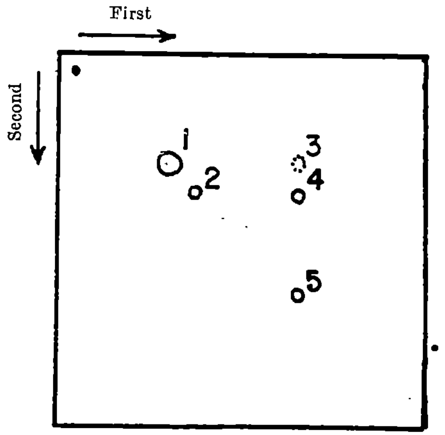

Fig. 1. Chromatogram of caffeic acid. Developing solvent: 5 per cent acetic acid in both dimensions

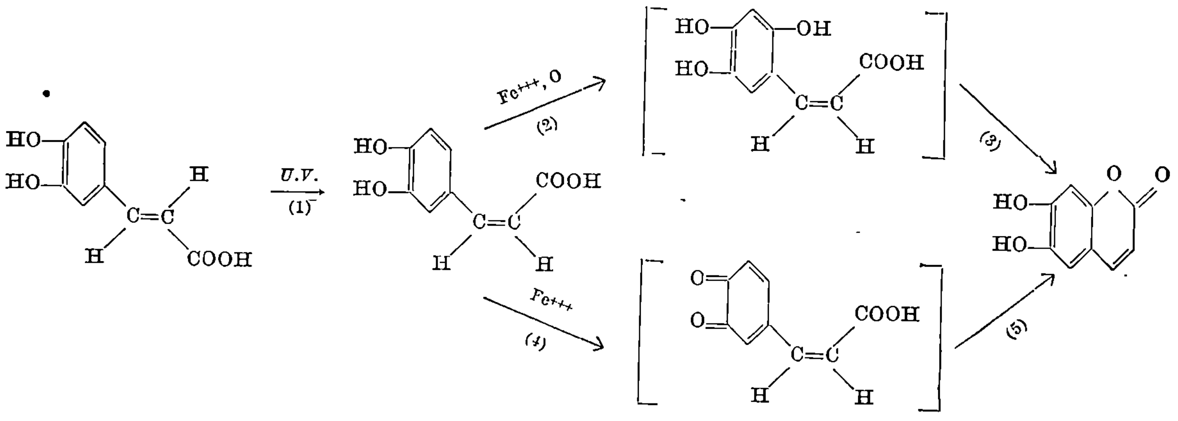
The fluorescent spots found on a two-dimensional chromatogram of caffeic acid using 5 per cent acetic acid as the solvent in both dimensions are shown in Fig. 1. When the chromatogram is developed in the dark on unwashed or water-washed chromatographic paper, only spot 1 is seen. If the caffeic acid is irradiated with a low intensity ultra-violet lamp for 5 min. at the origin before development, all five of the fluorescent spots are found. If chromatographic paper which has been washed with 0·001 *M* ethylenediamine tetraacetic acid is used, only three of the spots, 1, 3 and 5, are found on the chromatogram of the ultra-violet-irradiated caffeic acid. If the paper washed with ethylenediamine tetraacetic acid is dipped into 0·01 *M* ferric chloride and dried, the developed chromatogram of the ultra-violet-irradiated caffeic acid has all five spots. The spots were identified as: (1) caffeic acid; (2) esculetin; (3) caffeic acid; (4) esculetin; and (5) caffeic acid.

The ultra-violet light converted a part of the *trans*-caffeic acid at the origin to the *cis*-isomer[1]. Chromatography in the first dimension separated the slower moving *trans*-isomer from the faster moving *cis*-isomer. In the second dimension, a small amount of the *cis*-isomer reverted to the *trans*-isomer (spot 3 is quite faint) and esculetin appeared. The formation of the esculetin from the *cis*-caffeic acid is an oxidative reaction requiring metal ions. Esculetin is not found on chromatograms which are developed on ethylenediamine tetraacetic acid washed chromatographic



paper. The conversion of *cis*-caffeic acid to esculetin could proceed through a hydroxylated intermediate or through a quinone. The hydroxylation reaction, step 2, is similar to the hydroxylation of phenols by an ascorbic acid–iron system studied by Undenfriend[2]. The lactone formation, step 3, is analogous to the spontaneous cyclization of *cis*-*o*-coumarin acid to coumarin[1]. An alternative mechanism involves oxidation to the quinone, step 4, with lactone formation by a Michael addition β to the carbonyl followed by aromatization, step 5. This is less likely, however, because Michael additions do not generally occur under mild acid conditions.

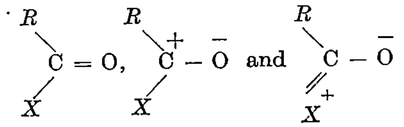
A Proposed Interpretation of Infra-red Spectral Changes occurring upon the Interaction of Polynucleotides

IT has been found that the sodium salts of polyadenylic and polyuridylic acids interact[1–4] with formation of a two-stranded helix[1] with a structure very similar to deoxyribonucleic acid. More recently it was observed that the infra-red spectrum[5] of the mixture of these two acids showed the following marked changes from the summation of the curves of the components: a 39 per cent reduction in intensity of the 1,627 cm.$^{-1}$ band and a 7 cm.$^{-1}$ shift to higher frequency; a decrease in peak height (because of strong overlap the band was not integrated) and an 11 cm.$^{-1}$ shift to higher frequency of the 1,661 cm.$^{-1}$ band. The interaction of the sodium salts of polycytidylic and polyinosinic acids[6] has now been observed in the infra-red[7] with the following result: a marked decrease in intensity of the 1,651 cm.$^{-1}$ peak of the sodium salt of polycytidylic acid (the intensities have not yet been put on a quantitative basis) and a 19 cm.$^{-1}$ shift to higher frequency of the 1,678 cm.$^{-1}$ peak of the sodium salt of polyinosinic acid.

It is possible that an understanding of these changes may be reached by taking into account the change in environment of the vibrating groups after interaction has occurred. A consideration of the helical structure of deoxyribonucleic acid[8,9] and of the polynucleotide pairs[1,6] reveals that the heterocyclic rings are covered on both sides by other such rings at a distance of about 3·4° A. This is no more than a van der Waals separation, and is insufficient to admit water molecules between the planes of the two rings. One result of this helical configuration is, therefore, that the dielectric constant of the immediate environment of the vibrating groups must be considerably diminished, even though water remains in the area which is not between the base pairs.

The purine and pyrimidine bases are hydrogen bonded to water before interaction and to other bases after interaction, but the hydrogen bonds existing after interaction should be stronger than those that existed before[10]. The observed spectral changes, thus, are probably not caused (directly) by the new hydrogen bonds since the usual effect of hydrogen bonding is to decrease frequency and increase intensity rather than the reverse.

The following qualitative considerations, on the other hand, suggest that the observed changes are consistent with a decrease in dielectric constant. The principal resonance forms of the carbonyl group[11] are:



Hydrogen bonding favours the dipolar forms with a resulting shift to lower frequency. A marked decrease in dielectric constant of the medium, however, should diminish the contribution of the forms involving a charge separation and result in a shift to higher frequency. A second result of a decrease in dielectric constant is that there should be a smaller change in dipole moment with the vibration of the bond responsible for the absorption and a consequent reduction in intensity. Experimental results in support of these expectations are cited below.

In studies of frequency and intensity changes in approximately a dozen solvents[12,13] (see also ref. 11), it has been shown that the carbonyl stretching bands show a general trend of increase in frequency and decrease in intensity as the dielectric constant of the medium is decreased. Thus, for example, the frequencies of several ketones increase 11–14 cm.$^{-1}$ on going from chloroform to hexane and 8–9 cm.$^{-1}$ on going from benzene to hexane. There are also 18–36 per cent and 15–20 per cent reductions in intensity for the same solvent changes. *NN*-Diethylacetamide[13] showed a frequency increase of 38 cm.$^{-1}$ for the first solvent change and 15 cm.$^{-1}$ for the second, with intensity reductions of 24 and 20 per cent, respectively. *NN*-Diphenylacetamide showed a similar trend for those solvents in which it was soluble. The directions and approximate magnitudes of these spectral changes are thus consistent with those observed with the polynucleotides. While there are undoubtedly other factors contributing to the observed spectral changes, it is suggested that the above-mentioned decrease in dielectric constant may very well be the most important cause.

OPHTHALMOLOGY

Regeneration of the Lens of the Eye in the Rabbit

In a recent communication, Chanturishvili[1] reports his re-investigation of the detailed embryology of the lens in Amphibia and refers to work on higher forms in his laboratory at Tiflis. He and his fellow-workers, in particular Sikharulidze[2], are of the opinion that the lens fibres are derived from cells which are neural in origin, and which require for the initiation of fibre production the products of the cytolysis of epidermal elements.

As a corollary of their view of lens development the Tiflis workers have introduced small fragments of cytolysing fœtal tissues into the lens capsules of adult animals from which all easily separable contents had been evacuated. They report that whereas simple evacuation without implant is followed by very little regeneration (the familiar aphakic state following the operation of extracapsular lens extraction), the addition of the implant is followed by the regeneration of a lens nearly normal in size and structure.

On a visit to Tiflis in 1955 one of us (P. G. 'E.) was enabled, by the courtesy of Prof. Chanturishvili, to see something of this work there. Later, Prof. Chanturishvili most kindly placed at our disposal, in the fullest possible detail, particulars of the techniques employed by him and his co-workers.

At Prof. Chanturishvili's suggestion, we repeated here the experimental implantation of cytolysing fœtal tissue taken from the lid commissure of a three-week embryo into the evacuated lens capsules of six normal rabbits according to the technique of Tamara Sikharulidze. We kept suitable control animals in which the lens capsule contents had been simply evacuated without implantation. This work was done because it was hoped that Prof. Chanturishvili would be able to attend the Oxford Ophthalmological Congress and to demonstrate this material of ours there. In the event, he was not able to do so, but these rabbits were demonstrated there by us in July 1958, 12 weeks after operation.

At that time there were marked differences to be seen between those evacuated lenses which had received implants and those which had not. Whereas the animals without implants showed the normal aphakic post-operative condition of collapsed and apposed capsular walls, those which had received implants showed inflated and in some cases spheroidal lens capsules, the contents and shape of which had a refractive power approximating to that of normal lens. This process of regeneration is continuing eleven months after operation.

Prof. Chanturishvili visited this Department in August 1958 and allowed us to examine his embryological preparations and generously presented us with material. He states that about 16 months are needed for full regeneration, but our most promising rabbits have lenses already little different from the normal in size. The iris can be seen to be supported by the convex anterior surface of the lens as in the normal eye, whereas in the aphakic controls the unsupported iris presents a concave surface to the observer.

Assessment of the structural and functional state of each lens in an ophthalmological sense has been made at frequent intervals by evaluation of the refractive condition of each eye as a whole by ophthalmoscopy and skiascopy. Whereas the normal unoperated eye in our rabbits is from zero to two and a half dioptres hypermetropic, the aphakic control eyes have consistently been found to be of the order of ten to fifteen dioptres hypermetropic. By notable contrast, the eyes which had received implants have been found, in the areas of incipient lens regeneration, to be comparable in refractive power to the normal as early as eight weeks after operation.

The progressive variations in shape and appearance of the lens capsule and its contents in each case have also been surveyed by frequent slit-lamp biomicroscopy. In every lens which received a fœtal implant the anterior and posterior capsule walls have become separated in part, and in some instances fully. The lens has assumed a progressively spheroidal shape. Relucence of the substance within the capsule suggests that it possesses optical properties comparable with those of a normal lens and differing from those of aqueous humour.

The approximately lenticular shape of the most successful examples and their relatively transparent and homogeneous contents make possible a satisfactory ophthalmoscopic view of fundus detail. Even in the best, however, there are some variations of optical density still remaining. These may possibly be ascribed to incomplete cytolysis of implanted material, or to incomplete removal of the original contents of the lens capsule. On the other hand, some of them may represent a stage in a process of regeneration not yet complete. Distortions of shape and incomplete separation of the capsule walls, which were found particularly in our first few operations, are probably due to faulty technique.

The preliminary observations reported here seem so far to confirm the findings of the Tiflis workers in the rabbit.

We propose to repeat our work here on a larger scale to allow the sectioning of regenerating lenses at all stages. It seems to us that this filling out of the capsule in so short a time may perhaps be ascribed to the secretion of a 'ground substance', in which fibres may grow later, more probably than to actual immediate growth of functional fibres.

Sikharulidze reports retarded but satisfactory regeneration of lenses in rabbits after the removal of cataracts induced chemically. At present we are engaged in a repetition of our work using rabbits which have received high doses of local irradiation.

PHYSIOLOGY

Induction of Arginase in Rabbit Epithelium by the Shope Rabbit Papilloma Virus

In studies of the mechanism of action of the Shope virus in causing papillomas on the skin of rabbits, comparative tests were made of active transport of amino-acids into papilloma cells and into normal and hyperplastic rabbit epithelium. The method used was that recently reported by Rogers and Woodhall[1].

Papilloma epithelium taken at intervals varying from 10 days to one month from the time of inoculation of the papilloma virus was cut into tiny pieces, the largest size of which was on the average of 0·25 mm. in diameter, rinsed in Ringer's solution, 50–100 mgm. amounts of tissue added to 1·5 ml. of a synthetic tissue culture media (Media 199, Difco), incubated for 2–20 hr. at 37° C., the cells and cell clumps centrifuged out of the media, the media chromatographed, and the relative amounts of amino-acids remaining determined semi-quantitatively with a Spinco analytrol densitometer. The chromatograms were made using butanol, 40 ; acetic acid, 10 ; water, 50 and aqueous phenol. Normal and hyperplastic skin were entirely similarly treated. The hyperplastic skin was of two sorts ; the 'spontaneous' variety associated with cyclic hair growth and that induced by several treatments of the skin with a 50 : 50 solution of turpentine and acetone. Experiments were done in both Kansas cottontails and domestic rabbits.

A number of differences in the relative amounts of amino-acids removed from the media, as well as differences in which amino-acids were removed, were found. This communication is concerned with only a seemingly qualitative difference relating to arginine uptake. In repeated experiments the papilloma tissue invariably has taken up large amounts of arginine. No demonstrable uptake of arginine has been found in the case of normal or hyperplastic skin. However, as this amino-acid is a common constituent of protein, the uptakes are probably merely too small to measure in this system. Table 1 depicts the results of a typical experiment.

Table 1. ARGININE (PER CENT) REMAINING IN MEDIA AFTER INCUBATION WITH PAPILLOMA OR WITH HYPERPLASTIC SKIN EPITHELIUM

	Period of incubation	
	2 hr.	20 hr.
Papilloma	25	10
Hyperplastic skin	100*	110†

* Equivalent to 0·07 mgm. arginine per c.c.
† Increase from cellular breakdown.

As a result of the above findings, together with the fact that ornithine was regularly found in the media exposed to the papilloma tissue and not at all in the media exposed to skin, it was decided to find whether arginase could be demonstrated in extracts of papilloma tissue and in extracts of normal and hyperplastic skin. The arginase was extracted, concentrated, and tested by standard methods outlined elsewhere[2]. 3 gm. of papilloma tissue were ground to a paste with sand and an extract then made. The concentrated dialysed solution was activated by incubation at 37° C. for 3½ hr., and 0·5 ml. was then added to 0·5 ml. of a solution of arginine (7 mgm. per cent) in barbital buffer at *p*H 9·6 and incubated at 25° C. for intervals ranging from 15 min. to 20 hr. The mixture was then chromatographed and the amount of arginine determined comparatively. Hyperplastic and normal skin mixed in about equal proportion were extracted and concentrated in parallel. In the experiment, the results of which are shown in Table 2, 15 gm. of combined normal and hyperplastic skin were used. In no experiment has any detectable arginase activity been found in extracts of domestic rabbit skin derived from adults or embryos in the last trimester of gestation despite the fact that much larger amounts by weight have been tested than from the Shope virus-caused papillomas, which contain this enzyme in large amounts. A trace of arginase activity has been found in wild rabbit skin extracts. However, wild rabbit skin is extremely thin and the preparation contained an estimated 25 per cent of tissue other than skin epithelium.

Table 2. COMPARATIVE ARGINASE ACTIVITY OF EXTRACTS OF PAPILLOMA AND OF NORMAL AND HYPERPLASTIC SKIN

	Arginine remaining after incubation period (per cent)		Ornithine after incubation (per cent)
	15 min.	20 hr.	
Papilloma extract	5·5	0	++++
Skin extract	120*	117*	0
Buffer plus arginine	100†	100	0

* Increase due to small amount of arginine present in concentrated dialysate.
† Equivalent to 0·07 mgm. arginine per c.c.

Only a trace of arginase activity has been detectable in a preparation of isolated and concentrated Shope virus containing 1·20 mgm. of protein nitrogen per c.c. incubated with 0·07 mgm. arginine per c.c. for 20 hr. The virus was isolated using the method of Beard, Bryan, and Wyckoff[3]. In view of the large amount of virus in this preparation, the arginase would seem most probably a contaminant rather than being an intrinsic attribute of the virus particles.

It is evident from these results that the Shope virus infection of epithelial cells is somehow inducing arginase in cells of a sort which contain no detectable arginase in their normal or hyperplastic state. One such means is that the presence of the virus in the cells induces or enables them to synthesize an enzyme new to them, arginase. Another possibility is that the virus induces a permease allowing the cells to concentrate arginine, the concentration of which in turn induces arginase. Either of these two possibilities would increase the metabolic efficiency of the cells. Might such an increase in efficiency be responsible for the overgrowth of these cells which is manifest as their neoplastic state ?

Oral Induction of Leukæmia in Mice

THE induction of leukæmia by parenteral inoculation of cell-free brain filtrates has been demonstrated[1,2]. Speculation as to the natural route of transmission of leukæmia led to the exploration of the leukæmogenic effect of whole brains and cell-free brain filtrates when given orally.

Swiss mice, approximately six weeks old, of both sexes, and *C3H* × 101 males were used. A 1 per cent concentration (w/v) of cell-free brain filtrates was prepared in the manner previously described[3], in which distilled water was used in place of physiological saline solution. The brain mince was prepared by forcing whole fresh brain through an 18-gauge needle with a syringe.

In experiment 1, Swiss mice were deprived of food and water for 24 hr. and then given cell-free brain filtrates as drinking water. Mice which received whole-brain mince were placed in individual cages and given approximately 0·5 gm. mince in a Petri

Table 1. Experiment 1

Material fed		No. leukæmic/No. fed
Brain mince	Non-leukæmic	0/25
	Leukæmic	4/25
Cell-free brain filtrate	Non-leukæmic	0/20
	Leukæmic	5/22

Table 2. Experiment 2

Material fed by intubation	No. leukæmic/No. fed
Non-leukæmic cell-free brain filtrate	0/25
Leukæmic cell-free brain filtrate	13/25

dish. Mice were allowed to eat or drink these materials for 24 hr. and then placed on regular diets. Results of this experiment are shown in Table 1.

In experiment 2 cell-free brain filtrates were prepared from the brains of *C3H* mice. *C3H* × 101 mice were lightly anæsthetized with ether. A No. 18 polyethylene tube was passed into their stomachs and through it 1 c.c. cell-free brain filtrate was injected. Results of this experiment are shown in Table 2.

In animals which developed leukæmia, the disease appeared within three to twelve weeks. Both the gross and microscopic results were similar to those previously described[1]. Identical leukæmias developed in seven out of ten mice inoculated intraperitoneally with 0·5 c.c. of the leukæmic cell-free brain filtrate used for feeding in experiment 1.

Brains of mice with orally induced leukæmia were later shown to be infective when the cell-free brain filtrate was given orally or intraperitoneally.

From the evidence presented, leukæmia in mice can be transmitted orally by either whole leukæmic brain or its cell-free filtrate. Investigators of leukæmia in mice should be aware of this possibility in the laboratory, where mice are caged together and where cannibalism occurs.

The influence of the gastrointestinal tract in the epidemiology of leukæmia remains to be elucidated.

Experimental Colloid Goitre produced by Thiouracil

Colloid goitres, resembling those occurring endemically in man, have been produced in the hamster by an iodine-deficient diet followed by repletion with this element after epithelial hyperplasia had developed[1]. It seemed possible that if proliferative activity of thyroid epithelial cells was produced in this species by other means, such as a goiterogen, colloid accumulation might occur when the stimulus was removed. Such would be in keeping with Marine's hypothesis of the pathogenesis of colloid goitre[2]. This has proved to be the case. The occurrence of colloid goitre in animals which had received thiouracil and allowed to recover from its effects may be helpful in our understanding of the pathogenesis of endemic goitre in man in cases where absolute iodine deficiency may not be a causative factor.

Hamsters weighing 100–125 gm. were fed diets of low iodine (2·5γ/100 gm.) or higher iodine (200γ/100 gm.) content which contained 0·3 per cent thiouracil. After subsisting on these regimens for varying periods of time up to 8 weeks the goiterogen was removed from the diet, after which the animals were allowed to live for varying intervals up to 2 months. At autopsy the thyroids were weighed and examined microscopically.

Extensive hyperplasia with loss of colloid accompanied by increased vascularity occurs within the first week after thiouracil administration. This progresses for the period during which this series of animals has been observed and conforms with the findings of others in the hamster[3,4]. The changes are more marked in animals on the low iodine intake. When the drug is removed from the diet, the follicles fill up with colloid and much of the epithelium becomes flattened, although sprigs of columnar cells are found projecting into the lumens. The degree of colloid deposition is related to the antecedent hyperplasia, that is, the time the animal received the goiterogen, together with the length of repletion. The follicles increase in size from their usual average of 45μ in diameter up to 100–150μ. The weight of the glands is increased tenfold or more.

The principal reason for this communication is to direct attention to the ease and rapidity with which diffuse colloid goitre may be produced by a goiterogen in the hamster. In our experience, comparable

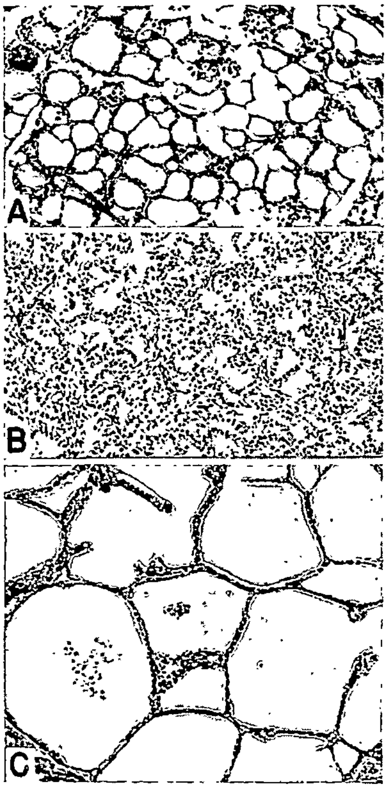

Fig. 1. Photomicrographs of thyroid glands. *A*, Normal; *B*, from an animal on low iodine–thiouracil-added diet for 20 days; *C*, from an animal comparable to *B* but off thiouracil for 3 weeks. (All × *c*. 84)

degrees of hyperplasia take a year to develop on an iodine-deficient diet[1].

Marine[5] expressed the belief fifty years ago that goitre was an iodine-deficiency disease. He viewed its pathogenesis as follows: iodine deficiency leads to hyperplasia which continues unless this element is administered; whereupon the gland fills up with excess colloid, a state representing "the nearest approach to normal glands that active hyperplasias can become". The role of the pituitary in this process is, of course, now recognized. The main difficulty in accepting Marine's hypothesis in its entirety has been that the structural alterations seen in the naturally occurring disease had not been produced in laboratory animals[6]. This is particularly true with respect to diffuse colloid goitre, although few investigators have tried to put Marine's hypothesis to the test. Most recent pathological studies on the thyroid have dealt with tumour production. Mackenzie[7] has summarized the story of experimental goitre with particular respect to the effects of iodine deficiency and goiterogenic agents, and points out that "with the judicious use of antithyroid drugs and thyroxine (or perhaps diet) we may be able to produce the elusive colloid goitre in the laboratory". Since this has been accomplished by iodine deficiency and goiterogens in the hamster it appears that pointed studies of other species, excepting perhaps the rat[7], will be of interest and throw further light on the pathogenesis of endemic goitre in man.

Variability of Content of Deoxyribonucleic Acid in *L*-strain Fibroblasts

It is well known and has been amply demonstrated that the deoxyribonucleic acid content of normal 'resting' mammalian cells in the host is constant from cell to cell and tissue to tissue. The germinal tissue is the single exception, having instead exactly half the quantity of acid. This has been felt to reflect the constant chromosome number of these cells.

In tissue-culture cells, however, conflicting evidence is at hand. Some work apparently demonstrates a constant level of deoxyribonucleic acid, while other investigations reveal changing content of the acid depending on the cultural circumstances. Simonovitch *et al.*[1] found that in their rotating suspension cultures of *L*-strain fibroblasts, the deoxyribonucleic acid content paralleled at all times the cell number. Their cultures were always seeded from a parent culture which was in the logarithmic phase of growth. Recently, Salzman has used HeLa cells to obtain different results. He finds that during the lag phase of these cells grown as monolayers on glass, there is doubling of deoxyribonucleic acid, ribonucleic acid and protein, while the cell number does not change. On the other hand, when these cells are grown in suspension cultures, ribonucleic acid and protein but not deoxyribonucleic acid rise before the number of cells[2].

In our work with *L*-strain fibroblasts in continuous agitation suspension cultures[3], we have made some observations which incorporate these apparently conflicting data. Fig. 1 illustrates the fact that, when a subculture is made from a parent culture which is old and in the stationary phase (reflected in a stable cell population and low values of protein per cell), the content of deoxyribonucleic acid per million cells in the subculture follows a sharply rising and falling curve: during the first day, the deoxyribonucleic acid almost doubles, while cell population remains unchanged. When, on the other hand, the subculture is seeded from a parent culture which is in logarithmic growth at the time of the transplant, the daughter culture immediately goes into logarithmic growth, and content of deoxyribonucleic acid per million cells remains constant throughout the log growth period. Protein content, also shown in Fig. 1, parallels the content of deoxyribonucleic acid in both instances. A lag phase can be produced at will in any culture by adjusting initial *p*H to 7·4.

If the constant deoxyribonucleic acid level of the cells seeded from cultures in logarithmic growth represents the basic chromosomal acid-level of these cells, then it is clear that the cells seeded from stationary cultures replicate deoxyribonucleic acid to almost twice the normal complement in the 24-hr. lag phase. Apparently in these latter cells, the stimuli for replication of deoxyribonucleic acid and for division have become disordered and out of phase during the stationary period, with the result that while replication of deoxyribonucleic acid proceeds, division does not. In most normal cells, it seems clear that replication of deoxyribonucleic acid occurs during the last half of interphase[4], and if these cells were synchronous in time of division, it would appear that the accumulation of deoxyribonucleic acid merely represents this pre-mitotic replication. However, multiple mitotic counts using aceto-orcein stain have demonstrated no evidence of such synchrony in our cultures. Furthermore, the cell count increases gradually in the first 24 hr. of logarithmic growth.

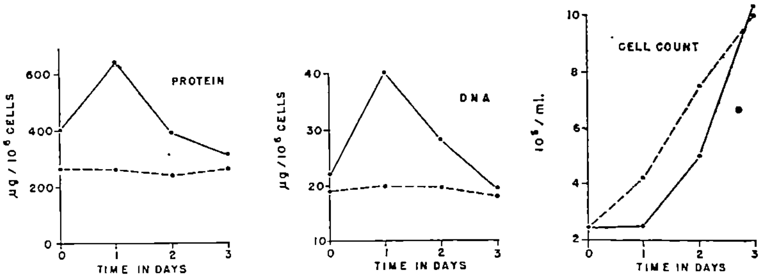

Fig. 1. Protein, deoxyribonucleic acid and cell count in fibroblast cultures. The solid lines refer to cultures seeded from parent cultures in stationary phase: the broken lines refer to cultures seeded from parent cultures in log growth phase. Each line represents the average of at least four experiments. Deoxyribonucleic acid was determined by the indole method (ref. 5), protein with phenol reagent (ref. 6) and cell number was counted in a hæmacytometer on aliquots of the undiluted medium

The results presented bring together some of the previous apparently conflicting data, and clearly support Salzman's contention[2] that deoxyribonucleic acid and protein content cannot be used indiscriminately as indications of cell number in tissue culture.

Stress Activation of Adrenal Glomerulosa

THE experimental data concerning the hormonal regulation of adrenal glomerulosa and its mineralocorticoid production[1] are still inconclusive. The demonstrated dependence of the glomerulosa reaction on the presence of pituitary[2] as well as on adrenocorticotrophic hormone[3] is contradictory to the absence of increased aldosterone secretion by adrenals perfused with either adrenocorticotrophic or somatistrophic hormone *in vitro*[4]. Nevertheless, it can be assumed that the former, and stress, activate the adrenal glomerulosa indirectly[5], mediated by the pituitary-dependent glucocorticoid production, which becomes properly balanced by means of mineralocorticoids[6]. This view will be supplemented by further experimental results.

Adult Wistar rats, males or females, divided into three separate groups (96 animals altogether), were subjected to stress by a single intra-muscular injection of 0·3 ml. 4 per cent formaldehyde/100 gm. body-weight. At intervals of 3, 6, 12, 24, and 48 hr. rats were killed. Frozen sections of adrenals were stained with sudan black *B* and with oil red *O* on lipids. The width of the zona glomerulosa was measured at a magnification of × 330, in all four quarters of the adrenal cortex. The number of leucocytes, eosinophils, and the differential count of leucocytes were also determined; the spleen and thymus were examined histologically.

In the unstressed rats of all three series the lipid content of the zona fasciculata was relatively low, resembling that of series *B*, described previously[5]. 3–6 hr. after the formaldehyde injection a considerable decrease and even disappearance of lipids took place in the fasciculata. The lipid content of the glomerulosa, however, remained unchanged. 24–48 hr. after the injection the lipids of fasciculata were gradually restored and simultaneously the glomerulosa was activated, as judged from the depletion of their lipids and from a statistically highly significant ($P<0.001$) enlargement (Fig. 2). The glomerulosa activation was associated with the transformation of light centres of spleen lymphatic nodules, previously activated by stress, into resting ones, and with the return of neutrophils to the initial level; that of lymphocytes ($P<0.01$) and eosinophils rose above the initial level (Fig. 1).

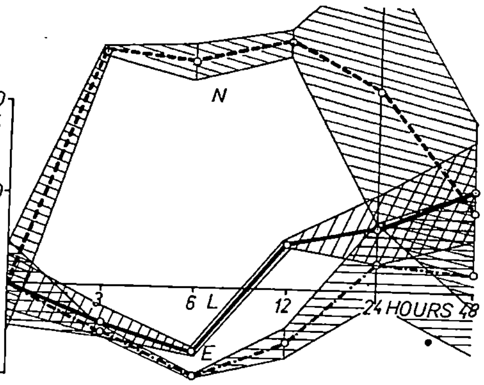

Fig. 1. The stress changes of neutrophils (*N*), lymphocytes (*L*) and eosinophils (*E*) expressed as a percentage of the mean initial value, with their standard deviations

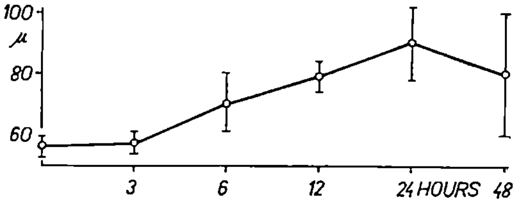

Fig. 2. The stress changes of the mean width of the zona glomerulosa in μ and their standard deviations

The findings show that the activation of the glomerulosa corresponds to changes in the leucocytes and the lymphoid tissue opposite to those found during the glucocorticoid phase of stress. Taking into account the mutual antagonism between mineralocorticoids and glucocorticoids[6], we may suppose that the activation of the glomerulosa is elicited by the antecedent glucocorticoid effects, especially their influence on electrolyte and water exchanges through the cell wall. Hence the stress reaction of the glomerulosa occurs as a balance to the glucocorticoid effects by abolishing them. The stress period can thus be divided into well-defined glucocorticoid and mineralocorticoid phases.

Electrical Response to Illumination of the Euphausiid Crustacean Eye

We have obtained reliably reproducible measurements of the electric potentials developed in the eyes of euphausiid crustaceans during stimulation by light. Such measurements may provide an objective method for the laboratory study of vision and photoregulated behaviour in planktonic forms which undergo vertical migrations too extensive to be duplicated experimentally with any available equipment. Preliminary observations of two species from the San Diego Trough off California, and one from Loch Fyne in Scotland, are presented here.

The specimens were collected with standard plankton nets and carried to the laboratory in refrigerated polythene or glass containers filled with off-shore water. Low temperatures (2–9° C.) and darkness improved their chance of survival, and, after an initial 24-hr. recovery period, any surviving animals lived for a week to ten days.

During an experiment an animal lay on its side in a groove across the surface of a lucite disk. Silver–silver chloride gauze on the bottom of the groove served as the indifferent electrode. The groove was narrow enough to restrict movement without interfering with respiration. The plastic disk rested in a Petri dish containing just enough sea water to cover the animal in the groove. The Petri dish was surrounded by an ice bath.

The recording electrode was a piece of tungsten wire etched electrochemically to a tip of less than 2-μ diameter, and insulated down to near this tip with 'Insulex'. (The electrode was dipped in a diluted solution of 'Insulex', clamped with tip upward and dried rapidly in a gentle downward air current.) This microelectrode was attached to a plastic rod held in a ball-and-socket joint, such that the tip might penetrate the eye without blocking the light. Glass micropipettes with silver–silver chloride electrodes were used at first, but penetration of the eye with the tungsten electrodes seemed to give less damage as judged by survival time and gave identical electrical responses. The preparation was housed in a light-tight, copper-shielded box.

The light source, a 12-volt concentrated tungsten filament lamp, was situated outside the box, as were the filter holder and shutter, so that colour, intensity and duration of the stimulating flash could be altered without disturbing the preparation. The light entered the box through a baffled collimating tube, struck a concave mirror set at 45° across the light path, and was directed downward on to the exposed eye. Interference filters were used in the colour determinations, and the dimensions of the collimator were such that the useful 5° cone of these filters was not exceeded. A heavy-duty storage battery supplied power for the lamp, and the voltage across the lamp terminals was monitored throughout the experiments. Light intensity was varied with neutral density filters.

The inner surfaces of the lamp housing, filter holder, collimator and light-tight box were painted matt black.

Electrical signals from the recording electrode were fed via a cathode follower to a resistance-coupled amplifier and an ink writer or a cathode-ray oscilloscope. Control experiments were run to make sure that no artefact occurred due to photochemical properties of the electrode system. No electrical signals were detectable when the recording electrode was illuminated at the highest experimental intensity, whether simply immersed in sea water or inserted in the eye of a dead animal. Furthermore, in the absence of light on the eye, no electrical activity could be detected even when the animal exerted swimming movements.

At the outset of an experiment the room was darkened, the stimulating lamp was turned on, the shutter was opened and a deep red filter was placed in the light path. The animal was transferred quickly from the dark storage vessel to the indifferent electrode. The position of the Petri dish was adjusted such that only the eye of the subject was illuminated, and the recording electrode was inserted. The shutter and the door of the light-tight box were then closed, and the animal remained in total darkness for at least 30 min. before measurements were begun.

The response to a brief flash (100 msec.) of 'white' light of moderate intensity is shown in Fig. 1, with representative curves from (*A*) *Euphausia pacifica*, (*B*) *Nematoscelis difficilis* and (*C*) *Meganyctiphanes norvegica*. The response in each species is rapid, with a small *a*-wave lasting about 20 msec., a main response which reaches a peak in 40–50 msec., and a final overshoot in the other direction. Over a defined range of intensities the height of the main response to short flashes of light varies directly with the logarithm of the intensity of the light. At very low intensities the signal is lost in the noise, and at high intensities the signal reaches a limiting value, of the order of 200–300 μvolts.

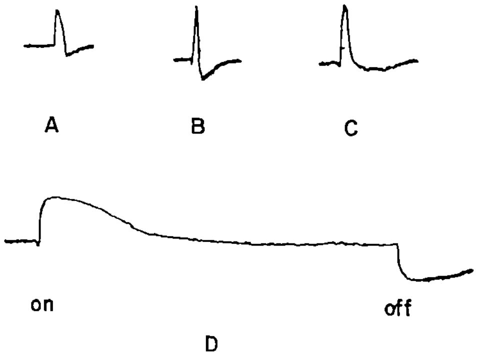

Fig. 1. Response to a 100-msec. flash of 'white' light by: (*A*) *Euphausia pacifica* (recorded with a cathode-ray oscilloscope); (*B*) *Nematoscelis difficilis* (recorded with a Beck–Lee ink writer); (*C*) *Meganyctiphanes norvegica* (recorded with an electro-encephalograph designed by Dr. Grey Walter); (*D*) response of *M. norvegica* to a 5-sec. flash

Light flashes of longer duration induce an electrical response at both on and off (Fig. 1 *D*).

Preliminary studies of response to light of various wave-lengths have been made, both for equal biological response and for equal energy of illumination. The euphausiid eye is most sensitive to blue-green light; but the spectral sensitivity curve does not coincide exactly with the spectral absorption curve of euphausiopsin, the light-sensitive pigment reported from the eyes of *Euphausia pacifica*[1].

The work on *E. pacifica* and *N. difficilis* was done at the Scripps Institution of Oceanography. The work on *M. norvegica* was done at The Laboratory, Plymouth. We should like to thank Dr. F. S. Russell, of Plymouth, and Dr. Harold Barnes, of Millport, for making the latter possible.

This work was carried out by the University of California under contract with the U.S. Office of Naval Research. Additional support was provided by National Science Foundation grant *G*–4801.

Melatonin in Peripheral Nerve

Melatonin is a hormone, isolated from beef pineal glands, that lightens the colour of frog melanocytes either after injection into the frog or after *in vitro* incubation with pieces of frog skin[1]. In addition, this hormone can block and reverse the darkening actions of the melanocyte-stimulating hormones and also of adrenocorticotrophic hormone. Melatonin is a 5-hydroxyindole derivative in which the hydroxy group is blocked[2]. Its melanocyte-lightening properties are more than ten thousand times greater than those of noradrenaline, which previously was considered to be the most potent lightening agent known[3]. In our early experiments melatonin could be detected only in extracts from pineal glands and not from other tissues. With improvement in extraction techniques we have been able to identify the presence of a lightening agent that is most likely melatonin in peripheral nerves of man, monkey and cow. A detailed mapping of the location of melatonin in the nervous system has not been completed.

Sciatic nerves from human beings were collected at autopsy and stored at −10° C. until a total of 65 gm. of tissue was obtained. This material was lyophilized to give 28 gm. of dry tissue. The latter was cut into small pieces and defatted with petroleum ether in a Soxhlet extractor. 10 gm. of dry, defatted nervous tissue was obtained which was pulverized to a powder in a Waring blendor. The powder was mixed with 100 ml. water in the blendor, and the mixture was centrifuged at 15,000*g* for 30 min. The supernatant fluid was filtered and the residue extracted with 100 ml. water and centrifuged again. The combined filtrates were extracted twice with equal volumes of ethyl acetate. The ethyl acetate layer was evaporated to dryness *in vacuo*. The residue was dissolved in a mixture of 10 ml. of each layer of solution used for counter-current distribution. This solvent system was made by equilibrating 2 parts of water with 1 part of ethylacetate and 1 part of *n*-heptane. All solvents were redistilled prior to use. The dissolved residue was subjected to 29 transfers in a counter-current distribution apparatus. The contents of the tubes were pooled into four groups: 0–7, 8–14, 15–22 and 23–29. From each pooled group the organic phase plus the upper phase obtained by re-extraction of the water layer with an equal volume of ethyl acetate were combined and evaporated to dryness *in vacuo*. The four residues, each dissolved in 2 ml. ethanol, were assayed for their ability to lighten isolated pieces of frog skin. Activity was found only in material from tubes 8–14. Similar results were obtained from extracts made in the same way using collections of sciatic, femoral and brachial nerves of monkeys and spinal nerve roots of cows. Purified melatonin, when subjected to a similar counter-current distribution, is found in greatest concentration in tube 11; and there is the expected decrease in concentration as one moves in either direction away from the peak tube. Tubes 8–14 contain nearly all the melatonin. The active material from tubes 8–14 of the counter-current distribution of human nerve was put through the counter-current machine again. Tube 11 contained the highest concentration of the lightening agent. This location coincides with that expected from distributing melatonin. There was not enough material in tubes 8–14 to test with Ehrlich's reagent or to obtain a fluorescence curve. Other known lightening agents, for example, noradrenaline, adrenaline, acetylcholine, serotonin, triiodothyronine and hydrocortisone, are eliminated by the extraction procedures.

Since the solubility and biological properties of the agent obtained from nerves of human beings, monkeys and cows are identical with those of melatonin and different from those of other known lightening agents, it is likely that the active principle is melatonin.

The function of this powerful melanocyte-lightening agent in peripheral nerve is not known. It may play a part in the transmission of nerve impulses and in the pathogenesis of vitiligo and malignant melanomas.

Effect of Enzymes on Mechanical Properties of Tissues

While investigating the effect of extending forces on the excised uterine cervix of the rat[1] we found that at the end of pregnancy the tissue showed prolonged extension at constant rate under low loads, behaving as if the collagenous framework in it was not continuous, as it is in the majority of tissues, but was one in which the ultimate links were viscous. In the course of investigating this viscous state we tried the effect of soaking the tissue in solutions containing trypsin. This was found to increase dramatically the rate of extension under constant load. Similar results were obtained from rings of skin cut from around the body-wall of newly born rats. Chymotrypsin was also tried on these and found to have the same effect as trypsin.

After excision, tissues were left overnight in the refrigerator (5° C.) in the enzyme solutions (crystalline Armour preparations, trypsin 0·5 mgm./ml., chymotrypsin 1·0 mgm./ml.) and incubated for 15 min. at 37° C. before testing. The method of using the enzymes and the concentration of trypsin were suggested to us by P. B. Medawar as suitable for detaching epidermis without killing the cells. Tissues were stretched between two parallel steel rods (stainless steel hypodermic needle tubing 0·6 mm. diam.). In the case of the cervix, one rod went through each canal, while the skin formed a belt around both rods.

Table 1. Rate of Linear Extension (percentage of l_0 per min.) under Constant Load

The number of animals is given in brackets. The estimate of variation is the standard error of the mean

	Normal	Trypsin-treated	Chymotrypsin-treated
Cervix (twenty-first day pregnancy) 50 gm. load	1·37 ± 0·33 (6)	30·7 ± 6·2 (3)	—
Skin (new born) 12 gm. load	0·038 ± 0·004 (6)	39·3 ± 10·2 (3)	4·7 ± 1·1 (3)

The tests were made in oxygenated Locke's solution, the tissues being loaded for periods up to 1 hr. and then broken by increasing the load in steps at constant intervals if they had not broken before.

Quantitative results are given in Table 1. The rate of extension under load is given as a percentage of the length at zero time (l_0) obtained by extrapolation backwards of the linear part of the curve (Fig. 1). Tension per unit cross sectional area of tissue calculated from weight of tissue for length l_0 was about 3 gm./mm.^{2} for both cervix and skin; per unit cross sectional area of collagen it was lower in the more collagenous cervix, that is, about 50 gm./mm.^{2} collagen as compared with about 200 gm./mm.^{2} collagen for skin.

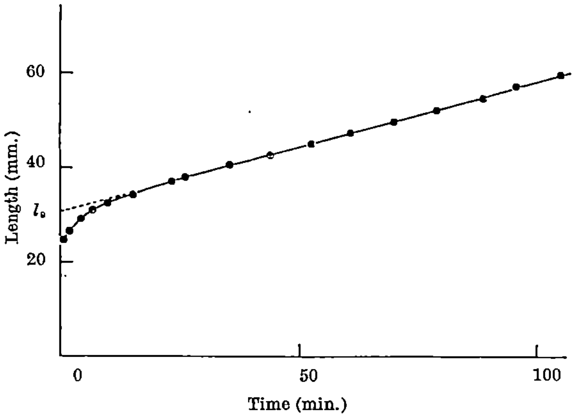

Fig. 1. Example of prolonged increase in length of tissue under constant load in cervix of rat at the end of pregnancy (twenty-first day). Length on the ordinate is that of the circumference of tissue around the rods. Load was 50 gm., giving a tension of approximately 3 gm./mm.^{2} at l_0

In contrast with the above results we have been unable so far to find any appreciable effect with hyaluronidase ('Hyalase', Benger).

Collagen itself is not attacked by trypsin or chymotrypsin, and these experiments appear to provide strong evidence that the collagenous framework is held together by some other unidentified protein on which the mechanical properties and integrity of the whole tissue depends. They strongly support the views put forward by Day[2] on the nature of the so-called 'cement substance' in connective tissue.

Hydrolysis of Lecithin and Lysolecithin by Rumen Micro-organisms of the Sheep

Although the diet of the ruminant contains only a small percentage of complex lipids (triglycerides, phospholipids, sterols, waxes), the actual amount ingested can be considerable because of the bulk of the food eaten. Furthermore the surface activity of such lipids may play an important physico-chemical part in ruminant digestion, and recent evidence suggests that the ingested chloroplast lipids act as efficient anti-foaming agents in the rumen[1]. At the present time, little is known about the way in which these complex lipids are digested by ruminants. Recently, however, Garton, Hobson and Lough[2] have described a rapid hydrolysis of triglycerides when these were incubated with sheep rumen contents.

The present communication describes observations made over the past two years on the hydrolysis of phospholipids by sheep rumen micro-organisms. When lecithin labelled with phosphorus-32[3] was incubated with sheep rumen contents, or a washed preparation of rumen micro-organisms there was a rapid breakdown of lecithin and the phosphorus-32 label appeared in the water-soluble fraction mainly as inorganic phosphorus. Similar incubations have been performed in the presence of a series of likely metabolic intermediates of lecithin hydrolysis, for example, phosphorylcholine, glycerylphosphorylcholine, glycerophosphoric acid, in order to trap the radioactive fragment split off from the lecithin and largely protect it from further catabolism. These substances were then separated from other phosphorus compounds in the incubation medium by two-dimensional paper chromatography and their radioactivity measured both by autoradiography and also by direct radioactive assay of the digested spots. Such experiments showed that the major catabolic pathway was via glycerylphosphorylcholine and glycerophosphoric acid. At the same time there appeared to be a minor pathway via phosphorylcholine.

Washed preparations of rumen micro-organsims also hydrolysed lysolecithin, although individual animals showed wide variations in the level of activity. By autolysis of the micro-organisms or on their treatment with butanol a soluble preparation of the enzyme was obtained. This has been purified by ammonium sulphate precipitation and adsorption on calcium phosphate gel. Such preparations possess no lecithinase activity but they readily hydrolyse lysolecithin producing glycerylphosphorylcholine. Lysophosphatidyl ethanolamine is also attacked. The *p*H optimum in collidine–hydrochloric acid buffer is 7·5, which is different from the *p*H optima of the lysolecithinases of animal tissues (6·0) and moulds (3·3–4·0). In buffers containing alkali metals, for example sodium glycine–glycine, the activity was much greater at high *p*H's (7·5–9·5) than in buffers with organic bases. The enzyme does not appear to need any metal ion for activation, and it is not appreciably affected by ethylenediamine tetraacetic acid. It is comparatively insensitive to inhibition although copper and zinc ions are effective, as is also 0·01 per cent cetyltrimethylammonium bromide.

No information has been obtained as to the identity of the organism(s) responsible for the phospholipid hydrolysis. Cultures of mixed rumen streptococc grown in a glucose rumen–liquor medium possessed little lysolecithinase activity. Hayaishi and Kornberg have reported that a soil bacterium *Serratia plymuthicum* can metabolize lecithin via glycerylphos phorylcholine while the hydrolysis of lecithin to phosphorylcholine (lecithinase *C*) by some members of the *Clostridium* genus is well known[5,6]. Recently, *Bacillus cereus* has also been shown to contain a lecithinase *C*[7].

The level of lysolecithinase in the rumen micro-organisms seems to be dependent upon the diet of the animal. Nevertheless the presence of phospholipid in the food did not appear to be essential, as an animal receiving a synthetic diet of cellulose and mineral salts with a minimum hay supplement (15 per cent) still retained considerable lysolecithinase in its rumen micro-organisms. It is interesting, however, that in these circumstances the enzyme was no longer solubilized by autolysis of the micro-organisms although butanol treatment was effective.

Bilirubin Metabolism in the Fœtus

It has been shown that in fœtal liver the enzymatic mechanism for glucuronide formation is poorly developed, while a rapid increase in enzymatic activity occurs during the early neonatal period[1]. The transient hyperbilirubinæmia observed during the first few days of life is believed to be related to this inadequate development of the hepatic conjugating system[1]. Since a significant increase in serum bilirubin concentration usually occurs only after the cord is severed, it has been assumed that during gestation the placenta is responsible for the removal of fœtal bilirubin. It has not been determined, however, whether the placenta has the ability to conjugate the fœtal pigment or whether placental transfer of unconjugated bilirubin occurs from the fœtal to the maternal circulation.

In vitro, glucuronide formation was studied[2] both with human placenta obtained at term or by Caesarean section and with rat placenta at various stages of gestation. Incubations were carried out with tissue slices, homogenates and microsomal preparations in the presence of UDPGA, using as substrates bilirubin, *o*-aminophenol and *p*-nitrophenol[2]. In these systems, no evidence for glucuronide formation was obtained. Moreover, supravital perfusion of human placenta[3] failed to reveal formation of bilirubin glucuronide.

In view of these negative results, placental transfer of bilirubin was studied in pregnant guinea pigs during the last week of gestation using a modification of the method described by Dancis *et al.*[4]. On the maternal side, a uterine vein was cannulated which permitted continuous sampling of venous blood from an individual placenta. The corresponding fœtus was delivered into a saline bath, maintained at 37° C., and an umbilical artery was cannulated, while the umbilical vein was severed and the cord clamped proximal to the fœtus. Over a period of 1 min., 0·4 mgm. crystalline bilirubin, dissolved in 1 ml. of either 5 per cent human albumin or guinea pig plasma, was infused through the cannulated umbilical artery. In addition, the injected solution contained either iodinated human albumin (2,500,000 counts/min./ml.) or chromated guinea pig erythrocytes (3,000,000 counts/min./ml.). Blood samples from the uterine vein were taken before, during and at various time-intervals after the injection for estimation and paper chromatography[5] of bilirubin and for determination of the radioactivity in albumin and in erythrocytes.

The injected bilirubin was rapidly transferred through the placenta and was present in the maternal blood as non-conjugated bilirubin. Peak concentrations ranging from 0·6 to 2·0 mgm. per cent were reached in the uterine venous blood 2–4 min. after the beginning of the injection. As seen in Fig. 1, iodinated albumin was transferred at a rate similar to that of bilirubin. On the other hand, no radioactivity was detected in the maternal blood if bilirubin was injected together with chromated erythrocytes. Similarly, injection of crystalline bilirubin into the maternal circulation resulted in its rapid appearance in the fœtal blood. Conversely, if bilirubin glucuronide obtained from human bile and iodinated albumin were injected into the umbilical artery, transfer of conjugated bilirubin was minimal, while radioactive albumin rapidly appeared in the maternal blood.

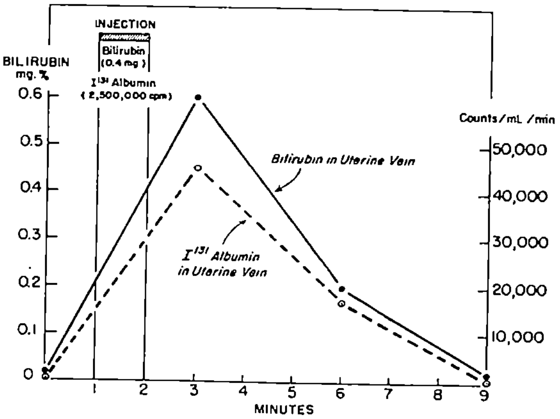

Fig. 1. In a pregnant guinea pig shortly before term, 0·4 mgm. bilirubin and albumin labelled with iodine-131 (2,500,000 c.p.m.) were injected into a fœtal umbilical artery. Concentrations of bilirubin and radioactive albumin were determined in the corresponding uterine vein

These observations indicate that under the experimental conditions employed, non-conjugated bilirubin was rapidly transferred from the fœtal to the maternal circulation, while transfer of conjugated bilirubin was insignificant. They are in agreement with the findings of Dancis *et al.*[4] that œstrogens but probably not œstrogen glucuronides can pass the placental barrier. In view of these findings, the possibility was considered that the inadequate development of the mechanism for glucuronide formation in the fœtal liver may be due to a lack of substrate during the intra-uterine period. This problem was studied by injecting six pregnant rats with large amounts of anthranilic acid, a compound which is largely excreted as an acyl-glucuronide[6]. During the last six days of gestation, 50 mgm. sodium anthranilate/100 gm. body-weight were injected twice a day by intraperitoneal route and a

Table 1. EFFECT OF INJECTION OF SODIUM ANTHRANILATE ON THE BIOSYNTHESIS OF *o*-AMINOPHENYL GLUCURONIDE BY MICROSOMES OF MATERNAL AND FŒTAL RAT LIVERS *in vitro*

Type of treatment and No. of animals	*o*-Aminophenyl glucuronide formed	
	Mother	Fœtus
Saline (control), 6	0·044 ± 0·013	0·008 ± 0·005
Anthranilate, 6	0·041 ± 0·019	0·011 ± 0·003

Washed microsomes obtained from 1 gm. of liver were incubated for 30 min. at 37° C. with 0·2 μmole *o*-aminophenol, 1 μmole UDPGA and 25 μmoles magnesium chloride in 0·1 *M tris* (hydroxymethyl) amino-methane buffer, *p*H 8·0. Results are expressed as μmoles formed per gram of liver ± standard deviation

similar group of pregnant rats was given a comparable amount of saline. 12 hr. after the last injection, the animals were decapitated, and microsomes were prepared from the fœtal and maternal livers. In mothers treated with anthranilate, fœtal liver exhibited anthranilic acid concentrations[7] of 18·3 μgm. (*S.D.* 5·9 μgm.) per gm. tissue, while none was detectable in maternal livers or in fœtal livers of saline-treated mothers. Washed microsomes obtained from 1 gm. of liver were incubated with *o*-aminophenol and UDPGA and the amount of *o*-aminophenyl glucuronide formed was estimated[2]. As seen in Table 1, no difference in glucuronide formation was observed between microsomal preparations of fœtal livers that were obtained from mothers treated with anthranilate or with saline. Moreover, the magnitude of glucuronide formation by microsomes of maternal livers was similar in both groups of rats. Per gm. of liver, fœtal microsomes exhibited about four times less enzymatic activity than maternal preparations; but if the values were expressed per mgm. of microsomal protein nitrogen, this difference was much smaller. This is believed to indicate that on a weight basis fœtal liver may contain less precipitable microsomal particles than adult liver.

The results suggest that in fœtal rat liver increased activity of the glucuronide-forming enzyme system cannot be induced by the presence of substrate, even though the aglycone is present in considerable concentration over the last five days of gestation. Other factors must be responsible for the 'immaturity' of the fœtal liver. To what extent these observations may be applicable to man remains to be elucidated.

These studies were supported by United States Public Health Service Research Grants No. *A*-1833 (*C*) and No. *R.G.*-5333.

Flavone Glucosiduronic Acids in *Scutellaria* sp.: a Correction

IN the course of studies on the isolation of flavone glucosiduronic acids from various skull-caps, specimens of a localized colony at Mells, Somerset, which had been identified as *Scutellaria columnae* Tenore[1], were reported[2] to contain scutellarin (5,6,7,4′-tetrahydroxyflavone β-glucosiduronic acid) and not baicalin (5,6,7-trihydroxyflavone β-glucosiduronic acid) as found previously[3] in this species grown in the area of Paris. This anomaly is now removed by the recent re-identification[4] of the Mells skull-cap as *Scutellaria altissima* L., a native of south-east Europe. Scutellarin was originally isolated from this plant[5].

Thanks are due to Dr. A. J. Willis for directing my attention to this reclassification.

Relationship between Auxins and Nucleic Acid Synthesis in Coleoptile Tissues

THAT auxins may affect nucleic acid metabolism in plants has been suggested by a number of workers. Silberger and Skoog[1] had observed an increase in both the deoxyribonucleic acid and ribonucleic acid content of tobacco pith cells incubated with 0·01 to 10 mgm./l. of indole acetic acid. Growth continued in a manner somewhat similar to changes in the ribonucleic acid content for a few days even though the synthesis of nucleic acids had apparently stopped after four days of application of indole acetic acid. Holmes *et al.*[2] have shown that in *Vicia* root, as the distance from the root tip increased the content of deoxyribonucleic acid per cell also increased. Attempts have been made to correlate root growth with nucleic acid metabolism in other plants as well[3-5]. In maize roots it has been found that application of indole acetic acid resulted in a slowing down of growth accompanied by a decrease of both deoxyribonucleic acid and ribonucleic acid[3]. Some workers are inclined to believe that growth and synthesis of deoxyribonucleic acid in plants continues only in the presence of auxins[6-8]. The present communication summarizes the results obtained in an investigation on the incorporation of compounds labelled with phosphorus-32 and carbon-14 into the coleoptile tissues as affected by indole acetic acid.

Seeds of *Avena sativa* var. *N.P.*1 and *Oryza sativa* var. Rupsail were used. The seeds were germinated in the dark with occasional red light for 3 days. The coleoptiles were then decapitated at 2–3 mm. and floated on water for 2 hr. to free them from any endogenous auxin. After a further decapitation by another 2–3 mm., 5-mm. sections were cut off and floated on the experimental solution containing $Na_2H^{32}PO_4$ (50 μc./ml.) of specific activity greater than 1 mc./μgm. phosphorus in *M*/150 phosphate buffer of *p*H 6·0 for 2 hr. with or without indole acetic acid. For rice, 5-day old coleoptiles were used. ($Na_2H^{32}PO_4$ was obtained from N.V. Philips Roxane

Table 1. THE EFFECT OF INDOLE ACETIC ACID ON INCORPORATION OF PHOSPHORUS-32 IN THE NUCLEIC ACIDS OF RICE (VAR. RUPSAIL) COLEOPTILES

Results expressed as counts/min. in the nucleic acid per mgm. of coleoptile × 10^{-3}

Treatment	Ribonucleic acid	Deoxyribonucleic acid
Control	426·6	296·5
10^{-6} *M* indole acetic acid	632·6	387·4

Pharm.-Chem. Industrie Netherlands.) After the end of the incubation period, cold trichloracetic acid was added and the nucleic acids fractionated according to the method of Ogur and Rosen[9]. Measurements of radioactivity were taken with a Nuclear Chicago halogen counter coupled with a Tracerlab autoscaler.

The results are presented graphically in Fig. 1. With low concentration of indole acetic acid there is a marked stimulation of incorporation of phosphorus-32 into both deoxyribonucleic and ribonucleic acid fractions. In the latter, a concentration of 10^{-9} *M* indole acetic acid has practically no effect; but 10^{-6} *M* has a distinct stimulatory effect, the increase observed being more than 50 per cent. In the former, the rate of incorporation of phosphorus-32 is much slower, and the maximum increase observed due to the application of indole acetic acid was 20 per cent. With 10^{-3} *M* indole acetic acid there appears to be an inhibition in the incorporation of phosphorus into deoxyribonucleic acid. Similar stimulation of incorporation of phosphorus-32 due to low concentrations of indole acetic acid was also observed when rice coleoptiles were incubated with 125 μc./ml. of $Na_2H^{32}PO_4$ in phosphate buffer with and without 10^{-6} *M* indole acetic acid.

To study the utilization of compounds labelled with carbon-14 for nucleic acid synthesis the coleoptiles were incubated with the following compounds (obtained from the Radiochemical Centre, Amersham, Great Britain) in *M*/165 phosphate buffer of *p*H 7·0 with or without 10^{-6} *M* indole acetic acid: (1) sodium acetate-1-^{14}C (37 μgm./μc.)—45 μc./ml.; (2) acetate-2-^{14}C (14·9 μgm./μc.)—9 μc./ml.; (3) $NaH^{14}CO_3$ (3·7 μgm./μc.)—45 μc./ml.; (4) sodium formate-^{14}C (14·1 μgm./μc.)—45 μc./ml.; (5) glycine-1-^{14}C (22 μgm./μc.)—10 μc./ml. When the nucleic acids were extracted and isolated as described above no stimulation of incorporation of carbon-14 was observed in both ribonucleic and deoxyribonucleic acids, with the exception of glycine.

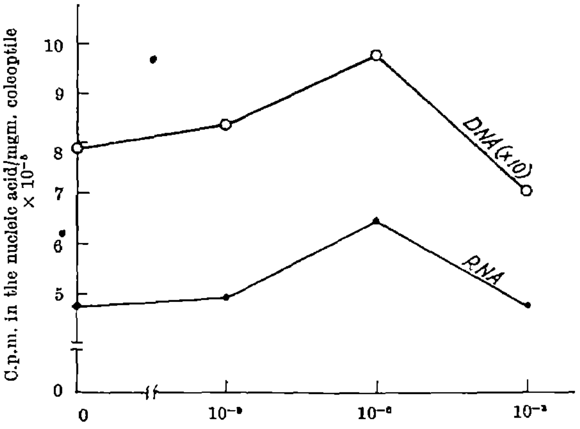

Fig. 1. Effect of indole acetic acid on the incorporation of phosphorus-32 into the nucleic acids of *Avena* coleoptile. The values for deoxyribonucleic acid have been multiplied by 10 for clarity

It thus appears that the effect of auxins on nucleic acid synthesis during the first 2 hr. of application is exercised through its effects on the synthesis of nucleotides composing the nucleic acids. That indole acetic acid stimulates the synthesis of nucleotides and phosphorylation reactions has now been confirmed with compounds[10] labelled with phosphorus-32, as also through the recent work of Marre[11]. The compounds labelled with carbon-14 used are all known to contribute to the synthesis of purine and pyrimidine bases of the nucleic acids. Apparently during the first 2 hr. of application of indole acetic acid the reactions leading to their synthesis or of the sugar moieties of the nucleic acids are not much affected, even though the phosphorylation reactions are.

BACTERIOLOGY

Neutralization of Bacteriophage by Normal Serum

NORMAL mammalian serum of most species is capable of neutralizing bacteriophages of the *Escherichia coli T* series. This activity of normal serum has been attributed to the properdin system although a lack of correlation between properdin-levels and phage-neutralizing activity was noted with certain sera[1]. Recent work by Cowan[2], moreover, in which several human sera were assayed for activity against *T*2, *T*6, and *T*7, indicated that the phage-neutralizing activity of a serum against one of the phage types was not correlated with its activity against the other two. These results suggested that the properdin system, essentially non-specific in its action, could not adequately account for the activity of normal serum against the three phage types. Cowan postulated, therefore, that properdin might be a family of cross-reacting antibodies capable of combining with zymosan. Similar considerations are applicable to other activities of normal serum. Our own findings in studies of the bactericidal action of normal serum against several species of Enterobacteriaceae indicated that bactericidal antibody of marked specificity plays the major part[3].

A more direct demonstration of the significance of normal antibody of marked specificity, as opposed to properdin, in the phage-neutralizing activity of normal serum was obtained in our laboratory.

Escherichia coli bacteriophage $T2$ was prepared and concentrated as described by Herriot and Barlow[4]. High-titred cultures of phage $T5$ were obtained by using the procedure outlined by Adams[5]. Phage-*E. coli* complexes were prepared by the addition of bacteriophage concentrates $T2$ or high-titred broth cultures $T5$ to 100 ml. aliquots of tryptone broth cultures of *E. coli* B (at least 3 days old) at 37° C. The cultures then contained approximately 25 infective phage particles per bacterium. After 1–2 min., formalin was added to inactivate both phage and bacteria. After 3 hr. at room temperature, the bacteria with attached phage were centrifuged in the cold. When $T2$ was used, the bacteria formed a highly viscous residue which was washed twice with saline. This viscosity was due to the deoxyribonucleic acid in the residue. Digestion of this acid was accomplished by the addition of 10 ml. of 0·15 *M* sodium chloride solution, 0·1 ml. of 0·028 *M* magnesium sulphate solution and 10 μgm. of deoxyribonuclease (Worthington Biochemical Corp.). The enzyme was allowed to act overnight at room temperature. This treatment was sufficient to allow resuspension of the bacteria with attached phage, which were sedimented by centrifugation prior to the addition of serum. With $T5$, the bacteria formed a residue easily resuspended in saline. Digestion with deoxyribonuclease was therefore not required. The *E. coli*-$T5$ complex was washed three times with saline prior to the addition of serum. As a control, *E. coli* cells without phage were similarly treated with formalin and saline. Each serum (10 ml.) was adsorbed twice with either the *E. coli*-$T2$ or *E. coli*-$T5$ preparations for 1 hr. at 0° C. An aliquot was similarly treated with the control *E. coli* cells.

Phage-neutralizing activity titres of adsorbed and unadsorbed sera using homologous and heterologous bacteriophage are summarized in Table 1. Adsorption of normal serum with *E. coli*-phage complex resulted in almost complete removal of phage-neutralizing activity when tested against the homologous phage. In contrast, when this adsorbed serum was titrated against heterologous phages in the T-series, phage-neutralizing activity was essentially equal to that of the unadsorbed serum. This indicates that the component essential for the neutralization of phage by normal serum is a substance characterized by marked specificity. It is also interesting to note that the serum adsorbed with $T2$ phage and titrated against $T4$ and $T6$, both serologically related to $T2$ [6], had about 50 per cent of the phage-neutralizing activity of the untreated serum. Conversely, the same serum, when tested against serologically unrelated phage, showed only slight diminution of activity as compared with the neutralization by the untreated serum.

Table 1. NEUTRALIZATION OF HOMOLOGOUS AND HETEROLOGOUS BACTERIOPHAGE BY ADSORBED AND UNADSORBED NORMAL HUMAN SERUM

Serum No.	Phage-neutralizing activity titre* against: $T2$	$T4$	$T6$	$T5$	$T7$
120858 Untreated	23	7	65	10	16
120858 Adsorbed with *E. coli*-$T2$	<1	3·3	37	9·5	15
20959 Untreated	22	11	51	16	25
20959 Adsorbed with *E. coli*-$T5$	19	6	46	<1	23

* The reciprocal of the amount of serum (ml.) required to neutralize 50 per cent of about 10^3 phage particles in a total volume of 1 ml. at 37° C. for 1 hr. Serum and phage were diluted in veronal buffer containing 0·1 per cent bovine serum albumin (ref. 2).

Table 2. COMPLEMENT, PROPERDIN AND PHAGE-NEUTRALIZATION (PNA) TITRES OF UNADSORBED AND ADSORBED NORMAL HUMAN SERUM

Human sera	Serum No. 120858			Serum No. 20959		
	PNA titre against $T2$	Complement units*	Properdin units†	PNA titre against $T5$	Complement units*	Properdin units†
Untreated	23	240	12	16	230	12
Adsorbed with *E. coli* cells	19	216	4	14	230	6
Adsorbed with homologous *E. coli*-T phage complex	<1	180	4	<1	192	6

* The reciprocal of the dilution of serum required to hæmolyse 50 per cent of the sensitized sheep erythrocytes ($1 \cdot 5 \times 10^8$ cells) in a total volume of 1·5 ml. at 37° C. for 30 min. Triethanolamine buffered saline was used as diluent.

† Euglobulin precipitates dissolved in endpiece were assayed as described (ref. 8).

Studies of the adsorbed and unadsorbed sera were undertaken to characterize further the serum components responsible for this activity against phage. Since the properdin system has been suggested as the factor in normal serum required for phage neutralization[7], it was necessary to measure the complement- and properdin-levels in adsorbed and unadsorbed sera. The complement titres in Table 2 indicate a slight loss in hæmolytic complement as a result of the adsorption. The slight reduction in phage-neutralizing activity against heterologous phage types seen in Table 1 may be related to this complement loss. From the properdin and phage-neutralizing activity titres in Table 2, it can be seen that adsorption with *E. coli* cells alone resulted in a 2–3 fold reduction in properdin with a scarcely detectable decline in phage-neutralizing activity. The results in Table 2 also indicate that the attached phage particles are not responsible for any detectable loss of properdin. Of greater significance, however, the phage-neutralizing activity is markedly reduced in the serum adsorbed with homologous phage despite the presence of the properdin system components. Only very slight reduction in activity occurred in the serum adsorbed with *E. coli* cells alone. Yet the properdin-levels in both adsorbed sera were the same and were within normal limits. The results indicated that sera adsorbed with homologous phage but having components of the properdin system were incapable of phage neutralization. Normal antibody, removed by adsorption with the homologous phage, appeared indispensable.

The origin of normal antibodies to phage, or to any microbe, is not readily determined. That some normal antibodies are specific does not necessarily favour any particular theory concerning their origin. It merely means that they react with certain organisms, and not with others, because of a chemical correspondence of certain specific combining groups. The pooled sera of 6 germ-free 6-week-old guinea pigs possessed greater phage-neutralizing activity against $T2$ (titre equal to 33) than the sera of conventional guinea pigs (titre equal to 18) of the same strain and age. Hæmolytic complement- and properdin-levels of the two pools did not differ. Of course, germ-free animals are not necessarily free from viruses and are subjected to a variety of antigenic materials from sterile foods and viruses which may possess antigenic groupings cross-reactive with those of the T-phages. Thus, the possibility that phage-neutralizing activity resulted from antigenic stimulation in these germ-free animals cannot be excluded. The globulin-levels of the germ-free animals tested were considerably below normal, however, and the gamma fraction was scarcely detectable by paper electrophoresis.

Properdin has been described as a single substance capable of neutralizing viruses and destroying certain abnormal red cells and bacteria[9]. The results of our experiments indicate that normal antibodies of marked specificity, rather than properdin or other non-specific substances, are essential requirements for phage-neutralizing activity. In the presence of antibody, properdin may conceivably augment the existing phage-neutralizing activity.

An experiment by Bordet[10] in 1899 led to a similar conclusion. The question was raised at that time whether the activities of normal serum could be explained by one substance, or a few substances. Bordet adsorbed normal horse serum with cholera vibrios, and after removal of the cholera vibrios with attached agglutinins by centrifugation the serum lost its ability to agglutinate cholera vibrios but clumped typhoid bacilli as intensely as the unadsorbed serum.

We wish to thank Drs. M. Forbes and S. Formal for the germ-free animal sera obtained from the Germ-free Research Project, Walter Reed Army Institute of Research. We also wish to thank Mr. W. Spilman of the Division of Immunology, Walter Reed Army Institute of Research, for his suggestions in the preparation of concentrated $T2$ phage suspensions.

Spermine as a Protective Agent against Osmotic Lysis

Previous studies have revealed a close relationship between the growth requirement of *Pasteurella tularensis* and *Neisseria perflava* for spermine or allied polyamines and their marked osmotic fragility[1,2]. The susceptibility of those bacteria to the osmotic environment is manifested by leakage of cell material, rapid decay of respiratory ability and a sharp decline of viability following their brief exposure to distilled water. In the case of *P. tularensis* the osmotic cell damage is largely prevented by microgram amounts of spermine. On the other hand, the dependence of *N. perflava* on spermine as an essential growth factor in a chemically defined medium can be eliminated by proper adjustment of its tonicity.

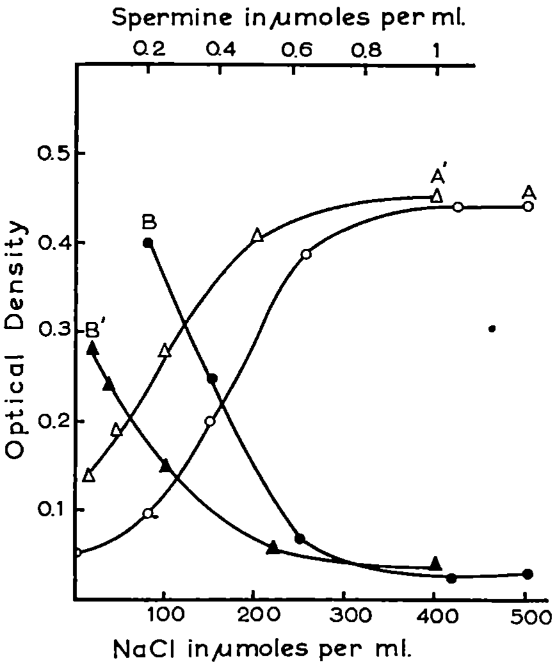

Fig. 1. Comparison of the protective effect of sodium chloride and spermine against osmotic lysis of *Achromobacter fischeri*. Washed cells of *A. fischeri* (about 3 mgm. protein content) were suspended in 1-ml. amounts of a 3 per cent sodium chloride solution supplemented with spermine in amounts corresponding to those indicated in the figure. At the end of 15 min. incubation the cells were spun off and resuspended in 5-ml. samples of the various sodium chloride or spermine solutions tested. After additional 30 min. incubation the extent of lysis was determined by measuring the turbidity of the suspensions and the absorbance of the supernates following centrifugation. Incubation temperature, 28° C. Curves *A*, *A'* and *B*, *B'* represent turbidity of the suspensions at 550 mµ and absorbance of the supernates at 260 mµ in the various sodium chloride and spermine solutions respectively (see text)

The present communication reports on the ability of spermine to prevent osmotic lysis in the obligate halophilic species, *Achromobacter fischeri* (A.T.C.C. 7744).

This organism is perfectly stable when suspended in the standard 0·5 M sodium chloride solution. It starts disintegrating, however, as soon as the osmotic strength of the suspending medium is diminished down to a critical level of about 0·25 M sodium chloride, below which the extent of cytolysis progresses in a roughly proportional manner to the decrease of osmolarity (Fig. 1). The cell rupture is evidenced by a drop in the turbidity of the suspension (curve *A*), as well as a concomitant increment in the absorbance of the cell-free supernate following centrifugation (curve *B*). The rise in optical density of the supernate is obviously attributable to leakage of cell constituents and the strong maximum exhibited close to 260 mµ is indicative of a large share of nucleotidic material.

The drastic lysis of *A. fischeri* which occurs in distilled water could be completely suppressed by adding 0·0005 M spermine provided that the cells have been pre-incubated with a similar amount of spermine while suspended in the standard sodium chloride solution. Graded amounts of spermine afforded, within a certain range of mounting concentrations, increasing protection against osmotic lysis, a definite effect being still perceptible with a quantity as low as 5 µgm./ml. (curves *A'*, *B'*). Putrescine and spermidine, known biosynthetic precursors of spermine[3], when tested under similar conditions, proved to be practically inert in the present system.

Attempts to grow *A. fischeri* in a 1 per cent peptone medium (freed by 'Norit *A*' treatment of its spermine content) devoid of sodium chloride but supplemented with spermine, were unsuccessful. Preliminary experiments, however, indicate that spermine exerts a definite growth furthering effect in combination with osmotically inadequate concentrations of sodium chloride (0·5 per cent).

The mechanism whereby spermine in these relatively minute amounts imitates the osmotic effects of salts is now being explored. A possible interplay with nucleic acids is suggested by the pronounced cationic characteristics of the compound and also by some reported interactions of apparent biological significance[4,5]. It may be concluded, therefore, that the present observations appear to bear out in a rather striking fashion the previously postulated role of spermine as a factor influencing cellular permeability[1,2]. Furthermore, some preliminary findings with a number of additional organisms suggest that the 'osmomimetic' function of this rather ubiquitous polyamine[6] may be of much wider applicability than hitherto anticipated.

Phagocytosis of *Escherichia coli* Protoplasts

This communication reports the results of experiments on phagocytosis of the bacterial protoplasts prepared from *Escherichia coli* B, and on phagocytosis of bacterial vegetative forms obtained from these protoplasts by reversion.

The protoplasts were prepared by Lederberg's penicillin method[1]. Before each experiment the protoplasts were washed free of saccharose with physiological saline.

Both protoplasts and vegetative forms of *E. coli* were used for phagocytic tests made with horse leucocytes. The phagocytic reactions were carried out in various media, namely, in fresh undiluted serum, in fresh diluted (1 : 10) serum, in undiluted serum inactivated for half an hour at 56° C., and in inactivated diluted serum (1 : 10). The phagocytic indices were thus determined, both in the presence and in the absence of thermolabile components of complement. Such experiments afford an opportunity for discovering possible differences in the degree of phagocytosis of normal vegetative forms and of protoplasts, depending on the presence or absence of complement and fresh serum. The diluting of serum was necessary to avoid inhibition of the degree of phagocytosis. Such inhibition occurs in the phagocytic reaction with *E. coli*.

The phagocytic indices were determined by the method of Skurski *et al.*[2] without prior sensitization; the time of phagocytosis was 20 min. Comparison of the phagocytic indices afforded a measure of the phagocytosis of both vegetative forms and protoplasts. According to Wright's definition[3], the phagocytic index is the average number of bacterial cells phagocytized by one leucocyte (100 leucocytes were counted in each preparation).

The results are presented in Table 1. They show the existence of large differences in the degree of phagocytosis, the phagocytic indices obtained with protoplasts being significantly lower than those obtained with mother cells. Photomicrographs showed that protoplasts within leucocytes (phagocytized protoplasts) were swollen, whereas the shape of protoplasts outside the leucocytes were similar to those in control preparations.

Table 1. Phagocytosis of Protoplasts and Normal Forms of *E. coli* B, and of *E. coli* B Cells obtained by Reversion of Protoplasts

Phagocytized cells	Phagocytic indices			
	Normal serum		Inactivated serum	
	Undiluted	Diluted 1 : 10	Undiluted	Diluted 1 : 10
E. coli B (normal forms)	12·0	19·3	23·2	13·9
Protoplasts	1·9	5·0	9·5	4·7
Protoplasts after 6 hr. incubation	11·0	22·0	24·4	10·0
Protoplasts after 24 hr. incubation	10·0	19·0	23·3	9·5

Lederberg[1] reports that in favourable conditions reversion of protoplasts to the mother forms may occur. We have investigated this phenomenon in relation to phagocytosis. Reversion occurred in broth at 37° C. It is evident from Table 1 that after 6 hr. incubation of the protoplasts at 37° C. in broth, the phagocytic indices returned to the values obtained in control tests with mother cells. The differences in the values of the phagocytic indices of vegetative forms and of protoplasts were independent of the medium in which the phagocytic reaction occurred.

The protoplasts were much less readily phagocytized both in the presence of fresh serum (containing all the active components of complement), and in inactivated serum (containing inactivated thermolabile components of complement).

According to Park and Strominger[4], penicillin inhibits the biosynthesis of bacterial cell walls giving the protoplasts. The present communication indicates that the removal of cell walls leads to significant inhibition of the phagocytic reaction.

Prolongation of incubation times up to 24 hr. failed to change the phagocytic indices. Typical vegetative forms were observed after incubation for 24 hr., whereas after 6 hr. incubation both vegetative forms and protoplasts appear. Neither reversion nor phagocytic indices changes were observed with protoplasts stored at 2° C. in physiological saline and 20 per cent saccharose for several days.

This investigation is being continued, and the details will be published elsewhere.

Production of Bacterial Mutants with Nitrous Acid

Recently, Mundry and Gierer[1] used nitrous acid to produce mutants of tobacco mosaic virus by chemical alteration of its ribonucleic acid, as demonstrated by Schuster and Schramm[2]. This communication deals with the mutagenic effects of nitrous acid on living cells of the bacterial species *Escherichia coli* and *Salmonella typhimurium*, the genetic substance of which is deoxyribonucleic acid.

Nitrous acid inactivates bacterial cells, reducing the ability of a suspension to form colonies. In the experiments described here, the rate of inactivation varied with differences in the state of metabolism of the cells. Those with active metabolism gave higher rates of inactivation per unit time than cells which were in a resting phase. The inactivation of such resting cells, which have only one nucleus, followed a double-hit curve (Fig. 1). Starting with about 10^8 cells per ml. its slope was tested for four logarithmic cycles of the ordinate.

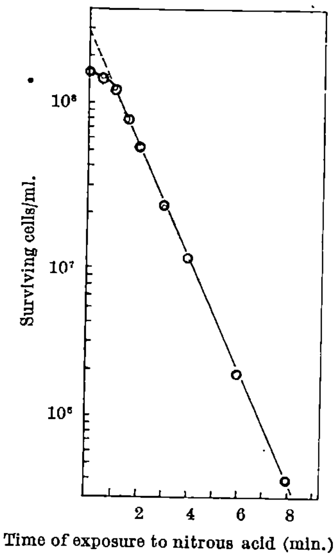

Fig. 1. Sensitivity of resting cells of *E. coli*, strain *B*, to 0·017 *M* nitrous acid (*p*H 4·5)

Wild-type cells of *E. coli*, strain *B*, which had survived treatment with nitrous acid, were plated on nutrient agar so as to give about 150 colonies per plate. Their synthetic abilities were tested by replica-plating[3] the colonies on minimal medium. Since this medium contained only glucose and inorganic salts, it supported growth of the wild-type strain but inhibited the multiplication of cells which had mutated to auxotrophy. Using this technique, auxotrophic mutants induced by treatment with nitrous acid were found. By means of a method published elsewhere[4] the mutants were tested for their growth requirements.

Details of the experiments and conclusions drawn are as follows.

(1) Nitrous acid is a potent mutagen: with an inactivation-rate of 10^{-5} about 4 per cent of surviving cells were auxotrophic mutants.

(2) The spectrum of mutants (Table 1) induced by nitrous acid differs significantly in some respects from that observed after induction with ultraviolet, other mutagens or after spontaneous origin. It is identical with the spectrum of mutants found after induction by disintegration of incorporated phosphorus-32 [4]. The most striking features are the very rare occurrence of mutants blocked in the synthesis of glycine, glycine or serine and cysteine; and the rather high frequency of purine- and pyrimidine-less mutants mainly of the cytosine- or uracil-less type as well as of the argine-less type.

Table 1. Distribution Pattern of Nutritional Requirements found in Auxotrophic Mutants induced by Incubation of Wild-Type Cells of *E. coli*, Strain *B*, with Nitrous Acid

Nutritional requirements tested	No. of mutants found	Nutritional requirements tested	No. of mutants found
Adenine	21	Proline	11
Adenine or guanine	2	Proline or glutamic acid	1
Guanine	4	Serine	2
Cytosine	0	Threonine	9
Cytosine or uracil	17	Tryptophane	28
Thymine	2	Tyrosine	9
Arginine	55	Valine	17
Aspartic acid	2	Ascorbic acid	0
Cysteine	30	Nicotinic acid	13
Cysteine or methionine	10	Pantothenate	0
Glutamic acid	3	Pyridoxal-phosphate	2
Glycine	4	Pyridoxal-phosphate or glutamic acid	1
Glycine or serine	2	Riboflavin	0
Histidine	37	Riboflavin or nicotinic acid amide	3
*iso*Leucine	9	Other unanalysed requirements	224
*iso*Leucine or valine	1		
Leucine	15		
Lysine	10		
Methionine	23		
Phenylalanine	1		

(3) The production of auxotrophic mutants in the range tested (4 per cent of surviving cells were auxotrophs) follows a double-hit curve (Fig. 2).

(4) When suspensions are used the cells of which are in different metabolic states, the percentage of mutants induced by nitrous acid is independent of

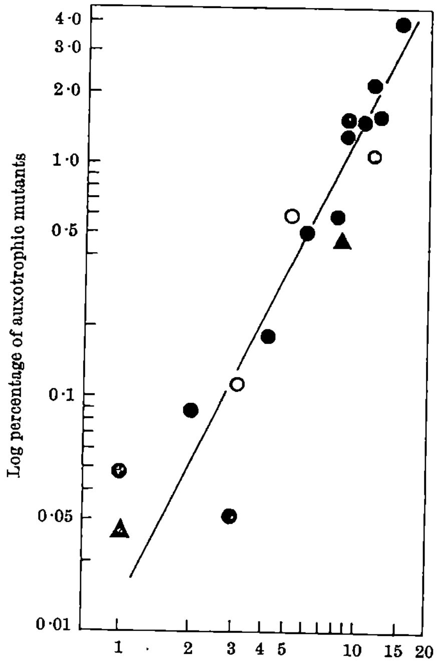

Fig. 2. Relationship between the percentage of induced mutants and the time of incubation with 0·017 *M* nitrous acid (*p*H 4·5). Since the plot is a straight line with a slope of about 60° when both axes have the same logarithmic scale the curve is evidence for a double-hit reaction. ●, Resting cells of *E. coli*, strain *B*; ○, cells from a growing culture of *E. coli*, strain *B*; ▲, resting cells of *Salmonella typhimurium*, strain *LT* 2

the rate of inactivation (Fig. 2) and depends only on *t*. Thus the rate of mutation is not influenced by the metabolic state of the cell. This is consistent with the hypothesis that the mutational effect of nitrous acid on living bacteria is direct, that is to say, due to the conversion of adenine, guanine and cytosine present in the deoxyribonucleic acid into hypoxanthine, xanthine and uracil.

(5) From 600 auxotrophic colonies which arose from bacteria plated directly after contact with nitrous acid, none was sectored even with survival rates higher than 5×10^{-1}, nor did any contain wild-type cells. This is contrary to the results of work[4] with phosphorus-32 incorporated into living bacterial cells; in which case the mutagenic effect of disintegrating phosphorus-32 gave cells which formed colonies composed of auxotrophic and prototrophic sectors. The lack of sectored colonies after treatment with nitrous acid, together with the double-hit type of the mutation curve, leads to the conclusion that in order to cause a mutation which is detectable under the experimental conditions applied, nitrous acid must affect both strands of the double-helix of the deoxyribonucleic acid molecule.

I am much indebted to Prof. G. Schramm and Dr. H. Schuster for discussions of this work, a detailed account of which is in preparation.

BIOLOGY

Effect of Gibberellin on the Termination of Dormancy in Some Seeds

ALTHOUGH the effect of gibberellin on certain growth processes has been extensively studied in recent years[1,2], few reports have been published on the influence of this compound on germination of seeds. Lona[3] and Kahn, Goss and Smith[4] have shown the effect of gibberellin on lettuce seeds. In these, as well as in *Arabidopsis* studied by Kribben[5], gibberellin apparently can substitute for red light necessary for germination of the seeds of these species. Also in the experiments of Bünsow and Bredow[6] the promoting effect of gibberellin on the light-sensitive seeds of *Kalanchoë* is observed. The effect of gibberellin on the revitalization of old seeds is also mentioned[2]; but this is all that has come to our notice.

We have conducted experiments to determine the effect of gibberellin on the germination of seeds of various plants which were collected in the autumn of 1958 in the vicinity of the Arctic Biological Station of the University of Turku at Utsjoki in the northernmost part of Finland (latitude 69° 45′).

Gibberellin (Chas. Pfizer and Co., Inc., New York) was found to exert a marked influence on the germination of the seeds of eight of about the 50 species examined. These eight species are *Luzula parviflora*, *Trollius europaeus*, *Erysimum hieraciifolium*, *Draba hirta*, *Geranium silvaticum*, *Diapensia lapponica*, *Gentiana nivalis* and *Bartsia alpina*.

The germination experiments were performed on filter paper in a Johnson germinator at a temperature of 24° C., and in diffuse daylight conditions.

Because the effect of gibberellin was first observed in the experiments on *Gentiana nivalis* seeds, these have been studied most thoroughly to date. In October 1958 not a single one of 500 seeds germinated in the control experiments (that is, on filter paper), and light as well as cold treatment of 20 days duration had no effect. The results obtained when the seeds were exposed to the action of gibberellin are shown in Table 1. In these conditions the germination took place on the sixth day (Table 1).

Table 1. THE EFFECT OF GIBBERELLIN ON THE GERMINATION OF *Gentiana nivalis*. (PERCENTAGE GERMINATION)

Time of exposure	Gibberellin (per cent)				
	0·5	0·25	0·1	0·01	0·001
1 hr.	100	100	100	1	0
3 hr.	100	100	100	4	0
6 hr.	100	95	97	45	0
8 hr.	90	92	91	70	6
24 hr.	80	95	90	76	22

When the experiments were repeated in February 1959 on seeds that had been stored in the laboratory, none of the control series germinated and the effect of gibberellin on the exposed seeds was the same as in the autumn experiments. In the later part of March the effect of the weak concentrations 0·01 is more effective than in the autumn, the germination percentage being after the treatment of 3 hr. as much as 85 per cent.

Table 2 shows the results of experiments in which the seeds of *Erysimum hieraciifolium*, *Draba hirta*, *Bartsia alpina* and *Luzula parviflora* were exposed to 0·1 and 0·01 per cent solutions of gibberellin.

Table 2. PERCENTAGE OF GERMINATION OF FOUR DIFFERENT SPECIES PRETREATED WITH GIBBERELLIN

	Gibberellin (per cent)	3 hr.	6 hr.	24 hr.	Control
Erysimum hieraciifolium	0·1	85	100	100	25
	0·01	90	100	100	
Draba hirta	0·1	16	20	95	0
	0·01	5	5	10	
Bartsia alpina	0·1	10	80	90	5
	0·01	10	45	85	
Luzula parviflora	0·1	10	10	90	10
	0·01	5	15	90	

In the case of *Trollius*, prolonged soaking in gibberellin solution is necessary to effect germination. After 24 hr. 15 per cent of the seeds exposed to 0·1 per cent gibberellin and 5 per cent of seeds exposed to 0·01 per cent gibberellin germinated, whereas after 48-hr. treatment the respective percentages were 90 and 80.

It is obvious that gibberellin penetrates into the embryo of the *Trollius* seed very slowly. A preliminary treatment with sulphuric acid therefore was given. Seeds pretreated with sulphuric acid for 20 min. germinated to the extent of 70 per cent when they were exposed to a 0·01 per cent gibberellin solution for 3 hr.

The germination experiments with *Diapensia lapponica* were carried out in February 1959. 15 per cent of the seeds exposed to a 0·1 per cent gibberellin solution for 24 hr. were germinated whereas none of the seeds of the control series germinated.

A combination treatment with sulphuric acid and gibberellin gave the best results with *Geranium silvaticum*. The seeds stored in normal room condition germinated very poorly, the germination being less than 1 per cent. Exposure to gibberellin solutions had no effect, and exposure to concentrated sulphuric acid only a slight effect. When, however, the acid-treated seeds were exposed to the gibberellin solution, a very high proportion of the seeds germinated. The most favourable procedure was to treat the seeds first with concentrated sulphuric acid for 30 min. and, after washing, to 0·1 per cent gibberellin for 6 hr. Prolongation of the latter period of exposure to 24 hr. did not increase the proportion of germinated seeds.

No correlation between systematic relations and the effect of gibberellin was established. Seeds of *Gentiana uliginosa* and *G. amarella* from southern Finland and *Luzula sudetica*, *L. pallescens*, *L. spicata*, *L. multiflora* and *Draba incana* did not respond to the treatment with gibberellin. Strains of *Erysimum hieraciifolium* from southern Finland and Poland did not differ significantly from the strains from northern Finland.

Some Unusual Outgrowths from Secondary Follicles in Soay Sheep

SOME 'plugs' of undifferentiated cells were discovered while the secondary : primary follicle ratio was being determined in preparations of skin from four six-month old Soay lambs. The plugs were found at the sebaceous gland level, and were traced towards the skin surface through the series of sections in order to determine whether they were developing follicles, shedding follicles, or parts of sebaceous glands.

In fact, each plug joined on to the ectal side of a secondary follicle immediately beneath the epidermis and thus arose as an outgrowth. They are thought to be follicle branches that have occurred during the development of follicles[1]. But they were also found in two adults, 3 and 4 years old. The original samples were taken in September 1958; and skin obtained later when two of the lambs were slaughtered unfortunately did not give sufficiently good preparations to show these outgrowths. But a third adult, two years old, sampled in February 1959, had them.

Four of the six outgrowths traced in detail had a lumen extending 60–80μ below their attachment (Fig. 1). This joined the follicle lumen and was either lined or blocked with stratum corneum in the upper part, so that here the outgrowth resembled the sweat duct of a primary follicle. Below this the lumen was blocked discontinuously with pigment. On the termination of the lumen at the sebaceous gland level of the parent follicle the cells of the outgrowth became undifferentiated, usually on the side adjacent to the follicle, but on the opposite side they had the appearance of sebaceous cells for 25–60μ. One outgrowth (in an adult) in fact had an outgrowth of sebaceous tissue in the shape of a sebaceous gland. Below this the cells appeared undifferentiated for the remaining 80–100μ of the length of the outgrowth. Another outgrowth, however, had a bud of undifferentiated cells immediately below the sebaceous portion.

Undifferentiated epidermal cells

Fig. 1. Left, diagram of outgrowth reconstructed from a series of tracings of cross-sections made with a projection microscope; right, some of the cross-sections

One outgrowth (in a lamb) was apparently at an early stage of development in that the cells had an undifferentiated appearance over the whole of its length, and the lumen appeared discontinuously in short lengths. Another (in an adult) was apparently more advanced because it had fragments of inner sheath in the lumen, but there were no traces of fibre.

Most of the outgrowths were apparently attached to the sebaceous gland and sometimes to the outer sheath of the parent follicle, and one was attached to the outer sheath of another follicle. This attachment does not seem to be close, however, but has arisen only from the contact of undifferentiated tissue. At the level of the contact with the sebaceous gland the undifferentiated tissue was inconspicuous, being confined to a narrow strip at the edge of the gland, and in horizontal section there was little to show that the sebaceous gland was other than normal.

Most of the fibres of the Soay are pigmented, and although the outgrowths were frequently pigmented it was noticed that the fibre of the parent follicle was often the only non-pigmented one in the group. This suggested that the growth of the fibre had become less vigorous. The percentage of secondary follicles with these outgrowths ranged from 1 per cent in one of the adults to 23 per cent in one of the lambs. From Table 1 it will be seen that as the percentage of outgrowths decreases, the ratio of mature secondary follicles to each primary increases.

Table 1

	Lambs				Adults	
Percentage of secondary follicles with outgrowths	31	27	20	10	6	1
Mature *S/P* ratio (S_F/P_F)	2·47	2·61	2·99	2·88	3·6	4·64

These outgrowths are thought to have no relation to the outgrowths called capsules[6], which are now thought to be milia (benign tumours). Their appearance near the skin surface suggested that they were sweat glands, and it was thought that their parent follicles may have been intermediate between primary and secondary follicles as described by Burns[2]. However, the outgrowths bear much resemblance to developing follicles; they are very similar in appearance to the developing follicle shown in ref. 3, Fig. 23, and they are on the same side of the follicle as the follicle branches of Hardy and Lyne.

The chief way in which they differ from the developing follicles in fœtal skin of the Romney breed[4] is that the lumen joins the follicle lumen and contains much stratum corneum. The comparable part in a developing follicle, the hair canal, does not open to the surface until the wool fibre pierces the epidermis. In addition, the outgrowths are clearly much retarded when compared with normal developing follicles. Some other skin from a Soay lamb at birth showed many developing follicles, and the *S/P ratio* was already approaching the adult value[5] of about 5/1. Possibly the evidence which suggested most strongly that these outgrowths represent developing follicles comes from the trend in Table 1, in which the *S/P* ratio of follicles with fibres increases as the proportion of outgrowths decreases.

The attachment of the outgrowth to its parent's sebaceous gland seems to be abnormal. But this may throw light on the development of sebaceous tissue because it was always at the level of the parent's sebaceous gland that the cells of the outgrowth became sebaceous-like. It may be that here the undifferentiated cells are under the influence of an organizer from the parent's sebaceous gland which leads to their development into sebaceous cells.

Relationship between the Hake Fishery and a Southerly Sub-surface Return Flow below the Peru Current off the Chilean Coast

A COMBINED hydrographic and biological investigation has been launched jointly by the Department of Fish and Game of the Ministry of Agriculture of the Republic of Chile and the Technical Foreign Aid Program of the Federal Republic of Germany in order to find possible relationships between the migration and behaviour of fish and the changing hydrographic conditions off the Chilean coast.

The hake, *Merluccius gayi gayi* (Guichenot), is the most important fish to the economy of Chile. More than 50 per cent of the total landings of all species consists of hake. The main trawling grounds are the banks at a depth of 100–150 metres between Papudo (lat. 32° 30′ S.) and the Gulf of Arauco (lat. 37° 15′ S.). Since the continental shelf is very narrow along the Chilean coast, the hake fishery takes place within 10 miles of the shore line. The fish are caught mainly off Valparaiso, San Antonio and Talcahuano. In the northern zone of Valparaiso area, the best fishing occurs during the months September–December, with a steep maximum in the catch statistics in October or November. A sharp drop of the catches to almost zero follows after December. In the Talcahuano area we find moderate catches throughout the year but a pronounced maximum in March (Fig. 1). The yield in the San Antonio area is intermediate. It seems that the stock of hake migrates successively from the northern area of Valparaiso southward, and later in September back to the north.

A preliminary hydrographic survey, carried out off Valparaiso in February 1959, shows extremely interesting results with regard to the oxygen of the water which covers the hake fishery banks (Fig. 2). The oxygen content of the water in an intermediate layer between 100 and more than 380 m. depth (possibly deeper, but no more wire was available) is between 1·0 and 0·4 ml./l., which suggests that the hake has been pushed southward by the lack of oxygen in the water.

By means of salinity and temperature sections off Peru and northern Chile, Gunther[1], proved the existence of a sub-surface return flow below the Peru Current at a depth between 200 and 400 m. Since plankton production in the Peru Current is very high[2], the decomposition of organic material, which sinks into the return flow beneath, apparently causes great depletion of oxygen in this layer. Similar conditions have been found in the north-east Pacific[3].

In Chilean waters there is only Gunther's work, based on the temperature and salinity observations obtained during the cruise of the *William Scoresby* in 1931. We do not know how far this oxygen-poor water extends to the south, how far offshore it extends to the west, and how deep it is. According to the salinity sections drawn by Gunther[1], it seems that this sub-surface current is pushed towards the coast by the effect of the Coriolis force. By changes of some kind in the hydrographic or meteorological conditions, this water covers the hake-fishery banks at certain times of the year, affecting the migration of the hake, and consequently determining the yield of the fishery in the three zones.

The investigation will be continued and a detailed report published later elsewhere.

Life-Span of Rat and Mouse Erythrocytes in the Rat–Mouse Chimera

THE secondary disease observed in irradiated animals treated with foreign bone marrow is of general interest and importance. The basic question which remains unanswered is whether immunologically competent cells in the chimera originate from the donor, the host, or a combination of both. Erythrocyte life-span studies might be expected to throw light on whether this secondary reaction, in so far as it is reflected in red cell survival, is of host or of donor origin.

Nine $(C57 \times 101)F_1$ female mice that survived 60 days after 900 r. of X-rays (LD100/20 days) and an injection of Sprague–Dawley rat bone marrow (55×10^6 nucleated cells/mouse) on day zero were transfused intravenously with 0·2 ml. of a 45 per cent suspension of chromium-51-labelled red blood cells in saline. Four mice were given labelled isologous erythrocytes and five were given labelled rat erythrocytes; blood was pooled from normal donors for each group. The activity of chromium-51 in circulating blood measured at 24 hr. was taken as 100 per cent, and measurements were made at intervals for 7 weeks. 25 days after the transfusion of labelled cells these animals had essentially 100 per cent rat erythrocytes by the mannitol test[1].

The level of activity of chromium-51 is plotted against time in Fig. 1, and it can be seen that the rat cells disappeared more rapidly in the chimera than did the mouse cells. The latter followed a normal life-span curve for this strain. The curve for rat erythrocytes is intermediate between that for rat cells in the normal rat (maximum life span: 60 days) and that for rat cells in the normal mouse (maximum life span: 4 days) (Smith and Tohá[2]). It was found by Smith and Tohá[2] that rat cells from a rat–mouse chimera survived in normal recipients like cells from a normal rat.

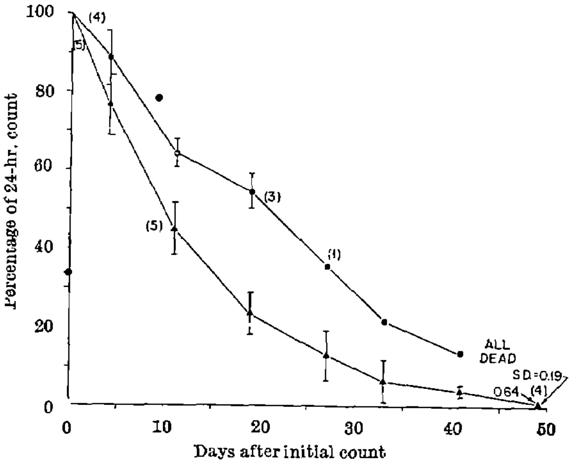

Fig. 1. Disappearance of chromium-51 activity from the circulating blood of rat–mouse chimeras transfused on day zero minus one with either mouse (upper curve) or rat (lower curve) labelled erythrocytes. Number of surviving animals in each group is shown in parentheses at three time points on the curves. Standard deviations are indicated by vertical bars at each point plotted

It is clear from these preliminary results that the long-term heterologous chimera, although 100 per cent of its circulating erythrocytes are of rat origin, provides an imperfect environment for rat red blood cells. On the other hand, the presence of active rat hæmatopoietic tissues in such a host does not influence the survival of transfused mouse erythrocytes. This study therefore provides no evidence of an active rat immune system. Whether the accelerated destruction of rat cells reflects a recovering host immune system, as is clearly indicated by the findings of Gengozian *et al.*[3], or only the foreign biochemical and physiological environment of these heterologous cells cannot be answered by these data.

Assortative Mating and Reciprocal Difference in the Blue–Snow Goose Complex

THE lesser snow goose *Chen hyperborea* and the blue goose *Chen caerulescens* are maintained as good species by the standard taxonomic works[1] though the morphological difference between them is confined to colour of plumage. The geographical distribution of the two is different. The snow goose ranges through Siberia, western Canada, the Hudson Bay area and Baffin Island; west of Banks Island the populations are unmixed. To the east, however, most populations contain some blue geese and in the Bowman Bay area of Baffin Island there exist several populations in which more than 90 per cent of the birds are blue. Where the populations are mixed, interbreeding between the two occurs, and the progeny produced are viable, fertile[2] and phenotypically distinct[3]. This has led some authorities[4] to consider the two forms to be polymorphs of one biological species. This communication is concerned with observations made by one of us (F. G. C.) on breeding behaviour in the mixed Boas River population, and for convenience the terms blue and snow are used in a purely descriptive sense. Table 1 shows the observed and expected (random mating) distribution for three

Table 1. OBSERVED AND EXPECTED DISTRIBUTION OF DIFFERENT MATINGS IN A MIXED BLUE AND SNOW GOOSE POPULATION

Type of mating	Two snow birds	Two blue birds	One blue, one snow	Total
No. observed	373	64	83	520
No. expected	330·4	21·4	168·2	520

types of mating: (1) both snow birds; (2) both blue birds; (3) one snow and one blue bird in a random sample of 520 breeding pairs from the Boas River population in 1952.

The χ^2 value for the deviations from expected is very large, 133·45, which for 3 degrees of freedom indicates a probability of less than one in a thousand of obtaining such a result by chance alone.

This is strong evidence for the existence of positive assortative mating in mixed populations and this is in agreement with earlier work[5,6].

In our study, however, the reciprocal matings snow × blue and blue × snow were distinguished. Table 2 shows for the 83 mixed pairs the observed and expected distribution.

Table 2. OBSERVED AND EXPECTED DISTRIBUTION OF THE TWO RECIPROCAL TYPES OF MIXED MATING IN A MIXED BLUE AND SNOW GOOSE POPULATION

Type of mating	Snow (♀) and blue (♂)	Blue (♀) and snow (♂)	Total
Observed	54	29	83
Expected	41·5	41·5	83

The χ^2 value for the deviations in this case is 7·52 for 1 degree of freedom. The probability that this is the result of chance alone is less than one in a hundred. We may feel, therefore, confident that the incidence of the two reciprocal matings is really different in this, and presumably in other mixed populations, and it is of some evolutionary interest to speculate as to possible reasons for this. One reason may be that the sex ratio is different in the two phases. There are no indications that this is in fact true, but a sex ratio disturbed in the direction of relative female preponderance in snow geese and in the direction of relatively more males in the blue geese might give the effect observed.

A more likely hypothesis is that the mechanism governing resistance to unlike-mate choice more readily breaks down in one type of pair formation than in the other. This might involve different levels of receptivity on the part of the two female types, different levels of sexual drive on the part of the two male types or both. Only a study of the long-term dynamics of the mating barrier would tell us what factors are involved, but from other evidence it is possible to infer what might be happening. The frequency of the blue phase is increasing in all known mixed populations and more populations are becoming mixed; in the Darwinian struggle for existence it seems that the snow phase is losing to the blue and what is observed at present is a transient polymorphism (which may, of course, later become balanced).

Among other things one component of the selective advantage enjoyed by the blue phase may be sexual in that blue males find it easier to obtain an unlike mate than do snow males. The situation is complicated by the fact that the majority of blue birds involved in mixed matings are white-bellied (that is, heterozygous at the principal genetic locus governing difference in colour). This then implies that hybrid males may mate more easily than pure blue males, and in an evolutionary sense this might be a factor in promoting a balanced polymorphic system in the species-complex but equilibrium is so far from being attained than further speculation upon this point seems unwarranted.

Whatever the mechanism underlying the reciprocal mating difference, it is clear that it depends upon factors other than those which are responsible for assortative mating as such, although this is in itself a matter of considerable interest. Further study should show how far mating preference is a result of family structure[4], imprinting[7], pleiotropy of colour genes or more complex genetic systems, and will, it is hoped, contribute towards a better understanding of the taxonomic problem.

Hæmoglobin and the Habitat of the Harpacticoid Copepod *Elaphoidella gracilis* (Sars)

HÆMOGLOBIN has only recently been found in free-living copepods. Munro Fox[1] found that certain mud-dwelling harpacticoids contained this respiratory pigment, while allied species living in moss or open water lacked it. The correlation between hæmoglobin and habitat can now be extended by the discovery of hæmoglobin in *Elaphoidella gracilis*, a species which inhabits burrows in decaying aquatic vegetation. The red pigment in this species is easily visible under the microscope, and its identity was established spectroscopically.

Elaphoidella gracilis is not very often recorded because of its burrowing habits. Gurney[2], writing of its seasonal occurrence, says "the capture of it is so capricious that nothing certain is known". Donner[3] regards it as a summer form, but I have found this species to be present and active in the Long Water at Hampton Court throughout the whole of the last winter.

Role of the Supra-œsophageal Ganglion during the Early Stages of Caudal Regeneration in Some Errant Polychætes

THE importance of the nervous system in annelid regeneration has been realized for some years[1], and it has emerged that, at least in lumbricid oligochætes and nereid polychætes, the supra-œsophageal ganglion secretes hormones that are essential for regeneration[2-4]. Durchon[3] showed that if the supra-œsophageal ganglion of three species of nereid is removed regeneration is retarded. Hubl[4] discovered that, in lumbricids, extirpation of the supra-œsophageal ganglion at the same time as a number of posterior segments is removed totally inhibits posterior regeneration, but that if the brain is removed 24–48 hr. after the posterior segments are amputated then posterior regeneration proceeds at the normal rate. There is thus a brief critical period during which the brain exerts its influence in initiating regeneration. Since Durchon extirpated the brain of his animals 24 hr. after amputating the posterior segments, it is not clear if the difference between his results and those of Hubl represents a real difference between lumbricids and nereids, or if it is due to the difference in experimental procedure.

Durchon's experiments have been repeated on *Nereis diversicolor*[5], and it has been found that extirpation of the supra-œsophageal ganglion 24-hr. before amputation of a number of posterior segments totally inhibits the proliferation of new segments, though one-third of the animals regenerate a pygidium. If the ganglion is extirpated 72 hr. after amputation of the posterior segments, regeneration is retarded, but not prevented, and 16 per cent of the animals proliferated 1 segment during the 30 days the experiment was continued. During this time, control animals regenerated between 1 and 11 segments (average 4).

The events occurring in the regenerating tip, the brain and the blood vascular system during the five days following the loss of posterior segments have been followed in more detail in *Nephtys cirrosa* and *N. hombergi* (members of the Nephtyidae, a family of polychætes closely related to the Nereidae).

During this period the wound is closed and, after an initial stage of dedifferentiation, blastema-formation and regeneration begin. Between the first and second days, muscle cells begin to dedifferentiate, and there is an accumulation of cœlomocytes at the wound. Cell division does not occur until the second day and is then confined to the gut epithelium and to a few dedifferentiated mesenchyme cells. By the third day, mitoses are common in the preterminal part of the nerve cord, and it is not until the fourth day that mitoses occur in the tip of the nerve cord and in the epidermis.

Within 6 hr. of amputation of a number of segments, neurosecretory cells in nucleus S[6] of the supra-œsophageal ganglion become active. After about 48 hr. the secretory cell-nucleus becomes very angular, the cytoplasm of the cell is vacuolated and appears to be depleted of its secretion. No more than one or two cells on either side of the ganglion are involved. Cells in ganglionic nucleus Z show visible signs of secretory activity 24–48 hr. after the loss of the segments. These cells become depleted of their secretion within a further 24 hr., but others in the same ganglionic nucleus start to secrete and replace them. A few cells in this nucleus contain neurosecretory material even in worms that have regenerated 12 or more segments. The secretion produced by both sets of cells migrates along the axons and those from ganglionic nucleus Z run to the cerebro-vascular complex at the base of the ganglion where neurosecretory material is released into the blood vessels[7].

Neurosecretory material is taken up by blood corpuscles[7], and these increase enormously in number during the early stages of regeneration. Initially, no more than one or two can be counted in the blood vessel beneath the brain; their numbers begin to increase about 12 hr. after amputation, and by the fifth day nearly 70 can be counted in the same length of blood vessel. A comparable increase in the number of blood corpuscles can be detected in vessels near the regenerating tip.

Detailed accounts of this work will be published elsewhere.

The Proposed Biological Term 'Pheromone'

Karlson and Lüscher[1] have recently proposed the term 'pheromone' for a class of substances which, while resembling hormones in some respects, cannot be included among them because they are not of an endocrine origin. It is claimed that the latter part of the proposed word is derived from the Greek *hormōn* (which should properly be *hormān*), meaning 'to excite'. This is not so. It was apparently the intention of the authors to find a term which, while being derivable from *hormān*, bore little overt resemblance to the word 'hormone'. This they achieved by the improper expedient of dropping the letter 'r', thus mutilating the root of the Greek word. It should be a principle, when a scientific term is derived from classical origins, that the term must by its structure be traceable to those origins. In the case of the word 'pheromone' that principle is not observed: there is no structural clue to its derivation from *hormān*. Indeed, the only Greek verb (apart from *pherein*) which might conceivably be involved in its ancestry means 'to swear'.

It would be an etymological improvement to re-instate the missing 'r', making 'pherormone'. If this too closely resembles 'hormone', an alternative would be to abandon Greek and use the word 'transcitant', derived from the Latin *trans* and *citare* (to excite). The approximate meaning, as well as the derivation, of this word is readily deducible—an advantage not shared by 'pherormone'.

H. S. Micklem

Radiobiological Research Unit of the
Medical Research Council,
Atomic Energy Research Establishment,
Harwell, Berks.

[1] Karlson, P., and Lüscher, M., *Nature*, **183**, 55 (1959).

It was our aim to introduce, for a class of substances, a scientific term of international usefulness. Based on a clear definition, it should be a short word easily pronounced in many languages. This is not the case with 'pherormone'. It must be admitted that the derivation of 'pheromone' from *hormān* is questionable. We would therefore not insist on it; but we regard the ending 'mone' as a proper suffix which is used in hormone, gamone, termone and pheromone.

The alternative proposal 'transcitant' is regarded as unfortunate. Its translation would refer to a neurohumoral transmitter substance rather than to a pheromone. The exciting activity is only one of their possible actions. Furthermore, the parallelism to hormone, gamone, etc., is entirely lost.

P. Karlson
M. Lüscher

INDEX

ABBOTT, Bernard C., and others : Electrical Response to Illumination of the Euphausiid Crustacean Eye, 1820
Abd-El-Malek, A. S. (Soliman, F. A., and) : Influence of Temperature and Light on Reproduction in Male Rats, 266
Abd-el-Wahab, Dr. A.: A New Method for Delaying Pupation in *Drosophila melanogaster*, 127
Abels, Dr. J., and others : Ethylenediamine Tetraacetate and the Intestinal Absorption of Vitamin B_{12}, 1395
Abelson, Dr. Philip H. : Elected a member of the United States National Academy of Sciences, 1575
Abercrombie, D : Phonetics, *review*, 209
Aberdeenshire Dee : *Vibrio* spp. in Finnock from the (Isabel W. Smith), 1409
Aberrant Cell Walls and of Spores : Formation of, by the Growing Yeast Protoplast (A. A. Eddy and D. H. Williamson), 1101
Aberration of the Connective Tissue : Human Muscular Dystrophy as an (Prof. Geoffrey H. Bourne and M. Nelly Golarz), 1741
Aberrations (Chromosomal) : A New Physical Method of creating (Dr. John H. Heller and Dr. A. A. Teixeira-Pinto), 905
Aberystwyth Area : The Soils of the (Welsh Soils Discussion Group Discussion on), 865
Abnormal Development of the Basis in *Balanus amphitrite* var. *stutsburi* Darwin (Dr. H G. Stubbings), 1282
Abnormal Haemoglobins (Normal and Doubly) : Formation of, by Recombination of Haemoglobin I with S and C (Constituents of Human Haemoglobin), (Dr. Harvey A. Itano and Elizabeth Robinson) 1799
Abnormal Proteins in Myeloma and Macroglobulinaemia : Starch Gel Electrophoresis Studies on (Dr. J. M. Fine and Dr. R. Creyssels), 392
Abnormal Resistance of *Poria vaillantii* (D. C. ex Fr.) Cke. Strains to Copper–Chrome–Arsenate Wood Preservatives (E. W. B. Da Costa), 910
Abnormality : A Rare Sperm—'Corkscrew-sperms' associated with Sterility in Bulls (Dr. Erik Blom), 1280
Abnormality in the Skin of Sheep (Mary Dempsey and G. H. Green), 909
Aboriginal Art, *review* by Dr. Phyllis Kaberry, 1080
Abscission-Accelerating Substance in Senescent Leaves : Identity of the (Daphne J. Osborne), 1593
Abscission-Accelerators in Lupins (*Lupinus luteus* L.), (R. F. M. Van Steveninck), 1246
Absence of Gibberellin-like Substances in Filtrates of *Marasmius perniciosus* Stahel (Witch Broom Disease of Cacao), (W. F. Dudman and R. Nichols), 899
Absence of Homotransplantation Reaction : Antibody Formation by Isolated Spleen Cells transferred to Recipients in (Dr. Z. Trnka and I. Říha), 546
Absence of a Relation between Lipogenesis and Ketogenesis *in vivo* (Dr. P. A. Mayés), 540
Absolute Measurement of the Intensity of the (111) Reflexion for Diamond (Prof. R. Brill and H Zandy), 1387
Absorbing Bodies : Initiation of Thermal Reactions by the Flash Illumination of (Dr. J. L. Lundberg and Dr. L. S. Nelson), 1560
Absorption of Alkali Cations by Plant Tissue Cultures (Dr. J. F. Sutcliffe and E. R. Counter), 1513
Absorption of Orally Administered Vitamin B_{12} : Effect of D-Sorbitol on the (Dr. J. N. Marshall Chalmers and N. K. Shinton), 120
Absorption of Radioiodine through the Bladder-Wall in the Rabbit (Oskar Andrysek and Ota Schück), 893
Absorption (Faecal), of Radioactive Ferric Chloride : Effect of Dietary Phytate on (Dr. Henry Foy, Athena Kondi and W. H. Austin), 691
Absorption (Intestinal), of Vitamin B_{12} : Ethylenediamine Tetraacetate and the (Dr. J. Abels, M. G. Woldring, H. O. Nieweg, J. G. Faber and J. A. de Vries), 1394
Absorption Spectra and Associated Photoconductivity of Pure and Decomposed Crystals of Thallous Azide (B. L. Evans and A. D. Yoffe), 1241
Absorption Spectra (Infra-red and the Near Ultra-violet), of Polyphenyl Derivatives of the Elements of Groups IV*b* and V*b* (Dr. C. N. R. Rao, J. Ramachandran, M. S. C. Iah, S. Somasekhara and T. V. Rajakumar), 1475
Absorption Spectrum and Decay Kinetics of the Metastable State of Chlorophyll *b* (Prof. Stig Claesson, Lars Lindqvist and Bertil Holmström), 661
Academic Freedom and the Universities of South Africa, 1551
Academic Studies : The Scope of Physical Anthropology and its Place in—a Symposium held at the Ciba Foundation, 1957 (edited by D. F. Roberts and J. S. Weiner), *review* by Dr. Kenneth Little, 70
Academy of Sciences of the U.S.S.R. : An English translation of the *Astronomical Journal* of the, to be published by the American Institute of Physics in co-operation with the National Science Foundation, under the title *Soviet Astronomy—AJ*, 1164
  A. S. Popov Gold Medal awarded to Dr. Louis Essen, 1502
  Fizika Tverdogo Tela (Soviet Physics—Solid State), No. 1, 1717
Accelerating (Abscission-) Substance in Senescent Leaves : Identity of the (Daphne J. Osborne), 1593
Acceleration of Artificial Satellites : Corpuscular Radiation and the (Dr. Luigi G. Jacchia), 1662
Acceleration of Ciliary Activity by Negative Air Ions : An Enzymatic Basis for the (Prof. A. P. Krueger and Richard F. Smith), 1332
Acceleration (Orbital), of Artificial Satellites : Two Atmospheric Effects in the (Dr. Luigi G. Sacchia), 526
Accelerators (Abscission-) in Lupins (*Lupinus luteus* L.), (R. F. M. Van Steveninck), 1246
Accelerators (High Energy), and Instrumentation (C. E. R. N. International Conference on), 1783
Acceptance (Food) : Flavor Research and—a Survey of the Scope of Flavor and Associated Research compiled from papers presented in a series of Symposia given in 1956-57, *review* by Dr. Magnus Pyke, 351
Accessory Limb Formation in Urodeles : Delayed Denervation and (Dr. Laurens N. Ruben), 765
Accident (Windscale Reactor) : Measurements at Leeds following the—Iodine-131 in Human Thyroids and Iodine-131 and Caesium-137 in Milk (Dr. P. R. J. Burch), 515 ; Increase in Background Gamma-Radiation and its Correlation with Iodine-131 in Milk (Prof. F. W. Spiers), 517
Accidents (Road) : Research on the Prevention of, 649
Acephaline Gregarine (*Apolocystis elongata*, Phillips and MacKinnon) : Observations by Electron Microscopy on the Structure of an (Dr. D. Lacy and H. B. Miles), 1456
Acetabularia : Action of Auxins on, and the Effect of Enucleation (Prof. Kenneth V. Thimann and Dr. Kurt Beth), 946
Acetamidomalonate (Diethyl) : Asymmetric Hydrolysis of, by Chymotrypsin (Prof. Saul G. Cohen and Lucille Altschul), 1678
2-^{14}C-Acetate and ^{14}C-Glucose in *Trichoderma viride* : Synthesis of Long-Chain Fatty Acids from (Dr. W. Mary Crombie and P. E. Ballance), 1195
Acetate (Cellulose), as a Medium for Immuno-Diffusion (R. Consden and J. Kohn), 1512
Acetate (Cellulose) Membranes suitable for Osmotic Measurements (M. F. Vaughan), 43
Acetate (Cellulose) Membranes used for Zone Electrophoresis : Regeneration of (Dr. S. Jacobs), 1326
Acetoacetate Metabolism of Liver Homogenates of Normal and Alloxanized Rats : Action of Nicotinamide on (S. Eser, S. Tekman and A. Araz), 184
Acetoacetate (Glucose-*cyclo*-), as a Precursor of Ascorbic Acid in Germinating Green Gram (Prof. M. C. Nath and M. L. Belkhode), 1258
Acetobacter xylinum : Synthesis of Cellulose in Ethanol Extracts of (Dr. J. Ross Colvin), 1135
Acetone : Relaxation of Glycerol-treated Muscle Fibres by (Dr. Setsuro Ebashi and Dr Fumiko Ebashi), 687
Acetone (Cobalt Chloride–Water–) : Existence of Two Liquid Phases in the System (Dr. J. N. Murrell, Dr. L. I. Katzin and B. L. Davies), 459
Acetylcholine : Distinction between Sodium and Potassium in Change in Permeability effected by Lipid-soluble Analogues of (Dr. Wolf D. Dettbarn), 465
Acetylcholine Release : Failure of, in Tick Paralysis (Patricia Emmons and Prof. H. McLennan), 474
Acheson Colloid, Ltd. : A Dispersion of Polytetrafluoroethylene under the trade name of 'Emralon', 1501
Acheta commodus W. : A Rapid Method for examining Diapause Embryos of (T. W. Hogan), 269
Acid from Arabinose and Xylose : Production of, by Strains of *Azotobacter* (Vagn Jensen), 1536
Acid Mucopolysaccharides of Normal Urine (Dr. J. F. Heremans, J. P. Vaerman and M. Th. Heremans), 1606
Acid Phosphatase-elevating Activity : Fractionation of Brain Extracts for (Dr. V. Schreiber, Prof. J. Charvát, V. Kmentová and M. Rybák), 473
Ackeret, Prof. J. : Honorary Fellowship of the Royal Aeronautical Society conferred on, 1648
Ackerknecht, Prof. Erwin H. : The Quintessence of Paracelsus, *review*, 1147
Ackroyd, J. F. : Immunological Aspects of Allergic Disorders (Allergic Thrombocytopenic Purpura due to Antazoline), 297
Acoustic Orientation of Bats and Men : Listening in the Dark, the (Prof. Donald R. Griffin), *review* by Prof. R. J. Pumphrey, 1554
Acoustics : Musical (Prof. E. G. Richardson), 1293
  Of What Use is, to the Musician ? (Acoustics Group of the Physical Society Discussion on), 1293
Acoustics (Physical), and the Properties of Solids (Dr. Warren P. Mason), *review* by Prof. E. G. Richardson, 1221
Acquired Characters : Canalization of Development and Genetic Assimilation of (Prof. C. H. Waddington), 1654
Acquired Immunological Tolerance of Heterografts (Dr. Milan Hašek, Tomàš Hraba and Jan Hort), 1199
Acridine Orange : Fluorescence of Tissue Culture Cells stained with (U. N. Joshi and Dr. K. S. Korgaonkar), 400
Acta Biologica Cracoviensia, Vol. I, No. I (Polish Academy of Sciences), 1781
Actidione (Cycloheximide) : Reversal of Antibiotic Action of, by Bivalent Metal Ions (M. Blumauerová and J. Stárka), 261
Action of Auxins on *Acetabularia* and the Effect of Enucleation (Prof. Kenneth V. Thimann and Dr. Kurt Beth), 946
Action of the Contact γ-Aluminium Oxide/Platinum : Structure and Mode of (Prof. Alfons Krause), 1615
Action of Diphosphopyridine Nucleotidases : Mechanism of (Prof. Spyridon G. A. Alivisatos), 1034
Action of Insulin: Mechanism of (A. Dunn, N. Altszuler, Prof. R. C. de Bodo, R. Steele, D. T. Armstrong and J. S. Bishop), 1123

INDEX

Action of Light on Visual Pigments—Vertebrate Lumi- and Meta-Rhodopsins (Dr. Ruth Hubbard, Paul K. Brown and Dr. Allen Kropf), 442 ; Lumi- and Meta-Rhodopsins of Squid and Octopus (Dr. Allen Kropf, Paul K. Brown and Dr. Ruth Hubbard), 446 ; Chicken Lumi- and Meta-Iodopsin (Dr. Ruth Hubbard and Dr. Allen Kropf), 448
Action of Nicotinamide on Acetoacetate Metabolism of Liver Homogenates of Normal and Alloxanized Rats (S. Eser. S. Tekman and A. Araz), 184
Action of Pyrrolizidine Alkaloids on the Neuro-Muscular Junction (Dr. C. H. Gallagher and Dr. J. H. Koch), 1124
Action of Ultra-violet Light on Skin—Effect of the Histamine Liberator 48/80 and Methotrimeprazine (Prof. S. Claesson, G. Wettermark and L. Juhlin), 1451
Action (Antibiotic), of Cycloheximide (Actidione) : Reversal of, by Bivalent Metal Ions (M. Blumauerová and J Stárka), 261
Action (Anticoagulant), of Fibrin Surfaces on Mammalian Blood (Dr. A. L. Copley, D. Steichele, M. Spradau and R. S. Thorley), 1683
Action (Anti-Thyroid), of β-Aminoethyl*iso*thiouronium Dibromide in Rats (John Osmer, Dr. Robert B. Jennings and Dr. Robert M. Dowben), 470
Action (Bacterial), in Pond-stored Logs (Eric L. Ellwood and Barton A. Ecklund), 1206
Action (Catalytic), of Copper in the Alkaline-Autoxidation of Cellulose at Low Alkali Concentration (R. I. C. Michie and Dr. S. M. Neale), 534
Action (Gene), in Erythrocyte Deficiency of Glucose-6-phosphate Dehydrogenase—Tissue Enzyme-Levels (Prof. Paul A. Marks, Dr. Ruth T. Gross and Dr. Ruth E. Hurwitz). 1266
Action (Inhibitory), of Amino-Acid Esters on the Production of Extracellular Amylase by *Penicillium chrysogenum* (Dr. L. Horváth, S. Bajusz and A. Szentirmai), 477
Action (Mode of), and Biological Properties of the S-(Methylcarbamyl) Methyl O, O-Dimethyl-Dithiophosphate (R. Santi and P. de Pietri-Tonelli), 398
Action (Protective), of Cystamine and 5-Hydroxytryptamine in Irradiated Rats : Effect of High Oxygen Pressure on the (H. A. S. van den Brenk and Ruth Moore), 1530
Action (Short-term), of Pepsin at Room Temperature : Splitting of the Electrophoretic Pattern of Serum Albumin during (E. Annau), 190
Actions (Pharmacological), of γ-Butyrobetaine (Dr. E. A. Hosein and Prof. H. McLennan), 328
Activated Sera : Granulocyte Precipitins of Human Tissues and (Dr. Leonhard Korngold, Gerda Van Leeuwen and Daniel G. Miller), 330
Activation of Amino-Acids in relation to the Synthesis of Silk Proteins (Prof. J. Heller, Dr. P. Szafrański and Dr. E. Sulkowski), 397
Activation of Thionophosphates by Liver Microsomes (Prof. R. D. O'Brien), 121
Activation (Organ), by Stress : Target (Prof. Jenö Kramár, Harry H. McCarthy, Margarete Simay-Kramár and Anthony J. Carnazzo), 1522
Activation (Stress), of Adrenal Glomerulosa (Dr. M. Hill, K. Dvořák and M. Pospíšil) 1819
Activator for Phospholipase *D* : Isolation of an (Herbert Weiss, Herbert E. Spiegel and Elwood Titus), 1393
Active (Immunochemically), Cross-linked Polystyrene (L. H. Kent and J. H. R. Slade), 325
Active (Optically), Fluorite Films (Niels O. Young and Jakym Kowal), 104
Active Substances (Biologically) : 'Pheromones', a New Term for a Class of (Dr. P. Karlson and Prof M. Lüscher), 55
Activities (Haemolysin and Complement-fixing) : Comparison of the Formation of the Complex, Sensitized Erythrocyte-Complement ($EAC'_{1,4,2}$) in Haemolytic Systems differing in their (Dr. Harold S. Goodman) 331
Activity of 10-Hydroxydecenoic Acid from Royal Jelly against Experimental Leukaemia and Ascitic Tumours (Prof. Gordon F. Townsend, Dr. Joseph F. Morgan and Dr. Barbara Hazlett), 1270
Activity (Acid Phosphatase-elevating) : Fractionation of Brain Extracts for (Dr. V. Schreiber, Prof. J. Charvát, V. Kmentová and M. Rybák), 473
Activity (Aminopeptidase), in Cancer Cells (R. G. J. Willighagen and H. T. Planteydt), 263
Activity (Anti-Tumour), of 5-Mercaptouracil (Thomas J. Bardos, Albert Segaloff and Julian L. Ambrus), 612
Activity (Antiviral), of Lysozyme (Prof. Rodolfo Ferrari, Dr. Carlo Callerio and Dr. Giuseppe Podio), 548
Activity (Arginine Esterase), of 'Blood Thromboplastin' (Phyllis M. Arscott, J. L. Koppel and John H. Olwin), 753
Activity (Biological), of L-Tryptophan Esters (Dr. Giulio C. Perri, Louis Kaplan and C. Chester Stock), 116
Activity (Blood-clotting), of the Venom of *Bothrops jararaca* (Dr. Olga B. Henriques, Dr. Fajga R. Mandelbaum and Dr. S. B. Henriques), 114
Activity (Cardiac) : Nucleotide Metabolism in (Dr. Philip A. Khairallah), 181
Activity (Ciliary), by Negative Air Ions : An Enzymatic Basis for the Acceleration of (Prof. A. P. Krueger and Richard F. Smith), 1332
Activity (Electric), in a Non-myelinated Nerve Ending : Spatial Summation of (Properties of a Receptor Membrane), (Prof. Werner R. Loewenstein), 1724
Activity (Enzyme) : Metals and (Biochemical Society Symposium No. 15, Leeds, 1956), (organized and edited by E. M. Crook), *review* by Dr. O. T. G. Jones, 968
Activity (Enzyme), in the 'Isolated' Colon (Dr. B. F. Martin), 1464
Activity (Fibrinolytic) : Salt Concentration and (Dr. Monamy Buckell and Margaret Truscott), 1268
Activity (Fungicidal) : A Bacterium with (W. E. Crawley and D. C. Dodd), 63
Activity (Glutaminase), of the Foetal Membranes and Kidneys of Pigs (Ingeborg C. Radde and Prof. R. A. McCance), 115
Activity (Histolytic), in Seasonal Hypertrophy of the Reproductive Organs of *Hyla aurea* (Prof. L. R. Richardson), 480
Activity (Hypotensive or Sedative) : Reserpine Derivatives with Specific (A. Garattini, A. Mortari, A. Valsecchi and L. Valzelli), 1273
Activity (Immunological), of Precolostral Calf Serum (J. L. Turk), 838
Activity (Intestinal Proteinase): Neurosecretion and, in an Insect *Calliphora erythrocephala* Meig. (Ellen Thomsen and Ib Møller), 1401
Activity (Leucine Aminopeptidase), in Mast Cells (Dr. I. Braun-Falco and Dr. K. Salfeld), 51
Activity (Lipase and Alkaline Phosphatase) : Histochemical Demonstration of, in the Fat Body of the Desert Locust (J. C. George and J. Eapen), 268
Activity (Liver Hexokinase), in Rats adapted to Intermittent Starvation (Dr. R. Petrásek), 329
Activity (Magnetic) : Effect of, on Drifts of the F2 Region (Prof. B. Ramachandra Rao, E. Bhagiratha Rao and Y. V. Ramana Murty), 667
Activity (Mutagenic), of the Alkaloid Heliotrine in *Drosophila* (Dr. A. M. Clark), 731
Activity (Nervous) : Neuronal Dye-Sorption as a Histochemical Indicator of (Prof. Roland Fischer and Prof. Wolfgang Zeman), 1337
Activity (Pancreatic), of Guinea Pigs : Effect of β-Hydroxybutyrate Injections on the (Dr. H. D. Brahmachari and Mahendra Kumar), 51
Activity (Prolonged Muscular), without Phosphate Exchange (Prof. Jacob Sacks), 825
Activity (Reduced), of Histaminase in Rats sensitized by *Bordetella pertussis* (Makoto Niwa, Yutaka Yamadeya, Toshitaka Matsui and Prof. Yoshio Kuwajima), 755 ; (Toshitaka Matsui, Masayoshi Kishigami and Prof. Yoshio Kuwajima), 756
Activity (Serum Transaminase) : Changes in, following Myocardial Damage due to Lymphatic Congestion (M. Földi, Dr. P. Braun, Dr. M. Papp and Dr. I. Horváth), 1333
Activity (Succinic Dehydrogenase), in Brain Tissue of Rats after Ovariectomy and Steroid Administration (H. Sobel and B. Eckstein), 54
Activity (Synthetic), of Polynucleotide Phosphorylase from Sperm (Prof. Anwar A. Hakim), 334
Activity (Transaminase), in Dogs' Serum and Lymph after Hepatic Damage due to Acute Biliary Obstruction : Determination of (Dr. P. Braun, Dr. M. Papp and Dr. I. Horváth), 48
Activity and Behaviour in a Group of Small Animals : A Photographic Method for recording (Dr. D. K. Edwards), 625
Actomyosin : Proton Transfer and Super-contraction in (Dr. F. G. E. Pautard), 1391
Acute Alcoholic Intoxication : Triiodothyronine in (Dr. Henry Newman and Marion Edmonds Smith), 689
Acute Biliary Obstruction : Determination of Transaminase Activity in Dogs' Serum and Lymph after Hepatic Damage due to (Dr. P. Braun, Dr. M. Papp and Dr. I. Horváth), 48
Acute Insulin Deficiency : Production of, by Administration of Insulin Antiserum (P. H. Wright), 829
Acute Radiation Syndrome in the Plaice : Leucocytosis in Response to Bacteraemia as a Feature of the (A. Preston), 832
Ada, G. L., and Anderson, S. G. : Yield of Infective 'Ribonucleic Acid' from Impure Murray Valley Encephalitis Virus after Different Treatments, 799
Ada, G. L., and French, E. L. : Purification of Bacterial Neuraminidase (Receptor-destroying Enzyme), 1740
Adam, Dr. K. R., and Weiss, Dr. C. : Distribution of 5-Hydroxytryptamine in Scorpion Venoms, 1398
Adams, Dr. Roger : Elected a member of the Council of the United States National Academy of Sciences, 1575
Adams, W. N., and others : Smoke Emission of Low-Temperature Chars, 33
Adamson, A. W. (Spees, S. T., and) : Co-ordination Chemistry (Mechanisms of the Photochemical Reactions of Complex Ions), 1784
Adaptation of Marine Bacteria to Growth in Media lacking Sodium Chloride (Prof. D. B. Pratt and G. Waddell), 1208
Adaptation of a Photometer for the Direct Recording of Column Chromatograms (Prof. M. Verzele), 604
Adaptation (Molecular), in Haemoglobins—Nature of the Bohr Effect (Austen Riggs), 1037
Adaptive Formation of Tryptophan Peroxidase : Prevention of, by a Carcinogenic Azo Dye (Dr. Silvio Fiala and Anna A. Fiala), 1532
Adaptive Synthesis of Nitrate Reductase in Higher Plants (Dr. E. J. Hewitt and M. M. R. K. Afridi), 57
Addison, C. C., and Logan, N. : Co-ordination Chemistry (Properties of Volatile Nitrato–Iron Complexes), 1785
Adélie Penguin : The, *Pygoscelis adeliae* (Hombron and Jacquinot), (Dr. William J. L. Sladen), 23
Adenosine Diphosphate : Interaction of Magnesium and, in Photosynthetic Phosphorylation (J. B. Mudd), 900
Adenovirus Antigens : Study of, by Immunoelectrophoresis (Dr. H. G. Pereira, Dr. A. C. Allison and Dr. C. P. Farthing), 895
Adenylosuccinic Acid : Synthesis of, in Preparations of Mammalian Skeletal Muscle (C. L. Davey), 995
Adhesion and Ion-Exchange between Mica Surfaces (George L. Gaines, jun.), 1109
Adjuvants (Growth), in Culture : Morphogenetic Response of *Citrus* Ovules to (N. S. Ranga Swamy), 735
Administered Vitamin B_{12} (Orally) : Effect of D-Sorbitol on the Absorption of (Dr. J. N. Marshall Chalmers and N. K. Shinton), 120
Administration of Insulin Antiserum : Production of Acute Insulin Deficiency by (P. H. Wright), 829
Administration (*in vivo*) of 5-Iododeoxyuridine labelled with Iodine-131 : Incorporation of 5-Iodouracil labelled with Iodine-131 into the Deoxyribonucleic Acid of Human Leukaemic Leucocytes following (Dr. M. L. Eidinoff, L. Cheong, E. Gambetta Gurpide, R. S. Benua and R. R. Ellison), 1686
Administration (Oral) : Presence of Griseofulvin in Hair of Guinea Pigs after (J. C. Gentles, M. J. Barnes and K. H. Fantes), 256
Administrative Medicine—Transactions of the Fifth Conference, Princeton, 1956 (edited by George S. Stevenson), *review* by Dr. G. A. Clark, 639
Admission of Students to Universities, 1723
Adrenal Cortical Function in the Pregnant Sheep (Kathleen W. Robinson), 690
Adrenal Gland of Young Calves : Changes in the Secretion of 20α-Hydroxypregn-4-en-3-one by the (Dr. W. E. Balfour, Dr. R. S. Comline and R. V. Short), 467
Adrenal Glomerulosa : Stress Activation of (Dr. M. Hill, K. Dvořák and M. Pospíšil), 1819
Adrenal 17-Hydroxycorticosteroid Secretion in the Dog : Effect of Morphine upon the (Prof. Tatuzi Suzuki, Kazukuni Yamashita, Seiichi Zinnouchi and Takaaki Mitamura), 825
Adrenal Medulla : Deoxyribonucleic Acid Content of the Cell-Nuclei in the, after Exposure to Low Temperatures (L. Leeman), 1188
Adrenaline : Condensation Products of Ethylenediamine with (Dr. Kunio Yagi and Dr. Toshiharu Nagatsu), 822
  Rumination in Sheep caused by Injection of (R. N. B. Kay), 552
Adrian, Rt. Hon. Lord : The Place of Science in Universities Past and Present, 1706

INDEX

Adsorption and Desorption of Moisture in Fired Ceramic Materials (F. Vaughan and A. Dinsdale), 600
Adult Education : Developments in, *review* by T. H. Hawkins, 1419
Adult Education (English) : Trends in (edited by Prof. S. G. Raybould), *review* by T. H. Hawkins, 1419
Adult Human Haemoglobin : Comparison of Normal, with Haemoglobin I by 'Fingerprinting' (Constituents of Human Haemoglobin), (Makio Murayama and Dr. V. M. Ingram), 1798
Adult Mosquitoes : Galeal Structure in (Gordon Surtees), 971
Adult Rabbits : Serum Antibody and γ-Globulin in Baby Rabbits after Transfer of Ribonucleoprotein from (Dr. Miroslava Hrubešova, Dr. Brigitte A. Askonas and Dr. J. H. Humphrey), 97
Adult and Foetal Human Haemoglobins : Identity of the α-Chains of (J. A. Hunt), 1373
Adults (Male and Female), of *Trogoderma granarium* Everts : Differential Response of, towards Sterilizing Doses of Gamma-radiation (G. C. Carney), 338
Advance Detonation in a Tubular Charge of Explosive (Dr. D. W. Woodhead), 1756
Advanced European Research (Council of Europe Competition in), 509
Advanced Gas-cooled Reactor Power Stations, 508
Advanced Study in Science (NATO support for Institutes for), 509
Advancement (Educational), and the Under-developed Countries, 633
Advances in Clinical Chemistry (edited by Dr. Harry Sobotka and Dr. C. P. Stewart), Vol. 1, *review* by Prof. J. N. Davidson, 5
Advances in Enzymology : Further, *review* by Dr. Edwin C. Webb, 961
Advances in Enzymology and related Subjects of Biochemistry (edited by F. F. Nord), Vol. 20, *review* by Dr. Edwin C. Webb, 961
Advances in Food Research (edited by E. M. Mrak and G. F. Stewart), Vol. 8, *review* by Dr. Magnus Pyke, 351
Advances in Microbiology, *review*, 1219
Advances in Protein Chemistry (edited by C. B. Anfinsen, Jr., M. L. Anson, Kenneth Bailey and John T. Edsall), Vol. 12, *review* by Dr. M. F. Perutz, 1290
Advances in Protein Chemistry : Recent (Department of Chemistry, Biology and Geology of the Kingston Technical College Postgraduate Lecture Course on), 86
Advances in Veterinary Science (edited by C. A. Brandly and E. L. Jungherr), Vol. 4, *review* by Prof. H. Burrow, 1555
Advances in Virus Research (edited by Kenneth M. Smith and Max A. Lauffer), Vol. 5, *review* by Prof. F. C. Bawden, 636
Adventitious Roots (Seminal and) : A Method of Growing Grass Plants with Separation of (R. Dorrington Williams), 415
Advisory Committee on Defence Science, Commonwealth—Meeting in in Australia (Sir Leslie Martin), 1165
Advisory Council on Scientific Policy : Eleventh Annual Report (1957-58), 67
Advisory Water Committee, Central : Fourth Meeting, 152
  Appointment of Prof. J. Proudman as chairman of the Sub-Committee on the Demand for Water, 152
Aerobacter aerogenes : Aerobic Fermentation of Whey by a Nitrogen-fixing Strain of (Prof. D. B. Johnstone and M. Pfeffer), 992
Aerobic Fermentation of Whey by a Nitrogen-fixing Strain of *Aerobacter aerogenes* (Prof. D. B. Johnstone and M. Pfeffer), 992
Aeronautical Establishment, National : Formation of, as a new Division of the National Research Council of Canada, 291
  Appointment of Frank R. Thurston as acting director, 291
Aeronautical Sciences, American Institute of : Election of Sir George R. Edwards as an Honorary Fellow, 368
  Election of Dr. A. M. Ballantyne as a Fellow, 368
Aeronautical Society, Royal : Honorary Companionship conferred on Gustavus Green, 154
  Gold Medal awarded to Marcel Dassault, 794
  Discussion on Hypersonic Flow, 1095
  Lecture Theatre for the, 1569
  Honorary Fellowship conferred on Prof. J. Ackeret, Sir William S. Farren and S. B. Gates, 1648
  Honorary Companionship conferred on E. C. Bowyer and Sir William Hildred, 1648
  Silver Medal awarded to Dr. E. A. Watson, 1648
  Bronze Medal awarded to D. G. King-Hele, 1648
  British Gold Medal for Aeronautics awarded to R. S. Stafford, 1648
  British Silver Medal for Aeronautics awarded to D. J. Farrar and Dr. N. H. Searby, 1648
  Wakefield Gold Medal awarded to K. A. Wood, 1648
  R. P. Alston Medal awarded to A. W. Bedford, 1648
  N. E. Rowe Medal awarded to J. Dunham, 1648
  Simms Gold Medal awarded to R. P. Probert, 1648
  George Taylor (of Australia) Gold Medal awarded to H. L. Cox, 1648
  Edward Busk Memorial Prize awarded to T. R. F. Nonweiler, 1648
  Orville Wright Prize awarded to D. A. Spence, 1649
  Herbert Ackroyd Stuart Memorial Prize awarded to A. A. Lombard, 1649
  J. E. Hodgson Prize awarded to J. E. Allen, 1649
  Branch Prize awarded to B. D. Blackwell, 1649
  Navigation Prize awarded to C. M. Cade, 1649
  Usborne Memorial Prize awarded to Dr. J. S. Przemieniecki, 1649
  Pilcher Memorial Prize awarded to A. W. Kitchenside, 1649
Affinities : Atomic Electron (H. R. Johnson and Dr. F. Rohrlich), 244
Affinity (Electron), of Atomic Lithium (E. Holøien), 173
Affinity (Electron), of Oxygen (B. A. Tozer), 1389
Affonso, Ottilia R. (Mitidieri, Emilio, and) : Effect of Salicylate on Blood and Liver Xanthine Dehydrogenase of Rats, 471
Africa South of the Sahara, Commission for Technical Co-operation in (Food and Agriculture Organization of the United Nations and the) : Technical Meeting on Legumes in Agriculture and Human Nutrition, 439
Africa South of the Sahara, Scientific Council for : Publication No. 32, Ninth Meeting of the Scientific Council, Accra (1958), 585
Africa (Central) : Scientific Research in, 1718
Africa (East) : A Study of the Aphididae (Homoptera) of (V. F. Eastop), *review* by Dr. W. J. Hall, 208
Africa (East) High Commission : Annual Report for 1958, 1781
  Annual Report for 1957-1958 of the East African Industrial Research Organization, 1789
Africa (South) : Academic Freedom and the Universities of, 1551
Africa (West) : Flora of, *review* by A. W. Exell, 6
  A Third Species of 'Pepper' in (J. Yanney Wilson), 1142
Africa (West Tropical) : Flora of (Dr. J. Hutchinson and Dr. J. M. Dalziel), second edition revised by R. W. J. Keay, *review* by A. W. Exell, 6
Africa and England : Precambrian Coelenterata from Australia, (Dr. M. F. Glaessner), 1472
African Agriculture : Legumes in (Dr. R. O. Whyte and T. R. G. Moir), 439
African Aphids, *review* by Dr. W. J. Hall, 208
African Segmentary Systems : Tribes without Rulers—Studies in (edited by John Middleton and the late David Tait), *review* by Prof. M. Fortes, 1006
African (British East) Waters : Marlins in (F. Williams), 762
African (East) Industrial Research Organization : Annual Report for 1957-1958 (East Africa High Commission), 1789
African (South) Council for Scientific and Industrial Research (Dr. S. M. Naudé), 853
African (South) Council for Scientific and Industrial Research : Register of Current Scientific Research at South African Universities (1957), 366
  Report of the Symposium on Design for Tropical Living (prepared by the National Building Research Institute), 1022
African (South) Museum : Report for 1957-58, 1570
African (South) Stone Age Cultures : Some (Dr. R. J. Mason), 377
African (South) Universities : Register of Current Scientific Research at, 1957 (South African Council for Scientific and Industrial Research), 366
Afridi, M. M. R. K. (Hewitt, Dr. E. J., and) : Adaptive Synthesis of Nitrate Reductase in Higher Plants, 57
Afrique Centrale, Institut pour le Recherche Scientifiques en : Annual Report for 1956, 1718
After-Effects : Figural (Dr. Peter McEwen), 1027
Agar (Kligler's Iron) : The Phenylalanine Test on, for the Identification of *Proteus* (D. J. Stewart), 1537
Agar Diffusion Plates : Photographic Recording of (J. R. Hunter), 1283
AGARD : AGARDograph No. 29, Polar Atmosphere Symposium, Oslo, 1956, Part 1, Meteorology Section (edited by R. C. Sutcliffe) ; Part 2, Ionospheric Section (edited by K. Weekes), *review* by James Paton, 279
  Joint Meeting of the Aeromedical and Flight Test Techniques and Instrumentation Panels, 652
  AGARDograph No. 25 : Aviation Medicine—Selected Reviews (edited by Clayton S. White, W. Randolph Lovelace, II, and Frederic G. Hirsch), *review*, 1291
Agaricus campestris L. ex Fr. : Spore Germination in (Dr. D. M. McTeague, Dr. S. A. Hutchinson and Dr. R. I. Reed), 1736
Age : Variation of Sensitivity to Ionizing Radiation with (M. L. Crosfill, Patricia J. Lindop and Prof. J. Rotblat), 1729
Age of the Earliest Remains of Man, 1433
Age of Plants : Amino-Acid Composition of the Proteins of Barley Leaves in relation to the Mineral Nutrition and (Dr. B. P. Pleshkov and Dr. L. Fowden), 1445
Age of Science : Education in the, 1436
Age and Sex : Water and Electrolyte Metabolism in relation to Age (Ciba Foundation Colloquia on Ageing, Vol. 4), (edited by G. E. W. Wolstenholme and Maeve O'Connor), *review* by Prof. P. L. Krohn, 777
Age (Boreal) : A Marine Transgression of, in the Southernmost Part of Norway (Gunnary Gabrielsen), 1616
Age (Bronze) : Life and Death in the (Sir Cyril Fox), *review* by M. C. Burkitt, 1486
Age (Known) : Radiocarbon Measurements on Samples of (W. S. Broecker, Edwin A. Olson and Junius Bird), 1582
Ageing : Ciba Colloquia on, Vol. 4, Water and Electrolyte Metabolism in relation to Age and Sex (edited by G. E. W. Wolstenholme and Maeve O'Connor), *review* by Prof. P. L. Krohn, 777
Ageing of Human Cartilage (David Kaplan and Dr. Karl Meyer), 1267
Ageing Periosteum : Changes in the Osteoblastic and Mitochondrial Population of (Dr. E. A. Tonna and Dr. N. Pillsbury), 337
Ageing Process in the Ovary : Influence of the Anterior Pituitary on the (Dr. E. C. Jones and Prof. P. L. Krohn), 1155
Ageing Rats : Sex Incidence of Vascular Lesions in, in relation to Previous Pregnancies (Prof. Theodore Gillman and Michael Hathorn), 1139
Agent (Protective), against Osmotic Lysis : Spermine as a (J. Mager), 1827
Agents : Effects of 2:4-Dinitrophenol and other, on the Swelling of Isolated Mitochondria (Dr. J. B. Chappell and Dr. G. D. Greville), 1737
Agents (Physical) : Method for Testing the Influence of Drugs and upon Mitosis (Prof. Elio Guido Rondanelli, Pasquale Gorini and Demenico Pecorari), 190
Ager, Dr. J. A. M., and others : New Variant of Human Foetal Haemoglobin, 31
Ages : Frequency of Meteorite Falls throughout the (Prof. Hans Pettersson), 1114 ; (Dr. J. F. Lovering), 1664
Ages (Cosmic-Ray Exposure), of Meteorites : Calculation of Erosion in Space from the (Dr. F. L. Whipple and Dr. E. L. Fireman), 1315
Aggregation of Cod Myosin during Frozen Storage (J. J. Connell), 664
Agnostids : General Caeca of (A. A. Öpik), 1750
Agranoff, Dr. B. W., and Fox, M. R. Spivey : Antagonism of Choline and Inositol, 1259
Agricultural Advisory Service, National ; Retirement of Sir Robert Rae from the directorship, 1160
  Appointment of J. A. McMillan as director, 1160
  Appointment of W. E. Jones as senior education and advisory officer, 1160
  Appointment of H. E. Evans as director of the National Agricultural Advisory Service in Wales, 1160
Agricultural Aviation, Vol. 1, No. 1 (European Agricultural Aviation Centre), 720
Agricultural Geography : Ecology and Economics of, *review* by Prof. A. N. Duckham, 423
Agricultural History Society (British), and the Economic History Society : Joint Conference on Agriculture and Rural Life, 582
Agricultural Research : Studentships and Fellowships in (Agricultural Research Council), 722
Agricultural Research Council : Grant of £1,492 to the Department of Veterinary Medicine in the University of Bristol, for research on experimental transmissions of lymphoid leukosis, 581

  Grant of £1,172 to the Department of Physiology in the University of Bristol, for research on bovine acetonaemia, 581
  Studentships and Fellowships in 1959, 722
  To take over the Ditton Laboratory, the Low Temperature Research Station and the Pest Infestation Laboratory of the Department of Scientific and Industrial Research, 862
  Investigation into the Quality of Protein Feeding-Stuffs, 1303
Agricultural Research Institute, Indian (Dr. B. P. Pal), 371
Agricultural University, Wageningen (under the auspices of the Comité Européen de Zoologie Agricole and the) : Proceedings of a Symposium on Insect and Food-plant (Wageningen, 1957), *review* by Dr. C. J. Banks, 1767
Agricultural and Horticultural Research Station (the National Fruit and Cider Institute), Long Ashton, Bristol : Annual Report for 1957, with Index 1953-57, 1507
Agriculture at Aberdeen, 862
Agriculture : American (Prof. Edward Higbee), *review* by Prof. A. N. Duckham, 423
  Inorganic Micronutrients in Physiology and, *review* by Dr. E. J. Hewitt, 1009
Agriculture, Canadian Department of : Ninth International Botanical Congress, 1502
Agriculture (African) : Legumes in (Dr. R. O. Whyte and T. R. G. Moir), 439
Agriculture (Tropical) : An Introduction to (Sir Harold Tempany and D. H. Grist), *review* by Prof. J. W. Purseglove, 966
Agriculture, Fisheries and Food, Ministry of : Fishery Investigations, Ser. 2, Vol. 22, No. 4, Feeding of the Oystercatcher (*Haematopus ostralegus*) on the Edible Mussel (*Mytilus edulis*) in the Estuary of the River Conway (R. E. Drinnan), 153
  Appointment of Prof. A. N. Duckham as chairman of the Milk and Milk Products Technical Advisory Committee, 368
  Fishery Investigations, Ser. 2, Vol. 21, No. 8, An Account of the Fishing Gear of England and Wales (the late F. M. Davis), revised edition, 1023
  Fishery Investigations, Ser. 2, Vol. 21, No. 6, The Bear Island Cod—Migrations and Movements (G. C. Trout), 1100
  Appointment of Dr. H. A. Cole as director of fisheries research, 1567
  Appointment of R. J. H. Beverton as deputy director of fisheries research, 1568
Agriculture, Fisheries and Food, Ministry of, and the Scottish Home Department (Development Commissioners, in association with the) : Postgraduate Training Grants in Fishery Research, 1094
Agriculture and Human Nutrition : Legumes in (Food and Agriculture Organization of the United Nations and the Commission for Technical Co-operation in Africa South of the Sahara Technical Meeting on), 439
Agriculture and Rural Life (British Agricultural History Society and the Economic History Society Joint Conference on), 582
Aharoni, Yohanan, and others : Hazor I, an Account of the First Season of Excavations, 1955 (The James A. De Rothschild Expedition at Hazor), *review* by Peter J. Parr, 951
Ahmed, A. K. Shamsuddin, and Wilkins, R. G. : Co-ordination Chemistry (Kinetics of the Dissociation of Complex Cyanides and of Ethylene–Diamine Nickel Complexes), 1784
Ahrenfeldt, Dr. Robert H. : Psychiatry in the British Army in the Second World War, *review* by Dr. D. Russell Davis, 208
Ahuja, L. D. : The Nature of Coal (Conversion of Non-coking Coal to Coking Coal by Partial Hydrogenation), 1438
Aimen, R. A. (Bhide, Dr. N. K., and) : Pharmacology of a Tranquillizing Principle in *Paspalum scrobiculatum* Grain, 1735
Aims of Education (A. N. Whitehead), 1437
Air : Effect of Humidity on the Breakdown of a 1-cm. Homogeneous Field Spark Gap in (Dr. K. Phillips, K. R. Allen and A. Refsum), 532
Air (Humid) : Secondary Ionization in (Prof. J. M. Meek), 1805
Air Force, United States Department of the (sponsored by the) : Guided Missiles—Operations, Design and Theory, *review*, 210
Air Force Cambridge Research Center (United States) : Conference on Silicon Carbide, 722
Air Force Office of Scientific Research : Grant of 38,415 dollars to Prof. G. A. Jeffrey (University of Pittsburgh), to initiate research on the structure of crystalline hydrates of organic molecules and ions, 86
Air Force Office of Scientific Research, and others : International Seminar on the Atomic Mechanisms of Fracture, 154
Air Ions (Negative) : An Ezymatic Basis for the Acceleration of Ciliary Activity by (Prof. A. P. Krueger and Richard F. Smith), 1332
Air Ministry (Meteorological Office) : Geophysical Memoir No. 101, Upper Air Temperature over the World (N. Goldie, J. G. Moore and E. E. Austin), 864
Air Pollution Control Association : Annual Meeting, 722
Air Shower Particles : Multiple Geiger Counter Telescope Measurements of the Directions of (Dr. H. D. Rathgeber), 386
Air Showers : Extensive (Dr. William Galbraith), *review* by Dr. R. M. Tennent, 1555
Air Temperature Record : World Low, 153
Air Temperature (Upper) over the World (N. Goldie, J. G. Moore and E. E. Austin), 864
Airborne Bacteria : Chloramphenicol and Survival of (S. J. Webb), 1072
Airborne Droplets : Detecting Volatile (K. R. May), 742
Airborne Radar at the Royal Radar Establishment, 647
Aircraft : Navigational Aids for, 1019
Aircraft (Historic) : Register of, 580
Aircraft (Low-flying) : Drift of Toxic Chemicals released from a (D. Yeo, N. B. Akesson and H. H. Coutts), 131
Aircraft Establishment, Royal : Appointment of S. F. Follett as deputy director (equipment), 931
  Appointment of Dr. A. G. Touch as senior superintendent of the Radio Department, 931
  Appointment of R. J. Lees as head of the Instrument and Photographic Department, 931
  Table of Artificial Earth Satellites, 1566
Airglow (Twilight), in the Northern Hemisphere : Observations of the Lithium Lines in the (Prof. A. Vallance Jones), 1315
Airglow at 6708 A. (New Twilight) : Origin of Upper-Atmosphere Lithium Atoms responsible for the (D. R. Barber), 384
Aked, A., and others : Gas Discharges (Spark, High-frequency and Glow Discharges), 93
Akesson, N.B., and others : Drift of Toxic Chemicals released from a Low-flying Aircraft, 131
Alaska : Urinary Excretion of β-Amino-isobutyric Acid in Eskimo and Indian Populations of (Dr. A. C. Allison, Dr. B. S. Blumberg and Dr. S. M. Gartler), 118
Albasiny, E. L. : The Preparation of Programs for an Electronic Digital Computer, *review*, 969
Albers, Dr. Wayne, and others : Effects of Pyridoxine Withdrawal on Cerebral Circulation and Metabolism in a Pyridoxine-dependent Child, 751
Albertsson, Dr. P. Å. (Frick, Dr. G., and) : Bacteriophage Enrichment in a Liquid Two-Phase System with Subsequent Treatment with 'Freon' 113, 1070
Albino Citrus Seedlings : Inducing Chlorophyll Formation in (Dr. Faisal A. Minessy), 553
Albino Specimen of the Common Frog (G. E. Williams), 1408
Albino and Pigmented Mice receiving Furocoumarins—Psoralen and 8-Methoxypsoralen : Ultra-violet Carcinogenesis in (M. A. Pathak, Prof. F. Daniels, jun., C. E. Hopkins and T. B. Fitzpatrick), 728
Albrecht, K. (Wix, Dr. G., and) : A New Method for the Microbiological Oxidation of Steroids, 1279
Albugo candida : Oospore Germination in (T. C. Vanterpool), 1718
Albumin labelled with Iodine-131 in an Analbuminaemic Subject (T. Freeman, C. M. E. Matthews, Dr. A. S. McFarlane, H. Bennhold and E. Kallee), 606
Albumin in the Plasma of Thyrotoxic Patients : An Iodine Compound associated with (Christina Cameron and K. Fletcher), 116
Albumin (Human), labelled with Iodine-131 : Chromatographic Behaviour of (Dr. S. Cohen), 393
Albumin (Serum), during Short-term Action of Pepsin at Room Temperature : Splitting of the Electrophoretic Pattern of (E. Annau), 190
Alcohol : Utilization of, in Germinating Pea Seedlings (E. A. Cossins and Dr. E. R. Turner), 1599
Alcohol (Allyl), as a Nutrient for Micro-organisms (H. L. Jensen), 903
Alcohol (Cyclic Allylic) : Effect of Alkali Salts on the Steric Course of Hydrogenation of a (M. C. Dart and Prof. H. B. Henbest), 817
Alcoholic Intoxication (Acute) : Triiodothyronine in (Dr. Henry Newman and Marion Edmonds Smith), 689
Alcohols : Effect of Low Concentrations of, on the Interfacial Tension between Water and Hydrocarbons (F. Franks and Dr. D. J. G. Ives), 316
Alderson, R. H. (Wroe, H., and) : An Effect of Oxide Layers on the Behaviour of Vacuum Arc Cathode Spots, 1544
Aldosaccharides in Body Fluids : Rapid Specific Method for Determination of (Dr. Eric Hultman), 108
2-Aldoxime (Pyridine) : Ferrous and Ferric Complexes with (Dr. G. I. H. Hanania and Dr. D. H. Irvine), 40
Alexander, J. B. : Geology and Palaeontology in Malaya—Pre-Tertiary Stratigraphic Succession in Malaya, 230
Alexander, Dr. K. M. : Errors caused by Partial Drying of Hardened Portland Cement during Testing, 885
Alfvén Waves in a Gas Discharge (D. F. Jephcott), 1652
Alga (Marine Red), requiring Vitamin B_{12} : *Goniotrichum elegans*, a (Lisbeth Fries), 558
Algal Species (Epiphytic), and their Macrophytic Hosts : Relationship between (G. A. Prowse), 1204
Alicyclic Structures in Coals (S. Ergun and V. H. Tiensuu), 1668
Alicyclicity and Smoke Emission of Coal (B. K. Mazumdar, S. S. Choudhury and A. Lahiri), 1613
Alimen, H., et autres : Archives de l'Institut de Paléontologie Humaine, Mémoire 29, La Grotte de Fontéchevade, Troisiéme partie, Géologie et Paléontologie, 1369
Aliphatic Fluorine Compounds (A. M. Lovelace, Douglas A. Rausch and William Postelnek), *review* by Prof. R. N. Haszeldine, 139
Alivisatos, Prof. Spyridon G. A. : Mechanism of Action of Diphosphopyridine Nucleotidases, 1034
Alkali Cations : Absorption of, by Plant Tissue Cultures (Dr. J. F. Sutcliffe and E. R. Counter), 1513
Alkali Concentration (Low) : Catalytic Action of Copper in the Alkaline Autoxidation of Cellulose at (R.I.C. Michie and Dr. S. M. Neale), 534
Alkali Fluorides : Bond Energies of some (Dr. F. M. Page and Dr. T. M. Sugden), 1672
Alkali Salts : Effect of, on the Steric Course of Hydrogenation of a Cyclic Allylic Alcohol (M. C. Dart and Prof. H. B. Henbest), 817
Alkaline Autoxidation of Cellulose at Low Alkali Concentration : Catalytic Action of Copper in the (R. I. C. Michie and Dr. S. M. Neale), 534
Alkaline Phosphatase : Distribution of, in the Arteries of several Species (Dr. Manuel René Malinow, Martha A. Fernandez, Alvaro L. Gimeno and Grato E. Bur), 1262
Alkaline Phosphatase Activity (Lipase and) ; Histochemical Demonstration of, in the Fat Body of the Desert Locust (J. C. George and J. Eapen), 268
Alkaline Phosphomonoesterase in *Escherichia coli* : A Possible Negative Feedback Phenomenon controlling Formation of (T. Horiuchi, S. Horiuchi, and D. Mizuno), 1529
Alkaloid Heliotrine in *Drosophila* : Mutagenic Activity of the (Dr. A. M. Clark), 731
Alkaloids (Pyrrolizidine) : Action of, on the Neuro-Muscular Junction (Dr. C. H. Gallagher and Dr. J. H. Koch), 1124
Alkyl N-(*bis*-(ethylenimido)phosophoro)-carbamates, a New Series of Anti-Tumour Agents : 'Dual Antagonists'—(Thomas J. Bardos, Zinon B. Paranastassiou, Albert Segaloff and Julian L. Ambrus), 399
Alkyl-Aryl Sodium Sulphonates as Standard Substances in Detergent Chemistry : Some (E. Q. Laws and W. Hancock), 1473
All : Secondary Education for—a New Drive (White Paper on), 511
All-India Congress of Zoology : First (Zoological Society of India), 1304
Allan, D. : Appointed lecturer in applied veterinary pathology at the University of Liverpool, 581
Allard Lake Ilmenites : Remanent Magnetism of the (Charles M. Carmichael), 1239
Allchin, Dr. F. R. : Morhana Parar, 437
  An Indian History of Science, *review*, 1353
Allen, Dr. Ann, and Alston, Dr. R. E. : Formation of Purple Pigment in *Spirogyra pratensis* Cultures, 1064

Allen, Prof. A. J. : Awarded a grant of 129,000 dollars by the Office of Naval Research, to continue research on precision scattering of nuclear particles, 86
Allen, Dr. Clifford : Social Class and Mental Illness, *review*, 354
Allen, Frank W., and others (edited by): Annual Review of Biochemistry, Vol. 27, *review* by Prof. F. G. Young, 961
Allen, Dr. G. : Relaxation Processes (Measurements on Mechanical Relaxation of Rubber), 584
Allen, Prof. Jack : *Obituary* of Prof. A. H. Gibson, 859
Allen, J. E. : Awarded the J. E. Hodgson Prize of the Royal Aeronautical Society, 1649
Allen, Prof. James S. : The Neutrino, *review* by Prof. H. W. B. Skinner, 1421
Allen, K. R., and Phillips, Dr. K. : Effect of Humidity on the Spark Breakdown Voltage, 174
  Effect of Radiation on the Breakdown of Homogeneous Field and Sphere Gaps, 233
Allen, K. R., and others : Effect of Humidity on the Breakdown of a 1-cm. Homogeneous Field Spark Gap in Air, 532
Allen, Dr. N. L., and Payne, Dr. R. M. : Gas Discharges (Operation of SCEPTRE III in the Laboratories of Associated Electrical Industries), 92
Allergic Disorders : Immunological Aspects of (British Society for Immunology and the British Association of Allergists Symposium on), 296
Allergists, British Association of (British Society for Immunology and the) : Symposium on the Immunological Aspects of Allergic Disorders, 296
Allibone, Dr. T. E. : Fusion of Heavy Hydrogen, 569
Allison, Dr. A. C. : Genetic Control of Human Haptoglobin Synthesis, 1312
Allison, Dr. A. C., and Humphrey, Dr. J. H. : Estimation of the Size of Antigens by Gel Diffusion Methods, 1590
Allison, Dr. A. C., and others : Urinary Excretion of β-Amino-*iso*butyric Acid in Eskimo and Indian Populations of Alaska, 118
  Study of Adenovirus Antigens by Immunoelectrophoresis, 895
Alloxanized Rats (Normal and) : Action of Nicotinamide on Acetoacetate Metabolism of Liver Homogenates of (S. Eser, S. Tekman and A. Araz), 184
Alloys : Precipitation in (X-Ray Diffraction and Electron Microscopy Groups of the Institute of Physics Conference on), 796
Alloys (Aluminium–Zinc) : Crystallographic Orientation of Nodules formed by the Grain Boundary Reaction of (Dr. Ryoji Watanabe and Dr. Shigeyasu Koda), 1667
Alloys (Chromium–Iron and Chromium–Manganese) : Low-temperature Specific Heats of Body-centred Cubic (C. T. Wei, C. H. Cheng and Prof. P. A. Beck), 315
Alloys (Ternary Aluminium–Zinc–Magnesium) : Fatigue Properties of (I. J. Polmear), 1388
Allport, Noel L., and Keyser, Dr. J. W. : Colorimetric Analysis, Vol. I, Determinations of Clinical and Biochemical Significance, second edition, *review* by Dr. N. R. Lawrie, 207
Allsopp, Dr. A. (Mitra, Dr. G. C., and) : Effects of Kinetin, Gibberellic Acid and certain Auxins on the Development of Shoot Buds on the Protonema of *Pohlia nutans*, 974
Allt Rhyd-y-groes Nature Reserve (Nature Conservancy), 1650
Allyl Alcohol as a Nutrient for Micro-organisms (H. L. Jensen), 903
Allylic Alcohol (Cyclic) : Effect of Alkali Salts on the Steric Course of Hydrogenation of a (M. C. Dart and Prof. H. B. Henbest), 817
Alper, Tikvah (Gillies, Dr. N. E., and) : Reduction in the Lethal Effects of Radiations on *Escherichia coli B* by Treatment with Chloramphenicol, 237
α-Chains of Adult and Foetal Human Haemoglobins : Identity of the (J. A. Hunt), 1373
α-Globulin Fraction in Human Serum : Prealbumin as a Complex in the (Dr. J. R. Tata), 877
α-Glycerophosphate Dehydrogenase : Anion Inhibition of (Dr. Otto Z. Sellinger and Dr. O. Neal Miller), 889
α-Helices and a New Polypeptide Fold in Poly-β-Benzyl-L-Aspartate (E. M. Bradbury, L. Brown, A. R. Downie, Dr. A. Elliott, W. E. Hanby and T. R. R. McDonald), 1736
α-Keratin : Structure of (Dr. R. D. B. Fraser, T. P. Macrae and Dr. G. E. Rogers), 592
α-Tocopherol and Hyaluronidase *in vivo* (Mrs. Elizabeth A. Irving), 398
α-, β-, γ- and δ-Tocopherols (Pure), in the Growing Chick : Relative Rates of Liver Storage of (T. W. Griffiths), 1061
Alsop, L. E., and others : Maser Observations in Radio Astronomy, 223
Alstead, Dr. S. : Elected a Fellow of the Royal Society of Edinburgh, 719
Alston, Dr. R. E. (Allen, Dr. Ann, and) : Formation of Purple Pigment in *Spirogyra pratensis* Cultures, 1064
Alston (R. P.) Medal of the Royal Aeronautical Society awarded to A. W. Bedford, 1648
Alt, J. : Antarctic Meteorology, 1504
Altenburg, Edgar (Altenburg, L. S., and) : Ratio of Visible to Lethal Mutations produced in *Drosophila* by Phenylalanine Mustard, 699
Altenburg, L. S., and Altenburg, Edgar : Ratio of Visible to Lethal Mutations produced in *Drosophila* by Phenylalanine Mustard, 699
Alteration in the Excretion of Free Serine in Urine from Irradiated Humans (Dr. Arthur L. Kretchmar), 1809
Alterations (Geotropic and Morphological), in Rice Seedlings caused by Plant Growth Regulators (E. H. Roberts), 1197
Alternating-Current Voltammetry (Cyclic), with a Platinum Electrode (André L. Juliard), 1040
Alternsforschung : Experimentelle—Symposium der Europäischen Abteilung des Biologischen und Medizinischen Forschungskomitees der Internationalen Gerontologischen Gesellschaft, Basel, 1956 (herausgegeben von F. Verzár), *review* by Prof. P. L. Krohn, 777
Altitude (50 km.) : Observations of Intense Ionization of Long Duration below, after some Strong Solar Flares (Dr. Bengt Hultqvist and Johannes Ortner), 1179
Altitude (High-) Explosions : Geophysical Effects associated with (Dr. P. J. Kellogg, Prof. E. P. Ney and Prof. J. R. Winckler), 358
Altitude (High-) Geophysical Experiments : Argus (Dr. Alan T. Waterman and Dr. Detlev W. Bronk), 1019
Altitude (High-) Nuclear Explosions : Geophysical Effects of (T. Obayashi, S. C. Coroniti and E. T. Pierce), 1476
Altschul, Aaron M. (edited by) : Processed Plant Protein Foodstuffs, *review* by Dr. Magnus Pyke, 351
Altschul, Lucille (Cohen, Prof. Saul G., and) : Asymmetric Hydrolysis of Diethyl Acetamidomalonate by Chymotrypsin, 1678
Altschul, Prof. Rudolf : *Obituary* of Prof. Alfred Kohn, 1229
Altszuler, N., and others : Mechanism of Action of Insulin, 1123
Alumina : Polymorphic Conversion of Mercuric Iodide on (Prof. Harry Zeitlin and Harry Goya), 1041
γ-Alumina (Anhydrous) : Evidence for a Variable Long-range Order in nearly (Prof. G. W. Brindley and Dr. M. Nakahira), 1620
Aluminium Hydroxides derived from Proton Magnetic Resonance : Positions of Protons in (Structures of some Hydroxides and Hydrous Oxides), (D. J. Kroon and C. v. d. Stolpe), 944
Aluminium Laboratories, Ltd. : Appointment of Dr. Robert T. Parker as head of the Banbury and Geneva offices, 1502
Aluminium Oxide Anodic Films : Sealing of (Dr. R. M. Hinde, E. A. Kellett and P. H. Harris), 39
γ-Aluminium Oxide/Platinum : Structure and Mode of Action of the Contact (Prof. Alfons Krause), 1615
AlO Spectrum : Hollow-Cathode Emission of the (V. Wilson Goodlett and K. Keith Innes), 243
Aluminium–Zinc Alloys : Crystallographic Orientation of Nodules formed by the Grain Boundary Reaction of (Dr. Ryoji Watanabe and Dr. Shigeyasu Koda), 1667
Aluminium–Zinc–Magnesium Alloys (Ternary): Fatigue Properties of (I. J. Polmear), 1388
Aly, Raga H. (Gabr, Dr. Yousry, and) : Slow Contraction of Smooth Muscle produced by Human Plasma, 897
Amarose, A. P. : Some Effects of Colchicine on Lampbrush Chromosomes, 975
Ambrus, Julian L., and others : 'Dual Antagonists' ; Alkyl N-(*bis*-(ethylenimido) phosphoro)-carbamates ; a New Series of Anti-Tumour Agents, 399
  Anti-Tumour Activity of 5-Mercaptouracil, 612
Ameen, A., and Shafiq, Dr. S. A. : Proepithelial Regeneration in the Midgut of Beetles, 913
America : John and William Bartram's (edited by Helen Gere Cruickshank), *review* by Dr. L. Harrison Matthews, 1006
America North of Mexico : The Spider Family Dictynidae in (Prof. Ralph V. Chamberlin and Willis J. Gertsch), 1170
American Academy of Arts and Sciences : Rumford Premium for 1959 awarded to Prof. George Wald, 435
American Agriculture (Prof. Edward Higbee), *review* by Prof. A. N. Duckham, 423
American Arachnida (Theodore Savory), 1170
American Association for the Advancement of Science, and others : International Oceanographic Congress, 1093, 1502
American Chemical Society : Monograph Series No. 138, Aliphatic Fluorine Compounds (A. M. Lovelace, Douglas A. Rausch and William Postelnek), *review* by Prof. R. N. Haszeldine, 139
  1958 Pittsburgh Award of the Pittsburgh Section awarded to Dr. Max A. Lauffer, 224
  1959 Dexter Award awarded to Prof. John Read, 1304
American College and the Educated Life (Dr. Douglas M. Knight), 1769
American Documentation Institute, and others : International Conference on Scientific Information, 147
American Embassies : Appointment by the United States Department of State of Science Officers for, 15
American Geographical Society : Expedition to Chile, 17
American Geophysical Union : Grant of 25,000 dollars from the National Science Foundation, for a Conference on Mechanisms of Precipitation Formation, 1372
American Institute of the Aeronautical Sciences : Election of Sir George R. Edwards as an Honorary Fellow, 368
  Election of Dr. A. M. Ballantyne as a Fellow, 368
American Institute of Electrical Engineers (Bell Telephone Laboratories and the) : Establishment of the Kelly Award, 510
American Institute of Electrical Engineers, and others : Twelfth Annual Conference on Electrical Techniques in Medicine and Biology, 1434
American Institute of Physics, in co-operation with the National Science Foundation : To publish an English translation of the *Astronomical Journal of the Academy of Sciences*, U.S.S.R., under title *Soviet Astronomy–AJ*, 1164
American Marine Life, *review* by Dr. D. P. Wilson, 852
American Miniature Nuclear Generator, *SNAP III* (W. S. Eastwood, L. B. Mullett and J. L. Putman), 643
American Museum of Natural History : *Curator*, Vol. 1, No. 1, 223
  Bulletin, Vol. 116, Art. 1, The Spider Family Dictynidae in America North of Mexico (Prof. Ralph V. Chamberlin and Willis J. Gertsch), 1170
American Naturalists : Early, *review* by Dr. L. Harrison Matthews, 1006
American Negroes : Haptoglobin Types in (Dr. Eloise R. Giblett), 192
American Schools : Laboratory Equipment in, 1163
American Science : A Statement by the President, and Strengthening—a Report of the President's Science Advisory Committee, 1215
American Secondary Schools : Mathematics in, 1366
American Society of European Chemists : Neuberg Medal awarded to Dr. H. Albert Barker, 1304
American Society of Mechanical Engineers and Purdue University Thermophysical Properties Research Center : Symposium on the Thermal Properties of Gases, Liquids and Solids, 294
American Society of Metals : Appointment of Allan Ray Putnam as managing director, 1094
American Society of Metals (Eastern New York Chapter) : Conference on the Fracture of Engineering Materials, 1368
American (Latin) Congress of Chemistry : Seventh (Mexico), 294
American (North) *Daphnia* : The Systematics of (Dr. John Langdon Brooks), 93
Amide (Lysergic Acid Diethyl): Quantitative Measurement of the Effect of, on Mice and its Interactions with other Drugs (Dr. J. R. Smythies), 545
Amide Groups and Ammonia : Production of, in the Radiolysis of Aqueous Solutions of Protein (Dr. Winifred Bennett and Dr. Warren M. Garrison), 889
Amides (Amino-Acid), and Amino-Acids : Relationship between Proton and Metal Binding by some Peptides, (Dr. S. P. Datta, R. Leberman and Dr. B. R. Rabin), 745

Amine (Diphenyl) : Effects of Starvation and, on Carotenoids in *Phycomyces* (T. N. R. Varma, Prof. C. O. Chichester and G. Mackinney), 188
Amineoxidase : Quantitative Estimation of (Dr. George C. Cotzias and Dr. James J. Greenough), 1732
Amines (Pressor), and Neuroblastoma (Dr. J. D. P. Graham), 1733
Amino-Acetone; its Isolation and Role in Metabolism (Dr. W. H. Elliott), 1051
Amino-Acid (A New), in *Stizolobium hassjoo* : Stizolobic Acid (Prof. A. Hattori and Dr. A. Komamine), 1116
Amino-Acid Amides and Amino-Acids : Relationship between Proton and Metal Binding by some Peptides, (Dr. S. P. Datta, R. Leberman and Dr. B. R. Rabin), 745
Amino-Acid Composition of the Proteins of Barley Leaves in relation to the Mineral Nutrition and Age of Plants (Dr. B. P. Pleshkov and Dr. L. Fowden), 1445
Amino-Acid Esters : Inhibitory Action of, on the Production of Extracellular Amylase by *Penicillium chrysogenum* (Dr. L. Horváth, S. Bajusz and A. Szentirmai), 477
Amino-Acid Metabolism in Wool Roots (G. E. Rogers and P. H. Springell), 993
Amino-Acid Sequences of the Corticotropins : Patterns in the (Drew Schwartz), 464
Amino-Acid Transport : An Effect of Insulin on Peptide Synthesis independent of Glucose or (Prof. Ira G. Wool and Dr. M. E. Krahl), 1399
Amino-Acids : Activation of, in relation to the Synthesis of Silk Proteins (Prof. J. Heller, Dr. P. Szafrański and Dr. E. Sulkowski), 397
  Relationship between Proton and Metal Binding by some Peptides, Amino-acid Amides and (Dr. S. P. Datta, R. Leberman and Dr. B. R. Rabin), 745
Amino-Acids in Aqueous Solutions : Effects of Gamma-Radiation on some Carbohydrates, Hydroxyacids and (Dr. S. A. Barker, Dr. P. M. Grant, Prof. M. Stacey and Dr. R. B. Ward), 376
Amino-Acids labelled with Carbon-14 : Effect of Streptomycin on the Incorporation of, into Ribonucleic Acid and Protein in a Cell-free System of a *Mycobacterium* (T. Erdös and Agnes Ullmann), 618
Amino-Acids of Silk : Utilization of the Carboxyl Group of Glycine for the Synthesis of the, by *Bombyx mori* (Dr. S. Bricteux-Grégoire, W. G. Verly and Prof. M. Florkin), *erratum*, 294
p-Aminobenzylpenicillin : Penicillin Derivatives of (A. Ballio, Prof. E. B. Chain, F. Dentice di Accadia, Dr. G. N. Rolinson and F. R. Batchelor), 180, *erratum*, 224
γ-Aminobutyric Acid and Glutamic Acid Content of Brains of Rats treated with Toxopyrimidine (Dr. G. Rindi and G. Ferrari), 608
β-Aminoethyl*iso*thiouronium Dibromide : Anti-Thyroid Action of, in Rats (John Osmer, Dr. Robert B. Jennings and Dr. Robert M. Dowben), 470
β-Aminoethylthiosulphuric Acid : Protective Effect of, against Ionizing Radiation (Bo Holmberg and Bo Sörbo), 832
β-Amino-*iso*butyric Acid : Urinary Excretion of, in Eskimo and Indian Populations of Alaska (Dr. A. C. Allison, Dr. B. S. Blumberg and Dr. S. M. Gartler), 118
6-Aminopenicillanic Acid in Penicillin Fermentation : Synthesis of Penicillin —(F. R. Batchelor, F. P. Doyle, J. H. C. Nayler and Dr. G. N. Rolinson), 257
Aminopeptidase Activity in Cancer Cells (R. G. J. Willighagen and H. T. Planteydt), 263
Aminopeptidase (Leucine) Activity in Mast Cells (Dr. O. Braun-Falco and Dr. K. Salfeld), 51
'Aminopterin' : Selection of Bacterial Mutants of Increased Sensitivity to (Dr. Charles A. Nichol), 550
Amiran, Ruth, and others : Hazor I, an Account of the First Season of Excavations, 1955 (The James A. De Rothschild Expedition at Hazor), *review* by Peter J. Parr, 951
Ammonia : Production of Amide Groups and, in the Radiolysis of Aqueous Solutions of Protein (Dr. Winifred Bennett and Dr. Warren M. Garrison), 889
Ammonia Nitrogen : Assimilation of, by Rumen Bacteria (A. T. Phillipson, Marjorie J. Dobson and T. H. Blackburn), 402
Ammonium (Fixed), from the Soil : Release of, by Ball Milling (P. M. McDonnell, Prof. F. J. Stevenson and Dr. J. M. Bremner), 1414
Ammonium Dihydrogen Phosphate Crystals : Effect of Tartar Emetic on the Growth of (Yutaka Kunisaki), 105
Ammonium Sulphate Solutions : A Rapid Method for determining the Concentration of (Dr. John A. Whitaker and Dr. Robert Hughes), 603
Amniotic Fluid : Effect of, on Inhibition of Growth by Cortisone in Chicken Embryos (Dr. P. de Franciscis and Prof. W. Landauer), 617
Amniotic Fluid and the Foetal Lung (Bernard Towers), 1140
Amoebae : Utilization of Nutritive Spheres in the *Proteus* Group of (Sister Monica Taylor), 1458
Amoebae during Pinocytosis : Molecular Orientation at the Surface of (Ronald C. Rustad), 1058
Amounts (Small), of Water in Fluids : An Automatically Operating, Coulometric Titration Method for continually measuring (E. Barendrecht), 1181
AMPERE (Groupement), (Radio Frequency Spectroscopy Group and the) : Joint Meeting on the Study of Molecular and Atomic Motions in Solids and Liquids by Radiofrequency Methods, 652
Amperometric Determination of Sulphydryl Content of Blood and Tissues (Dr. S. K. Bhattacharya), 1327
Amphetamine Psychosis (Dr. P. H. Connell), *review* by Dr. W. R. Bett, 639
Amphibians of the United States and Canada East of the 100th Meridian : A Field Guide to Reptiles and (Rogert Conant), *review* by A. G. C. Grandison, 958
Amphibians and Reptiles : Fossil (Dr. W. E. Swinton), second edition, *review*, 73
Amplifiers (Magnetic) : The Theory and Design of (Dr. E. H. Frost-Smith), *review* by J. G. Henderson, 1627
Amphipod, *Hyperia galba*, an Ectoparasite of the Jelly-fish, *Cyanea capillata* (Prof. Erik Dahl), 1749
Amylase (Extracellular) : Inhibitory Action of Amino-Acid Esters on the Production of, by *Penicillium chrysogenum* (Dr. L. Horváth, S. Bajusz and A. Szentirmai), 477
Amylo Process : Unfermentable Sugars in Barley Mash fermented by the (Hideo Ono and Michio Dazai), 1055
Amyloid of Diverse Origins : Electron Microscopic Observations on a Fibrous Component in (Dr. Alan S. Cohen and Dr. Evan Calkins), 1202
Amylose : Synthesis of, by Potato D-Enzyme (Dr. Gwen J. Walker and Dr. W. J. Whelan), 46
Anaerobic Digestion : Gas–Chromatographic Observation of the Reduction of Carbon Dioxide to Methane during (J. Chmielowski and Peter C. G. Isaac), 1120
Analbuminaemic Subject : Albumin labelled with Iodine-131 in an (T. Freeman, C. M. E. Matthews, Dr. A. S. McFarlane, H. Bennhold and E. Kallee), 606
Analisi : La Disputa Leibniz–Newton sull' (translated into Italian by Dr. G. Cantelli), *review* by L. Roth, 1081
Analogues (Lipid-soluble), of Acetylcholine : Distinction between Sodium and Potassium in Change in Permeability effected by (Dr. Wolf D. Dettbarn), 465
Analysis : Biochemical, *review* by Dr. I. D. P. Wootton, 779
  Colorimetric (Noel L. Allport and Dr. J. W. Keyser), Vol. I, Determinations of Clinical and Biochemical Significance, second edition, *review* by Dr. N. R. Lawrie, 207
  Modern Tauberian, *review* by Prof. T. A. A. Broadbent, 1626
Analysis of Artificial Satellite Orbits : Density of the Atmosphere at Heights between 200 km. and 400 km., from (D. G. King-Hele), 1224
Analysis by Gas Chromatography of a 'Pure' Sample with an 'Impure' Carrier (V. Willis), 1754
Analysis of Hydrocarbons (Dr. H. M. Frey), 743 ; (Dr. J. A. Barnard and Dr. H. W. D. Hughes), 744
Analysis of Light Hydrocarbon Gas Mixtures (Dr. J. A. Barnard and Dr. H. W. D. Hughes), 250
Analysis of Mast Cells by means of Polarization Microscopy (Prof. Leslie Horváth), 1067
Analysis of Noise and Vibration : New Techniques in the (Acoustics Group of the Physical Society and the Institute of Physics Symposium on), 438, 794
Analysis of Scale-rich Material from Wool : Separation and (Dr. J. H. Bradbury), 305
Analysis (Applied), in the U.S.S.R., *review* by Prof. T. A. A. Broadbent, 1766
Analysis (Biochemical) : Methods of (edited by Prof. David Glick), Vol. 6, *review* by Dr. I. D. P. Wootton, 779
Analysis (Chemical) : Magnetometric Titration—a New Method of (Dr. M. S. Blackie and Dr. V. Gold), 1804
Analysis (A Chromatographic), for Ricinine (Trevor Robinson and Elvin Fowell), 833
Analysis (Combinatorial) : An Introduction to (John Riordan), *review* by Dr. L. S. Goddard, 970
Analysis (Higher) : Approximate Methods of (L. V. Kantorovich and V. I. Krylov), translated from the Russian by Curtis D. Benster, *review* by Prof. T. A. A. Broadbent, 1766
Analysis (*In vitro*) of a Mammalian Tumour Virus (Dr. Leo Sachs, Dr. Marian Fogel and Ernest Winocour), 663
Analysis (X-Ray Fluorescence) : Estimation of Strontium in Animal Bone using (W. M. B. Roberts), 887
Analytical Chemistry : Separation Processes in (Royal Institute of Chemistry Symposium on), 934
Analytical Chemistry, Society for : Election of Officers, 1024
Analytical Histology and Histo-Chemistry : Methods of (Edward Gurr), *review* by S. Bradbury, 211
Anantaraman, Sita : Metacercaria (Allocreadioidea) in the Planktonic Ctenophore, *Pleurobrachia globosa* Moser 1903, from the Madras Coast, 1407
Anatomical, Physiological and Anthropometric Principles in the Design of Office Chairs and Tables (Dr. W. F. Floyd and Dr. D. F. Roberts), 1022
Anatomie de *Latimeria chalumnae* (J. Millot et J. Anthony), Tome I, Squelette, Muscles et Formations de Soutien, *review* by Dr. E. Trewavas, 566
Anatomy of a Coelacanth, *review* by Dr. E. Trewavas, 566
Anatomy (Comparative) : Zoology and, at Dublin, 1716
Anbar, Dr. M., and others : Effect of Monofluorosulphonate, Difluorophosphate and Fluoroborate Ions on the Iodine Uptake of the Thyroid Gland, 1517
Ancient Ireland, *review* by Joseph Raftery, 1704
Ancient Manure : Marl, an (G. E. Fussell), 214
Ancient Periods : Plant Ecology of (Prof. Tom M. Harris), 1370
Ancillary Mathematics (Prof. H. S. W. Massey and H. Kestelman), *review* by Prof. T. A. A. Broadbent, 1703
Anderson, A. Elving, and others : Variables related to Human Breast Cancer, *review* by Dr. L. Foulds, 955
Anderson, A. J. (Meyer, D. R., and) : Temperature and Symbiotic Nitrogen Fixation, 61
Anderson, B. W. : Gem Testing, sixth edition, *review* by Dr. W. Campbell Smith, 781
Anderson, Helen M., and Turner, Dr. Joseph C. : Preparation and the Haemoglobin Content of Red Cell 'Ghosts', 112
Anderson, J. H. R.: Humid Tropics Vegetation (Tropical Peat-Swamps), 795
Anderson, Prof. J. M. : Emission of Slow Secondary Electrons, 241
Anderson, Prof. John M. (Guthrie, Mary J., and) : General Zoology, *review* by Dr. V. Fretter, 1290
Anderson, Dr. J. S. : Appointed director of the National Chemical Laboratory, Teddington, 1719
Anderson, Dr. Kitty : Appointed a member of the University Grants Committee, 86
Anderson, Dr. P. J. : Electrical Double Layer in Colloid Science (Dispersions of several Inorganic Oxides in Dilute Inorganic Electrolytes), 78
Anderson, S. G. (Ada, G. L., and) : Yield of Infective 'Ribonucleic Acid' from Impure Murray Valley Encephalitis Virus after Different Treatments, 799
Anderson, Comdr. W. R. : Awarded the Patron's Medal of the Royal Geographical Society, 292
Andrea, Dr. J. H. : Relaxation Processes (Ultrasonic Relaxation Measurements in Liquids), 584
Andrew, Prof. E. R., and others: Removal of Dipolar Broadening of Nuclear Magnetic Resonance Spectra of Solids by Specimen Rotation, 1802
Andrewartha, Dr. H. G. : Density-Dependent Factors in Ecology, 200
Andrews, D. R. (Burt, A. D., and) : Stereophonic Sound Recording, Reproduction and Broadcasting (Magnetic Tape Recording), 1720

Androgens in the Bovine Testis and Spermatic Vein Blood (H. R. Lindner), 1605
Andromeda Nebula at 408 Mc./s.: A High-resolution Survey of the (Dr. M. I. Large, D. S. Mathewson and C. G. T. Haslam), 1250
Andrysek, Oskar, and Schück, Ota: Absorption of Radioiodine through the Bladder-Wall in the Rabbit, 893
Anfinsen, Jr., C. B., and others (edited by): Advances in Protein Chemistry, Vol. 12, *review* by Dr. M. F. Perutz, 1290
Angell, Montgomery B.: Awarded the Plaque of the New York Academy of Medicine, 294
Anglo-American Library Associations (R. D. MacLeod), 1021
Anglo-Soviet Educational and other Exchanges: Discussions on (Soviet Relations Committee of the British Council and the Soviet State Committee for Cultural Relations with Foreign Countries), 582
A. or $m\mu$ in Electron Microscopy (Dr. John R. Baker), 416
Angular Momentum: Elementary Theory of (M. E. Rose), *review* by Prof. N. Kemmer, 705
Angular Momentum in Quantum Mechanics (E. R. Edmonds), *review* by Prof. N. Kemmer, 705
Angwin, Sir Stanley: *Obituary* by Sir Gordon Radley, 1638
Angyal, Prof. S. J.: Awarded the H. G. Smith Memorial Medal of the Royal Australian Chemical Institute, 794
3,6 Anhydrogalactosediethylmercaptal: Determination of Galactosediethylmercaptal and, with the Anthrone and Seliwanoff Reagents (W. Yaphe), 44
Anhydrous Gamma Alumina: Evidence for a Variable Long-range Order in nearly (Prof. G. W. Brindley and Dr. M. Nakahira), 1620
Anhydrous Sodium Soaps: Structure of, at High Temperatures (A. Skoulios and Dr. V. Luzzati), 1310
Anhydrous Sodium Sulphate: Polymorphic Transitions in (Dr. C. N. R. Rao and L. V. Gregor), 1391
Aniline (Dimethyl): Kinetic Isotope Effect in the Bromination of (P. G. Farrell and Dr. S. F. Mason), 250
Animal Bone: Estimation of Strontium in, using X-Ray Fluorescence Analysis (W. M. B. Roberts), 887
Animal Bones: Radioactivity of Soils, Plant Ashes and (Sir Ernest Marsden), 924
Animal Book: The Cherry Kearton (Cherry Kearton), *review* by J. E. Hill, 1628
Animal Ecology—Aims and Methods (A. Macfadyen), *review* by Dr. E. B. Ford, 707
Animal Ecology To-day (Prof. F. S. Bodenheimer), *review* by Dr. A. Milne, 1220
Animal Husbandry at the Royal Veterinary College, 365
Animalium: De Motu Locali, 1627 (William Harvey), edited, translated and introduced by Dr. Gweneth Whitteridge, *review* by Prof. K. J. Franklin, 1486
Animals: Harvey on Movement in, *review* by Prof. K. J. Franklin, 1486
  The Work Output of—Flight by Birds and by Man-power (Dr. D. R. Wilkie), 1515
Animals (Domestic), in New Zealand: Diseases of (prepared by the Technical Committee of the New Zealand Veterinary Association, Inc.), *review* by Dr. J. N. Oldham, 967
Animals (Farm): Glycosidases in some (J. Conchie, June Findlay and Dr. G. A. Levvy), 615
Animals (Indian): Status to-day of Four Rare (E. P. Gee), 367
Animals (Laboratory): Effect of 1,6-Di-(2-Bromoethylamino)-1,6-Dideoxy-D-Mannitol Dihydrobromide on Tumours of (Prof. J. Baló, G. Kendrey, J. Juhász and I. Besznyák), 395
Animals (Non-immunized and Immunized): Factors Inhibiting and Stimulating Growth of *Mycobacteria* in the Blood and Serum of (J. Hubáček and I. Málek), 187
Animals (Predatory), in Spain, 1782
Animals (Small): Measuring Productivity in Breeding of (Dr. W. Lane-Petter, Annie M. Brown, Margaret J. Cook, G. Porter and A. A. Tuffery), 339
  A Photographic Method for Recording Activity and Behaviour in a Group of (Dr. D. K. Edwards), 625
Anion Inhibition of α-Glycerophosphate Dehydrogenase (Dr. Otto Z. Sellinger and Dr. O. Neal Miller), 889
Anionic Surface-Active Agents: Decomposition of, by Soil Bacteria (Dr. F. A. Skinner), 548
Annau, E.: Splitting of the Electrophoretic Pattern of Serum Albumin during Short-Term Action of Pepsin at Room Temperature, 190
Annealing (Thermal), of Chemical Radiation Damage (Dr. A. G. Maddock and S. R. Mohanty), 86
Annelids and the Arthropods: Link between the, 1782
Annual Rainfall: World Variation in (J. F. Griffiths), 132
Annual Review of Biochemistry (edited by J. Murray Luck, in association with Frank W. Allen and Gordon Mackinney), Vol. 27, *review* by Prof. F. G. Young, 961
Annual Review of Microbiology (edited by Charles E. Clifton, in association with Sidney Raffel and Mortimer P. Starr), Vol. 12, *review*, 1219
Annual Review of Plant Physiology (edited by A. S. Crafts, in association with Leonard Machlis and John G. Torrey), Vol. 9, *review* by Prof. W. Stiles, 1703
Anodic Films (Aluminium Oxide): Sealing of (Dr. R. M. Hinde, E. A. Kellett and P. H. Harris), 39
Anodic Oxidation: Refractive Index of Uranium Oxide produced by (A. E. Stebbens and Dr. L. L. Shreir), 1113
Anomalous Night-Time Reception of a Major Solar Radio Burst (Prof. Alex. G. Smith, T. D. Carr and W. H. Perkins), 597
Anomaly (Spacing), in Electron Microscope Images of Crystal Lattices (Dr. H. Hashimoto and Dr. H. Yotsumoto), 1001
Anopheles aquasalis Curry: Resistance of, to Dieldrin in Trinidad (T. A. Omardeen), 131
Anopheles gambiae: Relationship between Salinity and Breeding of, in North-Eastern Tanganyika (A. Smith and J. W. Vail), 1203
Anopheline Densities in Huts on the Pare Mountains: Effect of Residual House Spraying in the Plains on (Dr. A. Smith), 198
Ansell, A. D.: Awarded a John Murray Travelling Studentship in Oceanography and Limnology for 1959 by the Royal Society, 1365
Anserine Formation: Pathways and the Physiological Site of (Prof. Theodore Winnick and R. E. Winnick), 1466
Ansevin, Allen T., and Lauffer, Prof. Max A.: Native Tobacco Mosaic Virus Protein of Molecular Weight 18,000, 1601
Anson, D., and others: Examination of Particulate Matter on Filter Membranes, 1000
Anson, M. L., and others (edited by): Advances in Protein Chemistry, Vol. 12, *review* by Dr. M. F. Perutz, 1290
Antagonism of Choline and Inositol (Dr. B. W. Agranoff and M. R. Spivey Fox), 1259
Antarctic Ice-Sheet: Characteristics of the (Royal Astronomical Society and the British Glaciological Society Geophysical Discussion on), 1575
Antarctic Meteorology (Dr. E. B. Kraus), 1503
Antarctic Report (United Kingdom), to the fifth meeting of the Special Committee for the International Geophysical Year, 1718
Antarctic Research, British National Committee on: To co-ordinate British Antarctic Activities, 292
  Appointment of Sir Raymond Priestley as chairman, 292
Antarctic Research Programme, United States: Appointment of Albert P. Crary as chief scientist, 1090
Antarctica: Thickness of the Earth's Crust in (F. F. Evison, C. E. Ingham and R. H. Orr), 306
Antarctica near Mawson, 1956: Marine Studies in the Inshore Waters of (Dr. J. S. Bunt), 1541
Anterior Pituitary: Influence of the, on the Ageing Process in the Ovary (Dr. E. C. Jones and Prof. P. L. Krohn), 1155
Anterior Pituitary Glands (Sheep): Bioassay of (Dr. D. R. Lamond, H. M. Radford and A. L. Wallace),, 1597
Anthocyanidins from Leucoanthocyani(di)ns: Mechanism of Formation of (Dr. David G. Roux and M. C. Bill), 42
Anthocyanins from Plant Extracts: Separation of (Dr. B. V. Chandler and Dr. T. Swain), 989
Anthony, Dr. H. D.: Science and Religion in Seventeenth-Century England, *review*, 964
Anthony, H. S.: Association between Psychomotor Behaviour and Delinquency, 343
Anthony, J. (Millot, J., et): Anatomie de *Latimeria chalumnae*, Tome I, Squelette, Muscles et Formations de Soutien, *review* by Dr. E. Trewavas, 566
Anthracite of the Don: Derivatographic Investigation of the (M. Weltner), 1254
Anthrenus verbasci (L.) (Col., Dermestidae): Control of Diapause by an 'Internal Clock' in (G. M. Blake), 126
Anthrone and Seliwanoff Reagents: Determination of Galactosediethylmercaptal and 3,6 Anhydrogalactosediethylmercaptal with the (W. Yaphe), 44
Anthropological Research, Wenner-Gren Foundation for: Viking Fund Medals and Awards of 1,000 dollars awarded to Prof. Raymond W. Firth, Prof. Henri V. Ballois and Dr. Jesse D. Jennings, 1434
Anthropological Studies, *review* by Dr. Kenneth Little, 70
Anthropology: Cambridge, *review* by Dr. Rodney Needham, 1625
Anthropology, Department of (Government of India): Appointment of N. K. Bose as director, 719
Anthropology (Physical): The Scope of, and its Place in Academic Studies—a Symposium held at the Ciba Foundation, 1957 (edited by D. F. Roberts and J. S. Weiner), *review* by Dr. Kenneth Little, 70
Anthropology (Social): Method in (Prof. A. R. Radcliffe-Brown), edited by Prof. M. N. Srinivas, *review* by Dr. Kenneth Little, 70
Anthropometric Principles in the Design of Office Chairs and Tables: Anatomical, Physiological and (Dr. W. F. Floyd and Dr. D. F. Roberts), 1022
Antibiotic Action of Cycloheximide (Actidione): Reversal of, by Bivalent Metal Ions (M. Blumauerová and J. Stárka), 261
Antibiotic Combinations: Application of Logarithms to the Base 2 in the Use of Exponential Dilution Series for the Study of (H. J. Oskam and A. Koelman), 840
Antibiotic (New), Kanamycin: Basic and Clinical Research of the (Maxwell Finland, and 93 other authors), 1570
Antibiotics (Czechoslovak Academy of Sciences and the Purkyne Medical Society Symposium on), 154
Antibiotics: Micro-volume Drop-plate Assay of (Dr. M. R. S. Iyengar), 684
  New Types of Salting-out Paper Chromatograms of (Dr. Joseph Úri), 1188
Antibodies: Homologous Species Neoplastic (Dr. Hoy A. Cranston and Frederic O. Eggert), 1471
Antibodies (Precipitating), present in the Serum of Cattle recovering from Foot-and-Mouth Disease: Changes in Specificity and Electrophoretic Mobility of the (F. Brown and J. H. Graves), 1688
Antibody: Effect of Hydrolysis by Papain on the Combining Sites of an (Dr. A. Nisonoff and D. L. Woernley), 1325
Antibody (Staphylococcal), in Human Serum: Measurement of a, by a Mouse Protection Test (Dr. Myron W. Fisher), 1692
Antibody Conjugate (Electron-dense): Preparation of an (Prof. S. J. Singer), 1523
Antibody Decay (Passive), in Thyroidectomized Rabbits (Dr. Ignatius L. Trapani, Dr. Allen Lein and Dr. Dan H. Campbell), 982
Antibody Formation: Failure of Ribonucleoprotein to transfer (Dr. B. D. Janković, Dr. K. Isaković and J. Horvat), 1400
Antibody Formation by Isolated Spleen Cells transferred to Recipients in Absence of Homotransplantation Reaction (Dr. Z. Trnka and I. Rîha), 546
Antibody Formation in Tissue Culture (Marvin Fishman), 1200
Antibody Formation by Transferred Cells: Presence of Antigen—a Factor determining the Duration of (Dr. J. Sterzl), 547
Antibody Production: Changes in Lymphocytes during (K. W. Keohane and W. K. Metcalf), 195
Antibody (Serum), and γ-Globulin in Baby Rabbits after Transfer of Ribonucleoprotein from Adult Rabbits (Dr. Miroslava Hrubešova, Dr. Brigitte A. Askonas and Dr. J. H. Humphrey), 97
Anticoagulant Action of Fibrin Surfaces on Mammalian Blood (Dr. A. L. Copley, D. Steichele, M. Spradau and R. S. Thorley), 1683
Anti-complementary Effect (Apparent): Normal Components of Guinea Pig Serum which may cause Antigens to show an (M. M. H. Sewell), 1062
Antifungal Substance in the Corn Plant and its Effect on Growth of Two Stalk-rotting Fungi (N. J. Whitney and C. G. Mortimore), 341
Antigen: Penicillin as an (K. C. Watson, S. M. Joubert and M. A. E. Bennett), 468
  Presence of—a Factor determining the Duration of Antibody Formation by Transferred Cells (Dr. J. Sterzl), 547

Antigen (Group A) : Changes in the, in a Case of Leukaemia (Dr. E. R. Gold, Dr. Geoffrey H. Tovey, W. E. Benney and F. J. W. Lewis), 892
Antigenic Equivocation : Radiosensitivity as a Function of (Dr. L. Cohen and Dr. A. Cohen), 692
Antigenic Relationships : A Critical Test of (Dr. J. G. Feinberg and Hazel Grayson), 987
Antigenic Stimulus of Exsheathing Fluid in Self-Cure of Sheep infected with *Haemonchus contortus* (E. J. L. Soulsby, R. I. Sommerville and D. F. Stewart), 553
Antigens : Estimation of the Size of, by Gel Diffusion Methods (Dr. A. C. Allison and Dr. J. H. Humphrey), 1590
  Viruses, Genes and, *review* by Prof. F. C. Bawden, 636
Antigens to show an Apparent Anti-complementary Effect : Normal Components of Guinea Pig Serum which may cause (M. M. H. Sewell), 1062
Antigens as Specific Precipitates on Paper Electrophoresis Strips : Detection of (S. Buttery), 686
Antigens (A and B), in Platelets : Histochemical Demonstration of (Dr. B. D. Janković and K. Arsenijević), 695
Antigens (Adenovirus) : Study of, by Immunoelectrophoresis (Dr. H. G. Pereira, Dr. A. C. Allison and Dr. C. P. Farthing), 895
Antigens (Liver), of Mouse Hepatitis : Complement Fixation with Tissue Culture and (Dr. Theodore J. Starr and Dr. Morris Pollard), 1690
Anti-Gm : A New Haemagglutinating Substance in the Gm System (Dr. Morten Harboe), 1468
Anti-Locust Research Centre : Annual Report of the Director (1957-58), 703
  Retirement of Dr. B. P. Uvarov from the directorship, 1160
  Appointment of Dr. T. H. C. Taylor as director, 1160
Antimetabolite (Glucose), (2-deoxy-D-glucose) : Inhibition of Influenza Virus Multiplication with a (Prof. Edwin D. Milbourne), 271
Antimicrobial Substances from Resistant and Non-resistant Seeds (Dr. Jasper C. Maruzzella and Dr. Martin Freundlich), 972
Antioxidants (Fat) : Basic Substances as Synergists for (H. S. Olcott and E. J. Kuta), 1812
Anti-Parkinsonian Drugs : Use of 'Tremorine' for screening (E. M. Trautner and S. Gershon), 1462
Antiquarian Horological Society : Annual General Meeting, 1094
Antiserum (Insulin) : Production of Acute Insulin Deficiency by Administration of (P. H. Wright), 829
Anti-Thyroid Action of β-Aminoethyl*iso*thiouronium Dibromide in Rats (John Osmer, Dr. Robert B. Jennings and Dr. Robert M. Dowben), 470
Anti-Tumour Activity of 5-Mercaptouracil (Thomas J. Bardos, Albert Segaloff and Julian L. Ambrus), 612
Anti-Tumour Agents : 'Dual Antagonists' ; Alkyl N-(*bis*-(ethylenimido) phosphoro)-carbamates ; a New Series of (Thomas J. Bardos, Zinon B. Paranastassiou, Albert Segaloff and Julian L. Ambrus), 399
Antiviral Activity of Lysozyme (Prof. Rodolfo Ferrari, Dr. Carlo Callerio and Dr. Giuseppe Podio), 548
Antonini, E., and others : Oxygen Equilibrium of Human Haemoglobin in Strong Salt Solutions, 827
Antropov, P. Y. : The Iron Ore Deposits of the Kursk Magnetic Anomalies, 1028
Ants on a Scent Trail : Interaction between (J. H. Sudd), 1588
Anurans : Number of Fibres in the Optic Nerve and the Number of Ganglion Cells in the Retina of (Dr. H. R. Maturana), 1406
Aorta (Rabbit) : Inhibition of Sensitiveness to Nicotine of, by Reserpine, Hexamethonium, Ethyl Flavone-7-Oxyacetate and other Compounds (Dr. I. Setnikar and M. Ravasi), 898
Aorta, Coronary Arteries and Circulus Willisii of Atherosclerotic Individuals : Composition of Lipids isolated from the (Prof. C. J. F. Böttcher, F. P. Woodford, C. Ch. Ter Haar Romeny, E. Boelsma and C. M. Van Gent), 47
Aortic Medial Calcification and Lowered Metabolism in Ground Squirrels (Dr. George R. Zimmerman and Prof. G. Edgar Folk, jun.), 754
Ape-Man-bearing (The Transvaal), Cave Deposits (C. K. Brain), 1433
Apex (Shoot) : Use of Radioactive Tracers in Studies of the (Dr. A. Booth, Dr. E. G. Cutter, Dr. S. N. Postlethwait, B. R. Voeller and Prof. P. F. Wareing), 1580
Aphid : Secretion of Two Types of Saliva by an (Dr. P. W. Miles), 756
Aphididae (Homoptera) of East Africa : A Study of the (V. F. Eastop), *review* by Dr. W. J. Hall, 208
Aphids : African, *review* by Dr. W. J. Hall, 208
Apolocystis elongata, Phillips and MacKinnon : Observations by Electron Microscopy on the Structure of an Acephaline Gregarine (Dr. D. Lacy and H. B. Miles), 1456
Apparatus and Applications of Mass Spectroscopy, *review* by Prof. K. T. Bainbridge, 638
Apparent Anti-complementary Effect : Normal Components of Guinea Pig Serum which may cause Antigens to show an (M. M. H. Sewell), 1062
'Apparent Protein' in the Human Red Cell : Haemoglobin and (Dr. Eric Ponder), 1330
Appearance of a Phosphorus Compound in Platelet-rich Plasma on Clotting (Dr. G. V. R. Born and Dr. M. P. Esnouf), 478
Appendages of Bacteria : Non-Flagellar (Dr. Charles C. Brinton, jun.), 782
Appendix (Rabbit) : Effects of X- and Ultra-violet Irradiation on the Incorporation of Phosphorus-32 into Isolated Nuclei of (Yuong-Tchel Tchoe and Prof. A. Sibatani), 1334
Apple-Scoops (Dr. J. Menzies Campbell), 1542
Apples (Stored) : Control of Superficial Scale in (W. High Smith), 760
Application of Logarithms to the Base 2 in the Use of Exponential Dilution Series for the Study of Antibiotic Combinations (H. J. Oskam and A. Koelman), 840
Application of Standards of Radioactivity : Preparation, Maintenance and (W. B. Mann and H. H. Seliger), 1023
Applications of the Electron Microscope : Techniques and (Cornell University Annual Summer Laboratory Course in), 1094
Applications to Fundamental Problems of Physics : Information Theory and its (Prof. L. Brillouin), 501
Applications of Mass Spectroscopy : Apparatus and, *review* by Prof. K. T. Bainbridge, 638
Applications of Random Noise Theory : Principles and (Dr. Julius S. Bendat), *review* by R. A. King, 353
Applications (Industrial) : Electronic Digital Computers and their (Conference at the Birmingham College of Technology), 154
Applications (Scientific), of Science, *review* by Dr. Cecil Gordon, 424
Applied Analysis in the U.S.S.R., *review* by Prof. T. A. A. Broadbent, 1766
Applied Bacteriology, Society for : Symposium on Lactobacilli, 1234
Applied Chemistry (Pure and) : Seventeenth International Congress of, 1368
Applied Chemistry (Pure and), International Union of : Formation of a Special Group under the auspices of the Analytical Chemistry Section, to make recommendations for a standard terminology in Gas Chromatography, 722
  Nomenclature of Organic Chemistry, 1957, *review* by Dr. E. H. Rodd, 960
  A Proposed International Chemical Notation (prepared by the Commission on Codification, Ciphering and Punched Card Techniques), tentative version subject to revision, *review* by Dr. E. H. Rodd, 960
Applied Chemistry (Pure and), International Union of (Commission of Geochemistry) : Symposium on Geochemistry, 1719
Applied Chemistry (Pure and), International Union of (organized by the Chemical Society and sponsored by the) : Fourth International Conference on Co-ordination Chemistry, 1784
Applied Mathematics in the Soviet Union, 863
Applied Mechanics (Theoretical and) : Fourth Congress on (Indian Society of Theoretical and Applied Mechanics), 366
Applied Mechanics (Theoretical and), Indian Society of : Fourth Congress on Theoretical and Applied Mechanics, 366
Applied Pharmacology, Toxicology and, Vol. 1, No. 1, 650
Approach (The Biographical), to John Dalton (Frank Greenaway), *review* by Prof. J. R. Partington, 1765
Approach (A Geometrical), to the Structure of Liquids (Prof. J. D. Bernal), 141
Approaches (Experimental), to the Problems of Growth and Form in Plants (Experimental Morphology Group of the Linnean Society Symposium on), 584
Approximate Methods of Higher Analysis (L. V. Kantorovich and V. I. Krylov), translated from the Russian by Curtis D. Benster, *review* by Prof. T. A. A. Broadbent, 1766
Approximate Wave Functions : Use of, for Extrapolation to True Energy Values (P. G. Dickens, Dr. J. W. Linnett and D. Schofield), 175
Aqueous Humour of the Hippopotamus (C. P. Luck and P. G. Wright), 1595
Aqueous Solution : Interaction between Organic Hydroxy Acids and Germanic Acid in (E. R. Clark), 536
Aqueous Solutions : Effects of Gamma-Radiation on some Carbohydrates, Hydroxyacids and Amino-acids in (Dr. S. A. Barker, Dr. P. M. Grant, Prof. M. Stacey and Dr. R. B. Ward), 376
Aqueous Solutions mixed with Solid Crystalline Fluors : Radioassay of (Dr. Daniel Steinberg), 1253
Aqueous Solutions of Protein : Production of Amide Groups and Ammonia in the Radiolysis of (Dr. Winifred Bennett and Dr. Warren M. Garrison), 889
Arabinose and Xylose : Production of Acid from, by Strains of *Azotobacter* (Vagn Jensen), 1536
Arachnida : American (Theodore Savory), 1170
Aragón, F., and others : β-Type Interlamellar Sorption Complexes, 740
'Araldite' : Preparation and Sectioning of Tissues embedded in, for Electron Microscope Examination (J. M. Davis), 200
Arambourg, C., et autres : Archives de l'Institut de Paléontologie Humaine, Mémoire 29, La Grotte de Fontéchevade, Troisième partie, Géologie et Paléontologie, 1369
Araz, A., and others : Action of Nicotinamide on Acetoacetate Metabolism of Liver Homogenates of Normal and Alloxanized Rats, 184
Arc (Electric), in Welding (University of Birmingham Conference on), 1164
Arc Stage of Electrical Discharge : Effects of, on Ignition of Inflammable Gas (I. Berz), 669 ; (W. Nethercot and H. G. Riddlestone), 669
Archaeological Structures : Denudation and Burial of (Formation by Section H of the British Association for the Advancement of Science of a special Committee to investigate the), 1233
Archaeologist : Soils for the (Dr. I. W. Cornwall), *review* by Dr. Alex Muir, 1355
Archer, Dr. R. K. : Feulgen–Naphthoic Acid Hydrazide Reaction applied to Blood Smears, 820
Archer, Dr. R. K., and Flute, P. : Heparin and Thromboplastin Generation in the Horse, 235
Archibald, J. D. H. (Bowman, J.C., and) : Effect of Controlled Lighting on Production Characters in the Fowl, 1138
Architectural Science Review, Vol. 1, No. 1, 1570
Arctic: Meteorological and Ionospheric Studies in the, *review* by James Paton, 279
  Venture to the (edited by R. A. Hamilton), *review* by Dr. T. E. Armstrong, 1081
Arctic Skua : Possibility of Assortive Mating in the (P. O'Donald), 1210
Arends, Dr. Tulio (Gallango de Rodríguez, Dr. M. L., and) : Distribution of Haptoglobins in Native Venezuelans, 1465
Arginase in Rabbit Epithelium : Induction of, by the Shope Rabbit Papilloma Virus (Prof. Stanfield Rogers), 1815
Arginine : Formation of Urea from, in the Brain of the Living Rat (Michael B. Sporn, Wesley Dingman, Alfred Defalco and Robert K. Davies), 1520
Arginine Esterase Activity of 'Blood Thromboplastin' (Phyllis M. Arscott, J. L. Koppel and John H. Olwin), 753
Argus High-Altitude Geophysical Experiments (Dr. Alan T. Waterman and Dr. Detlev W. Bronk), 1019
Arid Zones (Unesco Symposium on), 1234
Arkwrights, 1758-1830 : The Strutts and the—a Study of the Early Factory System (R. S. Fitton and A. P. Wadsworth), *review* by Prof. W. H. G. Armytage, 635
Armarego, W. L. F., and others : Metal-Chelating Properties of Plant-Growth Substances, 1176
Armed Forces—National Research Council Committee on Bio-Astronautics to advise on the Biological or Medical Aspects of Space Exploration, 651
Armour Research Foundation (Information Systems Branch of the Office of Naval Research and the) : Interdisciplinary Conference on Self-Organizing Systems, 86
'Arms and the Man', *review* by R. Brightman, 952
Arms Race : The—a Programme for World Disarmament (Philip Noel-Baker), *review* by R. Brightman, 952
Armstrong, A. H. : Neuro-Mathematics, *review*, 350
Armstrong, D. T., and others : Mechanism of Action of Insulin, 1123

Armstrong, Edward A. : The Folklore of Birds, *review* by M. C. Burkitt, 1422
Armstrong, Dr. E. B. : Satellite Research, *review*, 963
Armstrong, Dr. T. E. : Venture to the Arctic, *review*, 1081
Army Office of Ordnance Research (United States) : Grant of 27,243 dollars to Prof. L. A. Page (University of Pittsburgh), to begin a research programme on Low-energy Nuclear and Electron Physics, 86
Army (British), in the Second World War : Psychiatry in the (Dr. Robert H. Ahrenfeldt), *review* by Dr. D. Russell Davis, 208
Armytage, Prof. W. H. G. : Early Textile Technologists, *review*, 635
Arnold, Dr. A. H. M. : Measurement and Control in Electrical Engineering, 89
Arnstein, Dr. H. R. V. : Radioactive Isotopes in Biochemistry, *review*, 1149
Arnstein, Dr. H. R. V., and Simkin, Dr. J. L. : Vitamin B_{12} and Protein Biosynthesis—Vitamin B_{12} and Biosynthesis in Rat Liver, 523
Aromatic Fluorocarbons : A New General Route to (B. Gething, Dr. C. R. Patrick, Prof. M. Stacey and Prof. J. C. Tatlow), 588
Aromatic Hydrocarbons : Polarography of (H. J. Gardner), 320
Aromatic Hydrocarbons (Polycyclic), added to Wax : Milk as an Eluant of (Dr. Hans L. Falk, Dr. Paul Kotin and Adele Miller), 1184
Aronsson, B., and others : Borides and Silicides of the Platinum Metals, 1318
Arrhenius, Dr. O. : Phosphates and Organic Substances in Nitrogen Deficiency, 513
Arrow, Kenneth J., and others : Studies in the Mathematical Theory of Inventory and Production, *review* by Dr. L. S. Goddard, 1557
Arscott, Phyllis M., and others : Arginine Esterase Activity of 'Blood Thromboplastin', 753
Arsenijevič, K. (Jankovič, Dr. B. D., and) : Histochemical Demonstration of A and B Antigens in Platelets, 695
Art : Aboriginal, *review* by Dr. Phyllis Kaberry, 1080
Art of Grafting, *review* by S. A. Pierce, 958
Art of Lecturing (Dr. G. Kitson Clark and Comdr. E. Bidder Clark), enlarged edition, 1623
Art and Science of Management, 419
Artemia cultured in Sea Water containing Phosphorus-32 : A Sex Difference in Radioactivity of (Prof. Daniel S. Grosch and Mary Ellen Plumb), 122
Arteries of several Species : Distribution of Alkaline Phosphatase in the (Dr. Manuel René Malinow, Martha A. Fernandez, Alvaro L. Gimeno and Grato E. Bur), 1262
Arteries (Coronary), and Circulus Willisii of Atherosclerotic Individuals : Composition of Lipids isolated from the Aorta, (Prof. C. J. F. Böttcher, F. P. Woodford, C. Ch. Ter Haar Romeny, E. Boelsma and C. M. Van Gent), 47
Arthropod-borne Viruses : Plaque Production with Yellow Fever and related (J. S. Porterfield), 1069
Arthropods : Insecticide Resistance in (Dr. A. W. A. Brown), 1508
  Link between the Annelids and the, 1782
Arthurs, A. M. : Appointed lecturer in engineering mathematics at Queen's University, Belfast, 1024
Artificial Aurora : The Samoan (Dr. H. Elliot and J. J. Quenby), 810
Artificial Earth Satellites (Royal Society Programme), 1640
  Deduction of Ionospheric Electron Content from the Faraday Fading of Signals from (W. T. Blackband, B. Burgess, I. L. Jones and G. J. Lawson), 1172
  Table of (Royal Aircraft Establishment), 1566
Artificial Planet : The Russian, 83
Artificial Planet 2, 720
Artificial Planets : Verification of General Relativity by means of (John J. Gilvarry), 666
Artificial Satellite Orbits: Density of the Atmosphere at Heights between 200 km. and 400 km. from Analysis of (D. G. King-Hele), 1224
Artificial Satellites : Corpuscular Radiation and the Acceleration of (Dr. Luigi G. Jacchia), 1662
  Two Atmospheric Effects in the Orbital Acceleration of (Dr. Luigi G. Jacchia), 526
Artificially Induced Residual Stresses : Improvement of the Fatigue Strength of Notched Specimens by (T. R. Gurney), 883
Arts, Royal Society of : Swiney Prize awarded to Dr. Keith Simpson, 368
Arts and Sciences, American Academy of : Rumford Premium for 1959 awarded to Prof. George Wald, 435
Arts and Sciences, Connecticut Academy of : Memoirs, Vol. 13, The Systematics of North American *Daphnia* (Dr. John Langdon Brooks), 93
Arya, V. P. : Awarded a Ciba Fellowship for 1959-1960, 1161
Aryloxy-alkylcarboxylic Acids : Effect of Substitution in the Side-Chain on β-Oxidation of, by *Nocardia opaca* (D. M. Webley, R. B. Duff and V. C. Farmer), 748
Asbestos : Tensile Strength of (R. Zukowski and Dr. R. Gaze), 35
Ascidians : Size Relationship of Oocytes and their Nuclei in Two Species of (S. R. Venkatasubba Rao), 1454
Ascites Carcinoma Cells (Ehrlich) : Energy Compensation in the Crabtree Effect with (K. H. Ibsen, E. L. Coe and Dr. R. W. McKee), 1471
Ascites Tumour Cells : Micro-Electrode Penetration of (B. M. Johnstone), 411
Ascites Tumour Mice : Lithium Retention in /Shirley E. Simon, E. M. Trautner and D. A. Coats), 1128
Ascites Tumours : Possible Enzymic Mechanism for the Development of Resistance against Fluorouracil in (Dr. Peter Reichard and Ola Sköld, and Prof. George Klein), 939
Ascitic Tumours : Activity of 10-Hydroxydecenoic Acid from Royal Jelly against Experimental Leukaemia and (Prof. Gordon F. Townsend, Dr. Joseph F. Morgan and Dr. Barbara Hazlett), 1270
Ascorbic Acid in Germinating Green Gram : Glucose-*cyclo*-Acetoacetate as a Precursor of (Prof. M. C. Nath and M. L. Belkhode), 1258
Ascorbic Acid and similar Reductones : Oxidation of, by Nitrous Acid (Dr. C. A. Bunton and Prof. H. Dahn and Dr. Lotte Loewe), 163
Ascospore in *Neurospora crassa* : Linkage of Polygenes controlling Size of (B. T. O. Lee and J. A. Pateman), 698
Aselius, J., and others : Borides and Silicides of the Platinum Metals, 1318
Ash (Fly) : Forest Seedlings and Mycorrhiza Development on (A. Sobotka and J. Materna), 1066
Ashby, Sir Eric : University College, Ibadan, *review*, 137
Ashby, Dr. W. Ross : Appointed director of the Burden Neurological Institute, Bristol, 220 ; work of, 220, 510
  The Mechanization of Thought Processes (Habituation can be demonstrated in a mechanism without any detailed assumptions about its construction), 225
Asherson, G. L. : Elected to a Junior Fellowship by the Beit Memorial Trust, 1569
Ashes (Plant), and Animal Bones : Radioactivity of Soils, (Sir Ernest Marsden), 924
Ashton, Doris M. (Wyngaarden, Dr. James B., and) : Feedback Control of Purine Biosynthesis by Purine Ribonucleotides, 747
Ashton, Dr. E. H. : Natural Selection in Man, 159
Ashton, Dr. G. C. : β-Globulin Polymorphism and Early Foetal Mortality in Cattle, 404
Ashton, P. Shaw : Humid Tropics Vegetation (Tropical Peat-Swamps), 795
Asian Strains of Influenza Virus : New Inhibitor and Erythrocyte Receptor Substances for certain (Gy. Takátsy and K. Barb), 52
Askonas, Dr. Brigitte A., and others : Serum Antibody and γ-Globulin in Baby Rabbits after Transfer of Ribonucleoprotein from Adult Rabbits, 97
Aslib (Scottish Branch) : Annual General Meeting and Conference, 86
Aso, Kiyoshi (Watanabe, Toshiyuki, and): Isolation of Kojibiose from Honey, 1740
Aspartic and Glutamic Acids : Rapid Quantitative Horizontal Paper Chromatography at an Elevated Temperature—Determination of (Henry R. Roberts and Michael G. Kolor), 460
Aspects (Biological), of the Transmission of Disease—Report of the Institute of Biology Symposium (edited by C. Horton-Smith), *review* by Dr. C. W. Dixon, 1221
Aspects (Chemical), of the Production and Use of Grass (Dublin and District Section and the Agriculture Group of the Society of Chemical Industry Symposium on), 1783
Aspects (Immunological), of Allergic Disorders (British Society for Immunology and the British Association of Allergists Symposium on), 296
Aspects (New), of the Genetic Control of Industrial Melanism in the Lepidoptera (Dr. H. B. D. Kettlewell), 918
Aspects (Scientific and Technical), of Health Physics in Atomic Installations (European Nuclear Energy Agency and the Danish Atomic Energy Commission Symposium on), 934
Aspergillus niger : Inhibition of Growth and Respiration of *Ophiobolus graminis* var. *avenae* and, by Cystine (Elizabeth M. C. Turner), 1130
Aspergillus oryzae : Effect of Lytic Enzyme from *Bacillus circulans* and Chitinase from *Streptomyces* sp. on (Koki Horikoshi and Dr. Shigeji Iida), 186
Assay of Antibiotics : Micro-volume Drop-plate (Dr. M. R. S. Iyengar), 684
Assays (Microbiological) : A Source of Error in, attributable to a Bacterial Inhibitor in Distilled Water (S. A. Price and L. Gare), 838
Assimilation of Ammonia Nitrogen by Rumen Bacteria (A. T. Phillipson, Marjorie J. Dobson and T. H. Blackburn), 402
Assimilation of Organic Carbon by Bacteria : Role of Poly-β-Hydroxybutyric Acid in the (Prof. M. Doudoroff and Prof. R. Y. Stanier), 1440
Assimilation (Genetic), of Acquired Characters : Canalization of Development and (Prof. C. H. Waddington), 1654
Assistance : Technical (International Atomic Energy Agency), 864
Assistance (Technical), under the Baghdad Pact, 1367
Assistance Programmes : Technical (International Co-operation Administration), 1163
Association between Psychomotor Behaviour and Delinquency (H. S. Anthony), 343
Assortative Mating and Reciprocal Difference in the Blue–Snow Goose Complex (Dr. F. G. Cooch and Dr. J. A. Beardmore), 1833
Assortive Mating : Possibility of, in the Arctic Skua (P. O'Donald), 1210
Astapenko, P. D. : Antarctic Meteorology, 1504
Astbury, A. K. : The Black Fens, *review* by Dr. M. A. Morgan, 965
Astrolabe made by Regiomontanus on exhibition at the National Maritime Museum, 508
Astronautical Federation, International : Tenth Congress, 934
Astronomer's Universe (Prof. Bart J. Bok), *review* by Sir H. Spencer Jones, 1221
Astronomical Ephemeris, 1960 (D. H. Sadler), 1705
Astronomical Journal of the Academy of Sciences, U.S.S.R. : English translation to be published by the American Institute of Physics in co-operation with the National Science Foundation, under the title *Soviet Astronomy—AJ*, 1164
Astronomical Society, Royal : Gold Medal awarded to Dr. R. A. Lyttleton, 151
  Eddington Medal awarded to Dr. J. S. Hey, 151
  Election of Prof. R. O. Redman as president for 1959-60, 510
  Discussion on Turbidity Currents, 657
  Geophysical Discussion on the Automatic Reduction of Geophysical Data, 1166
Astronomical Society (Royal), and the British Glaciological Society : Geophysical Discussion on Characteristics of the Antarctic Ice-Sheet, 1575
Astronomy : Popularizing, 1019
  Report on the Progress of (J. H. Oort, F. T. Kerr and G. Westerhout), 1308
Astronomy (Radio) : Maser Observations in (L. E. Alsop, J. A. Giordmaine, C. H. Mayer and C. H. Townes), 223
Asymmetric Hydrolysis of Diethyl Acetamidomalonate by Chymotrypsin (Prof. Saul G. Cohen and Lucille Altschul), 1678
Atack, Dr. E. A. : Self-regulation in Living Systems (Knowledge of the Nervous System), 370
Atheromatosis (Rabbit) : Lack of Effect of Histidine on (Dr. G. G. Pinter and Dr. D. B. Zilversmit), 1272
Atheromatous Tissue (Normal and) : Liquid Crystals of Lipid in (G. T. Stewart), 871
Atherosclerosis (Experimental) : Disturbance in the Pattern of Serum Proteins in, and its Prevention (Prof. M. C. Nath, A. Saikia and B. I. Uppin), 894
Atherosclerotic Individuals : Composition of Lipids isolated from the Aorta, Coronary Arteries and Circulus Willisii of (Prof. C. J. F. Böttcher, F. P. Woodford, C. Ch. Ter Haar Romeny, E. Boelsma and C. M. Van Gent), 47
Atkins, Dr. W. R. G. : *Obituary* by Dr. F. S. Russell, 1228
Atlantic : A Lunar Radio Communication Link across the, 1500
Atlantic Coast of France : *Balanus tulipiformis* Ellis on the (B. S. Kisch), 341
Atlantic Eel Problem : A New Solution to the (Dr. Denys W. Tucker), 495
Atlantic Fisheries (North West), International Commission for the, and others : International Conference on Fishery Statistics, 1783

Atlas Satellite (1958ζ) : The United States, 17
Atmosphere : Cosmic Dust in the (Dr. D. W. Parkin and W. Hunter), 732
Atmosphere at Heights between 200 km. and 400 km. : Density of the, from Analysis of Artificial Satellite Orbits (D. G. King-Hele), 1224
Atmosphere (Polar) Symposium, Oslo, 1956 : Part I, Meteorology Section (edited by R. C. Sutcliffe), Part 2, Ionospheric Section (edited by K. Weekes), *review* by James Paton, 279
Atmosphere (Upper) : Density of the (Dr. George Grimminger), 811
  Irregularities in the Density of the—Results from Satellites (D. G. King-Hele and D. M. C. Walker), 527
  Origin of Sodium and Lithium in the (Dr. T. M. Donahue), 1480
Atmosphere (Upper) Lithium Atoms responsible for the New Twilight Airglow at 6708 A. : Origin of (D. R. Barber), 384
Atmospheres (96,000) : Fusion Curve of Iron to—Temperature of the Earth's Core (Dr. H. M. Strong), 1381
Atmospheric Dust and Fluorescence (Dr. K. Przibram), 1048
Atmospheric Effects in the Orbital Acceleration of Artificial Satellites : Two (Dr. Luigi G. Jacchia), 526
Atmospheric Ice Nuclei : Volcanoes as a Source of (K. Isono, M. Komabayasi and A. Ono), 317
Atmospheric Pollen in relation to Land Use (H. A. Hyde), 1694
Atmospheric Research Group of Pasadena : Grant of 57,100 dollars from the National Science Foundation, to conduct field studies in cloud physics related to nucleation, hydrometeor development, electrification, and cloud dynamics, 1371
Atmospheric Temperatures, 864
Atmospheric Tides and Earth Satellite Observations (D. G. Parkyn), 1045 ; (G. V. Groves), 1047
Atmospheric Turbulence : Flying Locusts and (Dr. R. C. Rainey), 1367
Atomic Comforts, *review* by Prof. G. O. Jones, 1077
Atomic Electron Affinities (H. R. Johnson and Dr. F. Rohrlich), 244
Atomic Energy : Peaceful Uses of (Technical Films used at the Geneva Conference available from the United States Atomic Energy Commission), 721
Atomic Energy Agency (International): Pamphlet on Technical Assistance, 864
Atomic Energy Authority (United Kingdom) : Appointment of L. Grainger as head of the Metallurgy Division, 84
  Fuller use of microphotography in order to make atomic information more easily available, 365
  Appointment of Dr. Nyman Levin as director of the Weapons Group, 582
  Sir William Penney to succeed Sir John Cockcroft as member for research, 582
  Appointment of E. F. Newley as deputy director of the Weapons Group, 582
  The Nuclear Power Station at Chapelcross, 649
  Re-organization of the production and marketing of radioactive isotopes, 720
  Change in the organization of the, 861
  Appointment of D. W. Fry as director of the Atomic Energy Research Establishment, Winfrith, 861
  Appointment of Prof. F. A. Vick as deputy director of the Atomic Energy Research Establishment, Harwell, 861
  The Chapelcross Nuclear Power Station (J. C. C. Stewart), 1361
Atomic Energy of Canada, Ltd., and Queen's University, Kingston, Ontario : International Conference on Nuclear Structure, 1571
Atomic Energy Commission (Danish), (European Nuclear Energy Agency of the Organization for European Economic Co-operation and the) : Symposium on the Scientific and Technical Aspects of Health Physics in Atomic Installations, 934
Atomic Energy Commission (French) : The Nuclear Research Centre, Grenoble, 858
Atomic Energy Commission (United States) : Charges for Uranium-233 and Plutonium, 84
  Grant of 25,421 dollars to Prof. W. E. Wallace (University of Pittsburgh), to continue an investigation of the application of chemical thermodynamics to study the formation of metallic alloys, 86
  Training Courses at the Shippingport Atomic Power Station, 153
  SPERT III achieves criticality at the National Reactor Testing Station, Idaho Falls, 365
  Grants for Training Courses, 437
  Availability of Technical Films used at the Geneva Conference on the Peaceful Uses of Atomic Energy, 721
  Criticality reached by the Transient Reactor Test Facility (TREAT), 862
  Grants to American Colleges and Universities for Nuclear Training in the Biological Sciences, 1091
  Grants for Training in Radioisotope Technology, 1641
  Replacement sheets for Sullivan's Trilinear Chart of Nuclides, 1719
Atomic Energy Research Establishment, Harwell : Second Course at the Harwell Reactor School on the Control and Instrumentation of Reactors, 153
  Course for Senior Technical Executives in Industry, at the Harwell Reactor School, 224
  Appointment of Prof. F. A. Vick as deputy director, 861
  Courses at the Harwell Reactor School, 1643
Atomic Energy Research Establishment, Winfrith : Appointment of D. W. Fry as director, 861
Atomic Installations : The Scientific and Technical Aspects of Health Physics in (European Nuclear Energy Agency and the Danish Atomic Energy Commission Symposium on), 934
Atomic Lithium : Electron Affinity of (E. Holøien), 173
Atomic Mechanisms of Fracture (U.S. National Academy of Sciences, the U.S. National Science Foundation, the Office of Naval Research and the Air Force Office of Scientific Research International Seminar on), 154
Atomic Motions (Molecular and), in Solids and Liquids : The Study of, by Radiofrequency Methods (British Radio Frequency Spectroscopy Group and the Groupement AMPERE Joint Meeting on), 652
Atomic Physics and Human Knowledge (Dr. Niels Bohr), *review* by Prof. W. H. McCrea, 1218
Atomic Power Company, Japan : Construction of a 150-MW. Atomic Power Station, 1019
Atomic Power Station for Japan, 1019
Atomic Power Station (Shippingport) : Training Courses at the (United States Atomic Energy Commission), 153
Atomic Reactor : First Hungarian, 1162
Atomic Weight : Isotopic Composition of Boron and its (W. J. Lehmann and I. Shapiro), 1324
Atomization (Heterogeneous), of Hydrogen and Oxygen (Dr. D. Brennan and P. C. Fletcher), 249
Atoms (Upper-Atmosphere Lithium), responsible for the New Twilight Airglow at 6708 A. : Origin of (D. R. Barber), 384
Atoms and Molecules (Free) : Radiofrequency Spectroscopy of (Radiofrequency Spectroscopy Group Autumn Meeting on), 1502
Aucuba Mosaic Virus (Tomato) : Persistence of, in Dried Leaf Tissue (Prof. John Caldwell), 1142
Audio-direction Finding in the Porpoise (*Phocaena phocaena*), (W. H. Dudok van Heel), 1063
Audrieth, Prof. Ludwig F. : Appointed Science Officer in the American Embassy in Bonn, 15
Audus, Prof. L. J. : Experimental Approaches to the Problems of Growth and Form in Plants (Mechanism of Correlation in Plant Development), 584
Auerbach, Dr. C. : Radioactive Fall-out, 1773
Augustin, R. : Immunological Aspects of Allergic Disorders (Allergens and other Pollen Antigens), 296
Augustin, R., and others : Immunological Aspects of Allergic Disorders (Immunochemistry of *Cladosporium*), 297
Aurora : Effects of the, on Radio Reception, 579
  The Samoan Artificial (Dr. H. Elliot and J. J. Quenby), 810
Aurorae (Sub-Visual), and Radio Noise Bursts on 4·6 kc./s. : Simultaneous Occurrence of (R. A. Duncan and G. R. Ellis), 1618
Aurorae (Sunlit): Rotational Structure of the 3914 A. N_2^+ Band in (Dr. D. M. Hunten, H. J. Koenig and Prof. A. Vallance Jones), 453
Auroral Echoes : Movement of, and the Magnetic Disturbance Current System (R. S. Unwin), 1044
Auroral Isochasms (Dr. Bengt Hultqvist), 1478
Austin, Dr. C. R. : Entry of Spermatozoa into the Fallopian-Tube Mucosa, 908
Austin, E. E., and others : Upper Air Temperature over the World (Meteorological Office, Geophysical Memoir No. 101), 864
Austin, W. H., and others : Effect of Dietary Phytate on Faecal Absorption of Radioactive Ferric Chloride, 691
Australia : Scientific Research in, 155
Australia, Africa and England : Precambrian Coelenterata from (Dr. M. F. Glaessner), 1472
Australian Academy of Science (under the auspices of the International Union of Biochemistry) : Symposium on Haematin Enzymes, 1571
Australian Chemical Institute, Royal : H. G. Smith Memorial Medal awarded to Prof. S. J. Angyal, 794
Australian Commonwealth Scientific and Industrial Research Organization : Ninth Annual Report (1956-57), 155
  Chemical Research Laboratories, 228
  Appointment of Dr. I. W. Wark as the first director of the Chemical Research Laboratories, 228
  Appointment of Dr. A. L. G. Rees as chief of the new Division of Chemical Physics, 228
  Appointment of Dr. K. L. Sutherland as chief of the new Division of Physical Chemistry, 228
  Rural Research, 228
  Annual Report for 1957-58 of the Division of Electrotechnology, 1781
Australian Defence Standards Laboratories : Annual Report for 1956, 581
Australian Museum Magazine : Vol. 12, No. 12, devoted almost entirely to New Guinea, 1368
Australian National University : Appointment of Dr. A. G. Ogston to the chair of physical biochemistry, 151
  To set up a Field Station for Astronomy, 1091
Australian and New Zealand Association for the Advancement of Science : Future of the, 1303
Australian (South) Museum : *Records* of the, Vol. 13, No. 2, 1092
Australian (Western) Wildflowers : How to Know (Dr. William E. Blackall and Dr. Brian J. Grieve), Part 2, A Key to the Flora of the Temperate Regions of Western Australia, *review* by V. S. Summerhayes, 1628
'Australopithecine' Scoop from Herefordshire (Prof. Raymond A. Dart). 844
Automatic Computing Engine at the National Physical Laboratory (J. H. Wilkinson and D. W. Davies), 22
Automatic Control Theory : Basic (Prof. Gordon J. Murphy), *review* by M. J. Somerville, 211
Automatic Programming of Digital Computers (Brighton Technical College Residential Working Conference on), 438, 1779
Automatic Reduction of Geophysical Data (Royal Astronomical Society Geophysical Discussion on), 1166
Automatically Operating, Coulometric Titration Method for continually Measuring Small Amounts of Water in Fluids (E. Barendrecht), 1181
Automation, Computation and Control : Handbook of (edited by Eugene M. Grabbe, Simon Ramo and Dean E. Wooldridge), Vol. I, Control Fundamentals, *review* by P. H. Hammond, 1556
Autoradiograms for Electron Microscopy : Preparation of (R. T. O'Brien and L. A. George, II.), 1461
Autoradiographic Method for distinguishing Samples labelled with Phosphorus-32 and Sulphur-35 (Dr. W. G. Duncombe), 319
Autoxidation (Alkaline), of Cellulose at Low Alkali Concentration : Catalytic Action of Copper in the (R. I. C. Michie and Dr. S. M. Neale), 534
Autumn Colour and Leaf-fall of Deciduous Woody Plants : Effect of Gibberellic Acid on Development of (Dr. P. W. Brian, J. H. P. Petty and P. T. Richmond), 58
Auxins : Action of, on *Acetabularia* and the Effect of Enucleation (Prof. Kenneth V. Thimann and Dr. Kurt Beth), 946
  Control of Leaf Senescence by (Daphne J. Osborne), 1459
  Effects of, on Membrane Permeability and Pectic Substances in Bean Endocarp (J. A. Sacher and K. T. Glasziou), 757
  Effects of Kinetin, Gibberellic Acid and certain, on the Development of Shoot Buds on the Protonema of *Pohlia nutans* (Dr. G. C. Mitra and Dr. A. Allsopp), 974
Auxins and Nucleic Acid Synthesis in Coleoptile Tissues : Relationship between (B. B. Biswas and S. P. Sen), 1824
Availability of Scientific Information, 135
Available Energy in Thermodynamics, *review* by R.W. Haywood, 353
Average Length of Working Life, 1780

Avery, Dr. Eugene C. (Smaller, Dr. Bernard, and) : Radiation Protection and Free Radicals, 539
Avian Folklore, *review* by M. C. Burkitt, 1422
Aviation : Agricultural, Vol. I, No. I (European Agricultural Aviation Centre), 720
Aviation Medicine—Selected Reviews (edited by Clayton S. White, W. Randolph Lovelace, II, and Frederic G. Hirsch), review, 1291
Aviation Psychology in Western Europe and a Report on Studies of Pilot Proficiency Measurement (Western-European Association for Aviation Psychology), 1092
Aviation Psychology, Western-European Association for : Publication No. I, Aviation Psychology in Western Europe and a Report on Studies of Pilot Proficiency Measurement, 1092
Avoirdupois Pound for Science and Technology : The Yard and the, 80
Axelrad, A. A., and others : A Cytopathogenic Agent from a Mammary Tumour in a C3H Mouse that produces Tumours in Swiss Mice and Hamsters, 1535
Axelrod, Dr. Julius, and others : Enzymatic N-Methylation of Histamine, 680
Axon Membrance (Squid) : Excitation of the, in Isosmotic Potassium Chloride (Dr. John W. Moore), 265
Ayer, Prof. A. J. : Appointed to the Wykeham chair of logic in the University of Oxford, 792 ; work of, 792
Aylmore, L. A. G., and Quirk, Dr. J. P : Swelling of Clay–Water Systems, 1752
Azaserine (o-Diazoacetyl-L-serine) : Effect of, on the Pyridine Nucleotide Levels of Mouse Liver (Stuart A. Narrod, Thomas A. Langan, Jun., Prof. Nathan O. Kaplan and Abraham Goldin), 1674
Azeotropic Data : Physical and—Hydrocarbons and Sulphur Compounds boiling below 200° C. (G. Claxton), *review* by Dr. B. A. Rose, 709
Azide (Thallous) : Absorption Spectra and Associated Photoconductivity of Pure and Decomposed Crystals of (B. L. Evans and A. D. Yoffe), 1241
Azo Dye (Carcinogenic) : Prevention of Adaptive Formation of Tryptophan Peroxidase by a (Dr. Silvio Fiala and Anna E. Fiala), 1532
Azotobacter : Production of Acid from Arabinose and Xylose by Strains of (Vagn Jensen), 1536

BABICKY, A., and others : Labelling of Radiographic Contrast Media with Iodine-131, 1474
Babies with Multiple Malformations : Co-existence of the Embryonic (Third Normal) Haemoglobin Fraction with Erythroblastosis in the Blood of Two Full-term New-born (Prof. I. Halbrecht, Ch. Klibanski and F. Bar Ilan), 327
Baby Rabbits : Serum Antibody and γ-Globulin in, after Transfer of Ribonucleoprotein from Adult Rabbits (Dr. Miroslava Hrubešova, Dr. Brigitte A. Askonas and Dr. J. H. Humphrey), 97
Bacharach, A. L. : Elected president of the Nutrition Society, 1643
Bacigalupo, G., and others : Influence of L-3', 5, 3-Triiodothyronine on the Oxidative Phosphorylation of Tumour Mitochondria, 1534
Bacillus anthracis : Inactivation of Spores of, by γ-Radiation (T. Horne, G. C. Turner and A. T. Willis), 475
Bacillus cereus growing synchronously out of Spores : Pattern of Synthesis of Deoxyribonucleic Acid in (Dr. I. Elizabeth Young and Prof. Philip C. Fitz-James), 372
Bacillus cereus and *Bacillus megaterium* : Differences in Cyst(e)ine Content between Vegetative Cells and Spores of (Vladimír Vinter), 998
Bacillus circulans : Effect of Lytic Enzyme from, and Chitinase from *Streptomyces* sp. on *Aspergillus oryzae* (Koki Horikoshi and Dr. Shigeji Iida), 186
Bacillus megaterium: Differences in Cyst(e)ine Content between Vegetative Cells and Spores of *Bacillus cereus* and (Vladimír Vinter), 998
Back Grant of the Royal Geographical Society awarded to David Stratton, 292
Background (Family), and Educational Progress in Scotland : Intelligence, *review* by Jean Floud, 493
Background Gamma-Radiation : Increase in, and its Correlation with Iodine-131 in Milk (Measurements at Leeds following the Windscale Reactor Accident, (Prof. F. W. Spiers), 517
Backhurst, Dr. J. D., and others : Determination of the Yields of Molecular Hydrogen Peroxide in the Radiolysis of Water labelled with Oxygen-18, 176
Bäckström, Prof. Matts : Kältetechnik, zweite Auflage, bearbeitet und ins Deutsche übertragen von Dr. Eduard Emblik, *review* by Dr. K. Mendelssohn, 1150
Bacon, Dr. G. E., and Dyer, R. F. : Neutron Diffraction at a High-Flux Reactor, 35
Bacq, Prof. Z. M., and others : Comparative Sensitivity to Radiation of Seeds from a Wild Plant grown on Uraniferous and Non-Uraniferous Soils, 1449
Bacteraemia : Leucocytosis in Response to, as a Feature of the Acute Radiation Syndrome in the Plaice (A. Preston), 832
Bacteria : Detection of Sialic Acid in various *Escherichia coli* Strains and in other Species of (Prof. Guy T. Barry), 117
  Linear Transfer of a Potentially Mutant State in (Dr. F. Kaudewitz), 871
  Non-Flagellar Appendages of (Dr. Charles C. Brinton, Jun.), 782
  Role of Poly-β-Hydroxybutyric Acid in the Assimilation of Organic Carbon by (Prof. M. Doudoroff and Prof. R. Y. Stanier), 1440
  Synthesis of Deoxyribonucleic Acid during the Division Cycle of (M. Schaechter, M. W. Bentzon and Prof. O. Maaløe), 1207
Bacteria are given Large Pulses of Radiation : Modification of the Oxygen Effect when (D. L. Dewey and Dr. J. W. Boag), 1450
Bacteria, Protozoa and Diet : A Relationship between some, in Early Weaned Calves (J. Margaret Eadie, Dr. P. N. Hobson and S. O. Mann), 624
Bacteria (Airborne) : Chloramphenicol and the Survival of (S. J. Webb), 1072
Bacteria (Marine) : Adaptation of, to Growth in Media lacking Sodium Chloride (Prof. D. B. Pratt and G. Waddell), 1208
Bacteria (Rumen) : Assimilation of Ammonia Nitrogen by (A. T. Phillipson, Marjorie J. Dobson and T. H. Blackburn), 402
Bacteria (Soil) : Decomposition of Anionic Surface-Active Agents by (Dr. F. A. Skinner), 548
Bacteria-free Culture-filtrate of *Vibrio cholerae* : Enterotoxicity of (Prof. S. N. De), 1533
Bacterial Action in Pond-stored Logs (Eric L. Ellwood and Barton A. Ecklund), 1206
Bacterial Cytoplasm: Effect of Drugs upon Components of (Dr. S. Dagley and J. Sykes), 1608
Bacterial Endospores : Dependence of the Heat Resistance of, on their Dipicolinic Acid Content (Brooks D. Church and Harlyn Halvorson), 124
Bacterial Inhibitor in Distilled Water : A Source of Error in Microbiological Assays attributable to a (S. A. Price and L. Gare), 838
Bacterial Mutants : Production of, with Nitrous Acid (Dr. Fritz Kaudewitz), 1829
Bacterial Mutants of Increased Sensitivity to 'Aminopterin' : Selection of (Dr. Charles A. Nichol), 550
Bacterial Neuraminidase (Receptor-destroying Enzyme) : Purification of (G. L. Ada and E. L. French), 1740
Bacterial Population Studies in the Chemostat, *review* by Dr. A. C. R. Dean, 424
Bacterial Populations maintained in the Chemostat : The Dynamics of (Hermann Moser), *review* by Dr. A. C. R. Dean, 424
Bacterial and Testicular Hyaluronidase (Prof. Ernst Báráany, Lennart Berggren and Lennart Juhlin), 265
Bacteriological, Chemical and Biological Examination of the London Waters for the Years 1955-56 : Thirty-seventh Report on the Results of the (E. Windle Taylor), 798
Bacteriology at Adelaide, 1716
Bacteriology (Applied), Society for : Symposium on Lactobacilli, 1234
Bacteriophage : Neutralization of, by Normal Serum (Andre J. Toussaint and Louis H. Muschel), 1825
Bacteriophage Enrichment in a Liquid Two-Phase System with Subsequent Treatment with 'Freon' 113 (Dr. G. Frick and Dr. P. A. Albertsson), 1070
Bacterium with Fungicidal Activity (W. E. Crawley and D. C. Dodd), 63
Bacterium (A Gram-negative Sporing), from the Rumen (Dr. P. N. Hobson and M. R. Purdom), 904
Bagchi, D. (Basu, T. N., and) : The Nature of Coal (Physical Methods of Studying the Constitution of Coals), 1438
Baghdad Pact : Technical Assistance under the, 1367
Bagnall, Dr. K. W. : Chemistry of the Rare Radioelements—Polonium—Actinium, *review* by G. R. Hall, 962
Bailey, Dr. G. L. J. : Elected president of the Institute of Metals, 1024
  Appointed superintendent of the Development and Research Department Laboratory of the Mond Nickel Co., Ltd., Birmingham, 1432 ; work of, 1432
Bailey, Kenneth, and others (edited by) : Advances in Protein Chemistry. Vol. 12, *review* by Dr. M. F. Perutz, 1290
Bailey, L. : Parasitology (Resistance of Honeybees to Epidemics of a range of Parasites), 1506
Bailey, R. : Facultative Parasitism and Dietary Change in *Harmolita hyalipenne* Walker, 341
Bailey, R., and others : Canadian Caesium-Beam Standard of Frequency, 575
Bainbridge, Prof. K. T. : Apparatus and Applications of Mass Spectroscopy, *review*, 638
Bair, W. J., and others : Induction of Lung Tumours by Radioactive Particles, 408
Baird, Robert Douglas : Appointed a director of Baird and Tatlock (London), Ltd., and of Hopkin and Williams, Ltd., 794
Baird and Tatlock (London), Ltd., and Hopkins and Williams, Ltd. : Appointment of Robert Douglas Baird as a director, 794
Baird-Parker, A. C. (Davis, Dr. G. H. G., and) : Cell-Wall Composition of *Leptotrichia* spp., 1206
Bajusz, S., and others: Inhibitory Action of Amino-Acid Esters on the Production of Extracellular Amylase by *Penicillium chrysogenum*, 477
Bak, Prof. B. : Chemistry and Quantum Chemistry, 158
Baker, E. Alan, and Foskett, D. J. : Bibliography of Food—a Select International Bibliography of Nutrition, Food and Beverage Technology and Distribution, 1936-56, *review* by Dr. Magnus Pyke, 351, 582
Baker, Prof. J. F. : Science and Technology in the University of Bristol—Opening of Queen's Building, 217
Baker, Dr. John R. : A. or mμ in Electron Microscopy, 416
Baker, John William : Electronic Theories of Organic Chemistry, *review* by Dr. R. I. Reed, 777
Baker, R. G. : Elected president for 1960-61 of the Institution of Mining Engineers, 1716 ; work of, 1716
Baker's Yeast : Utilization of Inorganic Sulphate by (Dr. A. Kleinzeller, A. Kotyk and L. Kováč), 1402
Balance Trials with Magnesium-28 in Sheep (Alexander C. Field), 983
Balanced Education : The Need for a, 1075
Balanus amphitrite var. *stutsburi* Darwin : Abnormal Development of the Basis in (Dr. H. G. Stubbings), 1282
Balanus tulipiformis Ellis on the Atlantic Coast of France (B. S. Kisch), 341
Balázs, V., and others : Changes produced in Serum Lipoproteins of Dogs by Cellulose containing Methyl Groups, 1119
Balch, Dr. C. C. : Function of the Rumen (Structure of the Ruminant Stomach and the Movement of its Contents), 1644
Baldwin, W. F., and Salthouse, T. N. : Oxygen Deficiency and Radiation Damage in the Insect *Rhodnius*, 974
Balescu, R. : Problems of Collective Motion in Physics (Gaseous Plasmas), 866
Balfour, Dr. J. G., and others : Nuclear Fuel Cycles (Perturbations due to Fuel Cycles), 1647
Balfour, Dr. W. E., and others : Changes in the Secretion of 20α-Hydroxy-pregn-4-en-3-one by the Adrenal Gland of Young Calves, 467
Balfour-Browne, Prof. Frank : British Water Beetles, Vol. 3, *review* by Dorothy J. Jackson, 1420
Ball, F. K. : Antarctic Meteorology, 1503
Ball Milling : Release of Fixed Ammonium from the Soil by (P. M. McDonnell, Prof. F. J. Stevenson and Dr. J. M. Bremner), 1414
'Ball' Mills : Grinding at Super-Critical Speeds in (Dr. H. E. Rose and M. D. Trbojević), 813

Ballance, P. E. (Crombie, Dr. W. Mary, and) : Synthesis of Long-Chain Fatty Acids from 2-^{14}C-Acetate and ^{14}C-Glucose in *Trichoderma viride*, 1195
Ballantyne, Dr. A. M. : Elected a Fellow of the American Institute of the Aeronautical Sciences, 368
Ballay, Dr. Marcel : *Obituary*, 647
Ballio, A., and others : Penicillin Derivatives of *p*-Aminobenzylpenicillin, 180, *erratum*, 224
Baló, Prof. J., and others : Effect of 1,6-Di-(2-Bromoethylamino)-1,6-Dideoxy-D-Mannitol Dihydrobromide on Tumours of Laboratory Animals, 395
Balogh, Dr. Johan : Lebensgemeinschaften der Landtiere, zweite Auflage, *review* by A. Macfadyen, 966
Balsley, J. R., and others : Magnetostriction and Palaeomagnetism of Igneous Rocks, 1318
Bamboos of Malaya (R. E. Holttum), 1169
Bamboos and Nutmegs, 1169
Bamford, Dr. C. H., and others : The Kinetics of Vinyl Polymerization by Radical Mechanisms, *review* by Prof. C. E. H. Bawn, 637
Bananas: Vascular Wilt Disease of, caused by *Fusarium oxysporum* f. *cubense* (R. H. Stover), 1782
Band Spectra (Diatomic) : Changes in Transition Probability due to the Interaction of Rotation and Vibration in (R. C. M. Learner and Dr. A. G. Gaydon), 242
Bands and Lines (New), in the Twilight Sky Spectrum (I. A. Khvostikov and T. G. Megrelishvili), 811
Banks, B. E. C., and others : Glutamic–Aspartic Transaminase of Pig Heart Muscle, 1187
Banks, Dr. C. J. : Proceedings of a Symposium on Insect and Food-plant, *review*, 1767
Banks, Sir Joseph : Correspondence of, *review* by Dr. W. B. Turrill, 1353
Banks Letters : The—a Calendar of the Manuscript Correspondence of Sir Joseph Banks preserved in the British Museum, the British Museum (Natural History), and other collections in Great Britain (edited by Warren R. Dawson), *review* by Dr. W. B. Turrill, 1353
Banks, Dr. R. E., and others : Thermal Reactions of Highly Fluorinated *Cyclo*hexadienes, 586
Bannerman, Dr. David A., and Bannerman, W. Mary : Birds of Cyprus, *review* by Sir Landsborough Thomson, 967
Bannerman, W. Mary (Bannerman, Dr. David A., and) : Birds of Cyprus, *review* by Sir Landsborough Thomson, 967
Barabás, jun., Z. : An Induced Mutant in *Triticum carthlicum* with the Diagnostic Feature of *T. vavilovi*, 1349
Bárány, Prof. Ernest, and others : Bacterial and Testicular Hyaluronidase, 265
Barb, K. (Takátsy, Gy., and) : New Inhibitor and Erythrocyte Receptor Substances for certain Asian Strains of Influenza Virus, 52
Barb, Dr. W. G., and others : The Kinetics of Vinyl Polymerization by Radical Mechanisms, *review* by Prof. C. E. H. Bawn, 637
Barber, D. R. : Singing Pattern of the Common Chaffinch, *Fringilla coelebs* Linn., 129
  Origin of Upper-Atmosphere Lithium Atoms responsible for the New Twilight Airglow at 6708 A., 384
Barber, Dr. H. J. : Speaking on the motion 'That the Education of our Future Rulers should be primarily in the Sciences rather than the Humanities', 1236
Barbier, Dr. G. : Phosphates and Organic Substances in Nitrogen Deficiency, 513
Barbiturate Nystagmus and the Mechanisms of Visual Fixation (C. Rashbass), 897
Barbiturates : Identification of (Dr. A. S. Curry), 1052
Barbour, Dr. A. K., and others : Thermal Reactions of Highly Fluorinated *Cyclo*hexadienes, 586
Barclay, A. : Retirement as keeper of the Department of Chemistry in the Science Museum, London, 224
Bardos, Thomas J., and others : 'Dual Antagonists' ; Alkyl N-(*bis*-(ethylenimido)phosphoro)-carbamates ; a New Series of Anti-Tumour Agents, 399
  Anti-Tumour Activity of 5-Mercaptouracil, 612
Barendrecht, E. : An Automatically Operating, Coulometric Titration Method for continually Measuring Small Amounts of Water in Fluids, 1181
Barer, Dr. R. : Physical and Chemical Exploration of the Cell, *review*, 1355
Bargmann, Prof. Wolfgang : Elected a member of the Anatomy Section of the Deutsche Akademie der Naturforscher Leopoldina, 652
Barker, Dr. H. Albert : Awarded the Neuberg Medal of the American Society of European Chemists, 1304
Barker, Dr. S. A., and others : Effects of Gamma-Radiation on some Carbohydrates, Hydroxyacids and Amino-Acids in Aqueous Solutions, 376
  Identification of 10-Hydroxy-Δ^2-decenoic Acid in Royal Jelly, 996
Barley : Spraying of, with 2,4-Dichlorophenoxyacetic Acid (E. L. Leafe), 621
  Varietal Resistance to Spray Damage in (J. Desmond Hayes), 551
Barley Leaves : Amino-Acid Composition of the Proteins of, in relation to the Mineral Nutrition and Age of Plants (Dr. B. P. Pleshkov and Dr. L. Fowden), 1445
Barley Mash fermented by the Amylo Process : Unfermentable Sugars in (Hideo Ono and Michio Dazai), 1055
Barley Roots : Effect of Phosphorylated Methyl-naphthohydroquinones on the Response to Radiation in (A. D. McKelvie), 1194
Barlow, Dr. H. B. : The Mechanization of Thought Processes (The Coding of Signals in Sensory Mechanisms), 225
Barlow, Prof. H. E. M. : Long-Distance Transmission by Wave-Guide, 727
Barlow, J. : Relaxation Processes (Ultrasonic Techniques to determine the Shear Mechanical Impedance of Lubricating Oils), 584
Barnard, Cyril : *Obituary* by Dr. W. R. Bett, 1159
Barnard, Dr. J. A., and Hughes, Dr. H. W. D. : Analysis of Light Hydrocarbon Gas Mixtures, 250
  Analysis of Hydrocarbons, 744
Barnes, Dr. H. : Elected a Fellow of the Royal Society of Edinburgh, 719
Barnes, M. J., and others : Presence of Griseofulvin in Hair of Guinea Pigs after Oral Administration, 256
Barnes, R. S., and Cottrell, Prof. A. H. : Interfacial Phenomena (Annealing of Radiation Damage in Copper produced by Bombardment with α-particles), 1099
Barnett, S. A. : Darwinism and the Study of Society, 1564
Barr, W. : Elected president of the Iron and Steel Institute, 1234
Barrer, Prof. R. M. : Validity of Clapeyron's Equation for Phase Equilibria involving Clathrates, 463
Barrett, J. : Detection of Hydroxyl Groups in Porphyrins and Chlorins, 1185
Barrier in the Spread Eastwards of Haemoglobin C : The River Niger as a —a Survey of Haemoglobins in the Ibo (Dr. H. Lehmann and Dr. C. Nwokolo), 1587
Barrs, H. D. (Weatherley, Dr. P. E., and) : A Climatological Wind Tunnel, 94
Barry, Prof. Guy T. : Detection of Sialic Acid in various *Escherichia coli* Strains and in other Species of Bacteria, 117
Bartholomew, Prof. J. W., and others : A Correlation between Iodine Permeability and the Gram Characteristic of Cells, 123
Barton, A. D. (Laird, Anna Kane, and) : Cell Growth and the Development of Tumours, 1655
Bartonellas : Characteristics of the, *review* by Dr. A. Lwoff, 207
Bartonellen : Morphologische, Biologische und Serologische Eigenschaften der (Dr. Reinhard Wigand), *review* by Dr. A. Lwoff, 207
Bartram, William: The Travels of (edited by Francis Harper), naturalist's edition, *review* by Dr. L. Harrison Matthews, 1006
Bartram's America : John and William (edited by Helen Gere Cruickshank), *review* by Dr. L. Harrison Matthews, 1006
Barua, D. (Fauconnier, B., and) : Increase of Viral Haemagglutinability of Red Cells of the Mouse after Treatment with Formalin, 629
Basalts (Cretaceous), of Madagascar : Remanent Magnetism of the (Dr. A. Roche and L. Cattala), 1049
Bashir, M. : The Role of the Scholar in Society, 1773
Basic Automatic Control Theory (Prof. Gordon J. Murphy), *review* by M. J. Somerville, 211
Basic Biodynamics (E. J. Kempf), 933
Basic Chromosome Numbers (Two New), in the Musaceae (K. Shepherd), 1539
Basic Physics (Dr. A. R. Meetham), *review* by S. Weintroub, 354
Basic Problems in Propulsion (Advisory Group for Aeronautical Research and Development of NATO Discussion on), 1094
Basic Substances as Synergists for Fat Antioxidants (H. S. Olcott and E. J. Kuta), 1812
Basic and Clinical Research of the New Antibiotic, Kanamycin (Maxwell Finland, and 93 other authors), 1570
Basinki, S. J. (Bland, J. A., and) : Crystal Symmetry of Struvite (Guanite), 1385
Basis in *Balanus amphitrite* var. *stutsburi* Darwin : Abnormal Development of the (Dr. H. G. Stubbings), 1282
Basis (Chemical), for the Classification of Glume Colour in Nigerian Cultivated Sorghums (W. R. Stanton, T. B. Miller and D. L. Curtis), 807
Basis (An Enzymatic), for the Acceleration of Ciliary Activity by Negative Air Ions (Prof. A. P. Krueger and Richard F. Smith), 1332
Basis (Neurological), of Behaviour : Ciba Foundation Symposium on the (edited by G. E. W. Wolstenholme and Cecilia M. O'Connor), (in commemoration of Sir Charles Sherrington, 1857-1952), *review* by Dr. P. B. Bradley, 954
Basis (Physical), for Electrical Engineering (Prof. Thomas L. Martin, Jr.), *review* by Dr. D. A. Bell, 707
Basis (Scientific), of Land Planning in the Tropics (Prof. L. Dudley Stamp), 20
Baskett, Prof. R. G. : Appointed director of the National Institute for Research in Dairying, 294, 365 ; work of, 365
Basolo, F. (Jensen, A., and) : Co-ordination Chemistry (Kinetics of the Substitution Reactions of *bis*cyclopentadienyl Titanium Dihalides), 1784
Bassett, G. A. : Interfacial Phenomena (Nucleation, Orientation and Growth of Vacuum-deposited Metal Films), 1097
Bastenie, Prof. P. A. (Ermans, A. M., and) : Rate of Exchange of Phosphate in Red Blood Cells—Effect of Thyroid Hormones, 679
Bastiansen, Prof. O. : Chemistry and Quantum Chemistry, 158
Basu, T. N., and Bagchi, D. : The Nature of Coal (Physical Methods of Studying the Constitution of Coals), 1438
'Bat Erosion' at Niah Great Caves (Tom Harrisson and Lord Medway), 971
Batchelor, F. R., and others : Penicillin Derivatives of *p*-Aminobenzylpenicillin, 180, *erratum*, 224
  Synthesis of Penicillin—6-Aminopenicillanic Acid in Penicillin Fermentation, 257
Bate-Smith, Dr. E. C. : Chemistry of Condensed Tannins (Formation of Condensed Tannins in Plants), 1169
Bates, Prof. D. R. : Space Research (Experimental Results and Theoretical Considerations relevant to an Understanding of the Atmosphere above 100 km.), 362
Bathyscaphe *F.N.R.S.* III (Dr. F. S. Russell), 1651
Bats and Men : Listening in the Dark, the Acoustic Orientation of (Prof. Donald R. Griffin), *review* by Prof. R. J. Pumphrey, 1554
Battan, Louis J., and others : Grant of 161,800 dollars from the National Science Foundation, to study the physics of clouds and of cloud modification, 1371
Battelle Memorial Institute : New laboratory for research on plutonium, 720
Battey, Edward W. (compiled by) : Instrument Encyclopedia, *review* by Dr. C. A. Taylor, 1768
Bawden, Prof. F. C. : Viruses, Genes and Antigens, *review*, 636
Bawden, Prof. F. C., and Kleczkowski, A. : Photoreactivation of Nucleic Acid from Tobacco Mosaic Virus, 503
Bawn, Prof. C. E. H. : Polymer Chemistry, *review*, 637
Bayley, Dr. F. J. : An Introduction to Fluid Dynamics, *review* by J. L. Stollery, 421
Bayley, H. G. : Gelatin as a Photo-elastic material, 1757
Bayman, B. : Problems of Collective Motion in Physics (The Bohr-Mottelson Explanation of the 'Energy-Gaps' found in Nuclei), 866
B.B.C. : Appointment of C. L. Boltz as Science Correspondent in the News Division, 1231
  Annual Grant of £5,000 for three years to the Council for Nature, for the establishment of an Intelligence Unit, 1231
  Reith Lectures (Prof. A. C. B. Lovell), *review* by Dr. R. A. Lyttleton, 1624
Beacon, Seward E. : Explosion of Transition Metal Co-ordination Compounds, 38
Beadle, B. E. : Hypersonic Flow, 1095
Beale, Dr. G. H. : Elected a Fellow of the Royal Society, 860

Beam, Dr. Walter R. : Appointed head of the Department of Electrical Engineering at Rensselaer Polytechnic Institute, Troy, N.Y., 1164

Bean Endocarp : Effects of Auxins on Membrane Permeability and Pectic Substances in (J. A. Sacher and K. T. Glasziou), 757

Bean (Broad) Seeds : Effect of Light on Maturing (Dr. G. R. Lane and R. D. Butler), 1063

Beans (Black), *Phaseolus vulgaris* : Purification of a Toxic Phytohaemagglutinin from (Dr. Werner G. Jaffé and Karl Gaede), 1329

Bear Island Cod—Migrations and Movements (G. C. Trout), 1100

Beardmore, Dr. J. A. (Cooch, Dr. F. G., and) : Assortative Mating and Reciprocal Difference in the Blue–Snow Goose Complex, 1833

Beardslee, Prof. David C., and Wertheimer, Prof. Michael (selected and edited by) : Readings in Perception, *review* by Prof. R. W. Pickford, 1625

Beare, Prof. W. : Speaking on the motion 'That the Education of our Future Rulers should be primarily in the Sciences rather than the Humanities', 1235

Beattie, J. M., and others (edited by) : Trace Elements—Proceedings of the Conference held at the Ohio Agricultural Experiment Station, 1957, *review* by Dr. E. J. Hewitt, 1009

Beatty, Iva M., and Magrath, Dr. D. I. : Biochemistry of Lombricine—Synthesis of DL- and L-Lombricine, 591

Beatty, Iva, M., and others : Biochemistry of Lombricine—Occurrence of D-Serine in Lombricine, 591

Beberman, Prof. Max : An Emerging Programme of Secondary School Mathematics (Inglis Lecture for 1958), 1366

Beck, M. T. : Co-ordination Chemistry (Work on Catalysis in Hungary), 1785

Beck, Prof. P. A., and others : Low-temperature Specific Heats of Body-centred Cubic Chromium–Iron and Chromium–Manganese Alloys, 315

Becker, E. L., and others : Enzymic Nature of the Serum Globulin Permeability Factor, 1264

Beckett, Prof. J. C. : Queen's, a Short History of Queen's College, Belfast, and the Queen's University of Belfast, 1501

Beddoe, J. E. : Appointed to the Council of the Water Research Association, 1500

Bedford, A. W. : Awarded the R. P. Alston Medal of the Royal Aeronautical Society, 1648

Bedson, H. S., and Farmer, T. H. : Detection of Meprobamate on Paper Chromatograms, 43

Beecher, E. R. : Museum Treatment of Weakened Fabrics, 1501

Beekeeping (Old-time) : Exhibition of (Museum of English Rural Life, Reading), 1782

Beers, jun., Dr. Roland F. : Inhibition of Polynucleotide Phosphorylase by Degraded Ribonucleic Acid—its Reversal by various Agents, 1335

Beersheba : From Dan to—Excavations in North and South Palestine, *review* by Peter J. Parr, 951

Beet (Wild), *Beta patellaris* Moq., as Indicator : Testing Populations of Beet Eelworm, *Heterodera schachtii* Schmidt, for Resistance-breaking Biotypes, using the (Audrey M. Shepherd). 1141

Beet Eelworm, *Heterodera schachtii* Schmidt : Testing Populations of, for Resistance-breaking Biotypes, using the Wild Beet (*Beta patellaris* Moq.) as Indicator (Audrey M. Shepherd), 1141

Beetles : British Water (Prof. Frank Balfour-Browne), Vol. 3, *review* by Dorothy J. Jackson, 1420
  Proepithelial Regeneration in the Midgut of (A. Ameen and Dr. S. A. Shafiq), 913

Beevers, Dr. R. B. : Relaxation Processes, 583

Beginning of the 'Space Age' : The Universe at the (Dr. R. A. Lyttleton), 1019

Behaviour : Ciba Foundation Symposium on the Neurological Basis of (edited by G. E. W. Wolstenholme and Cecilia M. O'Connor), (in commemoration of Sir Charles Sherrington, 1857-1952), *review* by Dr. P. B. Bradley, 954
  Neurophysiology of, *review* by Dr. P. B. Bradley, 954

Behaviour of Dicobalt Octacarbonyl at Elevated Temperature and Carbon Monoxide Pressure (Sol Metlin, Irving Wender and Heinz W. Sternberg), 457

Behaviour in a Group of Small Animals : A Photographic Method for Recording Activity and (Dr. D. K. Edwards), 625

Behaviour of Invertebrates : An Introduction to the (Dr. J. D. Carthy), *review* by Dr. G. A. Horridge, 4

Behaviour of Sacculinized Shore Crabs (*Carcinus maenas* Pennent), (Erik Rasmussen), 479

Behaviour of Vacuum Arc Cathode Spots : An Effect of Oxide Layers on the (H. Wroe and R. H. Alderson), 1544

Behaviour (Chromatographic), of Human Albumin labelled with Iodine-131 (Dr. S. Cohen), 393

Behaviour (Etch), of Jacobsite with Different Cell Dimensions : Variation in (Dr. Supriya Roy), 1256

Behaviour (Injury-feigning), of Wood-Pigeons (C. S. Payne), 1643

Behaviour (Psychomotor), and Delinquency : Association between (H. S. Anthony), 343

Behaviour and Psychological Man (Prof. Edward Chace Tolman), *review* by Prof. John Cohen, 781

Being a Technologist : On (Prof. D. G. Christopherson), 1780

Beit Memorial Trust : Report for 1958-59, 1569
  Election of Sir Francis Glyn as a Trustee and honorary treasurer, 1569
  Appointment of Dr. Honor B. Fell to the Advisory Board, 1569
  Appointment of Sir Roy Cameron as secretary, 1569
  Elections to Fellowships, 1569

Bekku, Dr. S. : *Obituary*, 1017

Belford, Dr. D. S., and others : Copper–Cellulose Complexes, 988

Belkhode, M. L. (Nath, Prof. M. C., and) : Glucose-*cyclo*-Acetoacetate as a Precursor of Ascorbic Acid in Germinating Green Gram, 1258

Bell, Dr. D. A. : Physics for the Electrical Engineer, *review*, 707

Bell, E. J., and others : Parasitology (The *in vitro* Culture of Strigeid Metacercariae to the Sexually Mature Adult Fluke), 1506

Bell, Dr. F. R., and Williams, H. L. : Threshold Values for Taste in Monozygotic Twin Calves, 345

Bell, Dr. G. D. H. : Wheat Genetics, 26
  Obituary of Dr. Herbert Hunter, 1016

Bell, J. D., and others : 'Ring Angels' over South-East England, 1759

Bell, P. R. : Experimental Approaches to the Problems of Growth and Form in Plants (Experimental Investigation of the Pteridophyte Life-Cycle), 585

Bell Telephone Laboratories : Election of Dr. James B. Fisk as president, 220
  Election of Dr. M. J. Kelly as chairman of the board of directors, 220
  Appointment of Estill I. Green as executive vice-president, 220
  Appointment of Prof. J. W. Tukey as assistant director of research in communication principles, 648
  New laboratory at Holmdel, New Jersey, 1641

Bell Telephone Laboratories (Members of the Technical Staff of) : Transistor Technology, Vol. I (edited by H. E. Bridgers, J. H. Scaff and J. N. Shive), Vol. 2 (edited by F. J. Biondi), *review* by Dr. J. R. Tillman, 72
  Vol. 3 (edited by F. J. Biondi), *review* by Dr. J. R. Tillman, 1557

Bell Telephone Laboratories (Western Electric Company and the) : Synthetic Quartz Crystals, 294

Bell Telephone Laboratories and the American Institute of Electrical Engineers : Establishment of the Kelly Award, 510

Belson, W. A. : Matching and Prediction in the Social Sciences, 772

Bendall, J. R. : Reflexions on the Motility of Muscle, *review*, 278

Bendat, Dr. Julius S. : Principles and Applications of Random Noise Theory, *review* by R. A. King, 353

Bengtsson, Prof. Lars Ph. : Recovery of Injected Progesterone and its relation to the Onset of Human Labour, 405

Benjamin, P. (Weaver, C., and) : Interfacial Phenomena (Adhesion of Evaporated Metal Films to Glass), 1098

Benkö, A., and others : Changes produced in Serum Lipoproteins of Dogs by Cellulose containing Methyl Groups, 1119

Bennet, J. A. : Interfacial Phenomena (Electrical Resistivity of a Gold Film being deposited on Alumina or a Substrate of Bismuth Oxide on Alumina), 1097

Bennett, Dr. G. M. : *Obituary* by Dr. A. D. Mitchell, 717

Bennett, M. A. E., and others : Penicillin as an Antigen, 468

Bennett, M. C., and Cope, F. W. : Nuclear Fusion and Non-Fusion in *Theobroma cacao* L., 1540

Bennett, Dr. Winifred, and Garrison, Dr. Warren M. : Production of Amide Groups and Ammonia in the Radiolysis of Aqueous Solutions of Protein, 889

Bennewitz, Dr. H. G. : Chemistry and Quantum Chemistry, 159

Benney, W. E., and others : Changes in the Group *A* Antigen in a Case of Leukaemia, 892

Bennhold, H., and others : Albumin labelled with Iodine-131 in an Analbuminaemic Subject, 606

Bensch, Klaus G., and others : Phagocytosis and Cell Division, 476
  Variability of Content of Deoxyribonucleic Acid in *L*-strain Fibroblasts, 1818

Benson, A. (Lemberg, Prof. R., and) : Incorporation of Radioactive Iron into Haematin *a*, 678

Bentley, H. R., and Berry, E. G. N. (edited by) : The Constituents of Tobacco Smoke—an Annotated Bibliography, 1434

Bentley, O. G., and others (edited by) : Trace Elements—Proceedings of the Conference held at the Ohio Agricultural Experiment Station, 1957, *review* by Dr. E. J. Hewitt, 1009

Bentzon, M. W., and others : Synthesis of Deoxyribonucleic Acid during the Division Cycle of Bacteria, 1207

Benua, R. S., and others : Incorporation of 5-Iodouracil labelled with Iodine-131 into the Deoxyribonucleic Acid of Human Leukaemic Leucocytes following *in vivo* Administration of 5-Iododeoxyuridine labelled with Iodine-131, 1686

Benzene Hexachloride : Metabolism of, by Resistant Houseflies *Musca domestica* (Dr. F. R. Bradbury and H. Standen), 983

Benzenoid Compounds : Detection and Estimation of, by Chromatography (P. Moss and A. J. Thomas), 1611

5-Benzylidenerhodanine : Pharmacological and Toxicological Properties of (Salah A. Tawab, Prof. Ahmed Mustafa and A. F. A. Mawgoud Shalaby), 607

Bergel, Prof. F. : Elected a Fellow of the Royal Society, 860

Berger, Gaston : Elected a Fellow of the International Academy of Management, 1719

Berger, S., and others : Effect of Protein-free Diet on the Vitamin A Storage in the Rat Liver, 1597

Berggren, Lennart, and others : Bacterial and Testicular Hyaluronidase, 265

Bergmann, Prof. F. (Lachmann, Dr. J., and) : Dissociated Nystagmus in the Rabbit, 1065

Berkowitz, N. : The Nature of Coal (Decomposition and Diffusion Processes in Coal Pyrolysis), 1439

Berman, H., and Kibler, H. H. : Effect of Clipping the Coat on the Thermoregulatory Reactions of Dairy Heifers, 606

Bernal, Prof. J. D. : A Geometrical Approach to the Study of Liquids, 141

Berrie, Dr. Geoffrey K. : Mitosis in the Microspore of *Encephalartos barteri* Carruth., 834

Berry, E. G. N. (edited by Bentley, H. R., and) : The Constituents of Tobacco Smoke—an Annotated Bibliography, 1434

Berry, W. G., and others : Polynomial Representation of Steam Tables, 598

Berry and Dedrick : Reactivation of Heat-inactivated Poxviruses—a General Phenomenon which includes the Fibroma–Myxoma Virus Transformation of (Prof. Frank Fenner, I. H. Holmes, Dr. W. K. Joklik and Gwendolyn M. Woodroofe), 1340

Berson, F. A. : Antarctic Meteorology, 1504

Beryllium : Electrolytic Deposition of (Dr. I. A. Menzies, D. L. Hill and L. W. Owen), 816

Berz, I. : Effects of Arc Stage of Electrical Discharge on Ignition of Inflammable Gas, 669

Bessemer Gold Medal for 1959 of the Iron and Steel Institute awarded to Prof. Bo Kalling, 930

Besserer, C. W. : Missile Engineering Handbook, *review*, 210

Bestor, Prof. Arthur : Education in the Age of Science, 1436

Besznyák, I., and others : Effect of 1,6-Di-(2-Bromoethylamino)-1,6-Dideoxy-D-Mannitol Dihydrobromide on Tumours of Laboratory Animals, 395

β-Aminoethyl*iso*thiouronium Dibromide: Anti-Thyroid Action of, in Rats (John Osmer, Dr. Robert B. Jennings and Dr. Robert M. Dowben), 470

β-Aminoethylthiosulphuric Acid : Protective Effect of, against Ionizing Radiation (Bo Holmberg and Bo Sörbo), 832

β-Amino-*iso*butyric Acid : Urinary Excretion of, in Eskimo and Indian Populations of Alaska (Dr. A. C. Allison, Dr. B. S. Blumberg and Dr. S. M. Gartler), 118

β-Diketones : Metal–Oxygen Stretching Frequencies in the Metal Chelate Compounds of (Kazuo Nakamoto, Paul J. McCarthy and Arthur E. Martell), 459
β-Globulin Polymorphism and Early Foetal Mortality in Cattle (Dr. G. C. Ashton), 404
β-Glycine : Crystal Structure of (Dr. Yoichi Iitaka), 390
β-Hydroxybutyrate Injections : Effect of, on the Pancreatic Activity of Guinea Pigs (Dr. H. D. Brahmachari and Mahendra Kumar), 51
β-Oxidation of Aryloxy-alkylcarboxylic Acids by *Nocardia opaca* : Effect of Substitution in the Side-Chain on (D. M. Webley, R. B. Duff and V. C. Farmer), 748
β-Polymorphs of Uranium and Thorium Disilicides (A. Brown and J. J. Norreys), 673
β-Type Interlamellar Sorption Complexes (F. Aragón, J. Cano Ruiz and Dr. D. M. C. MacEwan), 740
β-, γ, and δ-Tocopherols (Pure α-,), in the Growing Chick : Relative Rates of Liver Storage of (T. W. Griffiths), 1061
Beta patellaris Moq. (Wild Beet), as Indicator : Testing Populations of Beet Eelworm, *Heterodera schachtii* Schmidt, for Resistance-breaking Biotypes, using the (Audrey M. Shepherd), 1141
Beth, Dr. Kurt (Thimann, Prof. Kenneth V., and) : Action of Auxins on *Acetabularia* and the Effect of Enucleation, 946
Bett, Dr. W. R. : Amphetamine Psychosis, *review*, 639
  The Haffkine Institute, Bombay—Diamond Jubilee, 725
  Obituary of Cyril Barnard, 1159
Betteridge, Dr. W. : Appointed superintendent of the Platinum Metals Research Laboratory of the Mond Nickel Development and Research Department, Acton, 1432 ; work of, 1432
Beutler, Dr. Ernest, and others : Incidence of the Erythrocytic Defect associated with Drug-Sensitivity among Oriental Subjects, 684
Beverage Technology and Distribution, 1936-56 : Bibliography of Food—a Select International Bibliography of Nutrition, Food and (E. Allan Baker and D. J. Foskett), *review* by Dr. Magnus Pyke, 351, 582
Beveridge, Gordon S. G., and Denbigh, Prof. Kenneth G. : High-Temperature Oxidation of Zinc Sulphide, 106
Beverley, Dr. J. K. A.: Congenital Transmission of Toxoplasmosis through Successive Generations of Mice, 1348
Beverton, R. J. H. : Appointed deputy director of fisheries research in the Ministry of Agriculture, Fisheries and Food, 1568 ; work of, 1568
Bhagavantam, Dr. S. : The Indian Institute of Science, Bangalore—Golden Jubilee, 644
Bharadwaj, Dr. T. P. (Love, Dr. Robert, and) : Two Types of Ribonucleoprotein in the Nucleolus of Mammalian Cells, 1453
Bhattacharya, Dr. Gangagobinda : Influence of Ions on the Uptake of Glucose and on the Effect of Insulin on it by Rat Diaphragm, 324
Bhattacharya, Dr. S. K. : Amperometric Determination of Sulphydryl Content of Blood and Tissues, 1327
BHC : Metabolism of, by Resistant Houseflies *Musca domestica* (Dr. F. R. Bradbury and H. Standen), 983
Bhide, Dr. N. K., and Aimen, R.A. : Pharmacology of a Tranquillizing Principle in *Paspalum scrobiculatum* Grain, 1735
Bhowmick, J. N. : The Nature of Coal (Aliphatic Hydrogen in Coal), 1439
Bibliographies on Geology, 932
Bibliography on the Chemistry of Tobacco Smoke, 1434
Bibliography on the Effects of Ionizing Radiations on Plants, 1896-1955 (Arnold H. Sparrow, John P. Binnington and Virginia Pond), *review* by Dr. Alma Howard, 639
Bibliography of Food—a Select International Bibliography of Nutrition, Food and Beverage Technology and Distribution, 1936-56 (E. Alan Baker and D. J. Foskett), *review* by Dr. Magnus Pyke, 351, 582
Bibliography of Natural History, Society for the : Election of Officers, 1094
Bibliography (Classified), of Gerontology and Geriatrics, Supplement I. 1949-1955 (Dr. Nathan W. Shock), *review* by Prof. P. L. Krohn, 777
Bibliography (International), of Nutrition, Food and Beverage Technology and Distribution, 1936-56 : Bibliography of Food—a Select (E. Alan Baker and D. J. Foskett), *review* by Dr. Magnus Pyke, 351, 582
Bicentenary of the publication of the tenth edition of the 'Systema Naturae' by Linnaeus : Centenary of the formulation of the Theory of Evolution by Charles Darwin and Alfred Russel Wallace and the (Congress in Singapore to celebrate the), 723
Bicentenary of the Royal Botanic Gardens, Kew (Dr. W. B. Turrill), 1488
Bicentenary of the Royal Botanic Gardens, Kew : Vistas in Botany—a Volume in honour of the (edited by Dr. W. B. Turrill), *review* by Prof. W. H. Pearsall, 1484
Bickis, I. J. (Quastel, Prof. J. H., and) : Metabolism of Normal Tissues and Neoplasms *in vitro*, 281
Biddiscombe, E. F. (Scurfield, Dr. G., and) : Effects of Gibberellic Acid on Winter Pasture Production, 1196
Biggs, Dr. R. : Clinical Haematology in Medical Practice, *review*, 1151
Bignall, J. R. (edited by) : Carcinoma of the Lung, *review* by Dr. L. Foulds, 955
Bigsby Medal for 1959 of the Geological Society awarded to Prof. B. C. King, 364
Bijnaner Itihas (A History of Science), (Sri Samarendranath Sen), Vol. 2 (in Bengali), *review* by Dr. F. R. Allchin, 1353
Bile (Rabbit) : Ester Sulphate Pattern of (Dr. Harry Boström and Anders Vestermark), 1593
Biliary Obstruction (Acute) : Determination of Transaminase Activity in Dogs' Serum and Lymph after Hepatic Damage due to (Dr. P. Braun, Dr. M. Papp and Dr. I. Horváth), 48
Biligirirangan Hills, Mysore State, India : Trap-Shotten Rock from the (Prof. C. S. Pichamuthu), 483
Bilirubin Conjugation *in vitro* : Factors affecting the Rate of (Dr. E. Talafant and J. Továrek), 111
Bilirubin Metabolism in the Foetus (Dr. Rudi Schmid, Sur Buckingham, Gloria A. Mendilla and Lydia Hammaker), 1823
Bill, Mrs. M. C. (Roux, Dr. David G., and) : Mechanism of Formation of Anthocyanidins from Leucoanthocyani(di)ns, 42
Binaghi, R. (Halpern, Dr. B. N., and) : Selective Permeability of Living Tissues to Carbonic Acid, 1397
Binding of Water in Ferric Hydrate (Prof. O. Glemser), 1476
Binding of Water in some Hydroxides and Hydrous Oxides (Structure of some Hydroxides and Hydrous Oxides), (Prof. O. Glemser), 943
Binnington, John P., and others : Bibliography on the Effects of Ionizing Radiations on Plants, 1895-1955, *review* by Dr. Alma Howard, 639
Bioassay of Sheep Anterior Pituitary Glands (Dr. D. R. Lamond, H. M. Radford and A. L. Wallace), 1597
Bio-Astronautics : Armed Forces—National Research Council Committee on, to advice on the biological or medical aspects of space exploration, 651
Biochemical Analysis, *review* by Dr. I. D. P. Wootton, 779
  Methods of (edited by Prof. David Glick), Vol. 6, *review* by Dr. I. D. P. Wootton, 779
Biochemical Differentiation of Group *A* and 'Human C' *Streptococci* (R. W. Henningson), 182
Biochemical Engineering : Postgraduate Course in (University College, London), 933
Biochemical Heterogeneity of the Ribonucleic Acid synthesized by *Escherichia coli B* after Irradiation with Ultra-violet Light (Kenshi Suzuki and Jôji Ono), 395
Biochemical Society : Election of Sir Henry Dale to honorary membership, 18
  Symposium on Metals and Enzyme Activity, Leeds, 1956 (organized and edited by E. M. Crook), *review* by Dr. O. T. G. Jones, 968
Biochemical and Microbiological Technology and Engineering, Journal of, Vol. 1, No. 1, 1367
Biochemie : Radioaktive Isotope in der (Prof. Engelbert Broda), *review* by Dr. H. R. V. Arnstein, 1149
Biochemistry at the Royal College of Surgeons, 579
Biochemistry : Advances in Enzymology and related Subjects of (edited by F. F. Nord), Vol. 20, *review* by Dr. Edwin C. Webb, 961
  Annual Review of (edited by J. Murray Luck, in association with Frank W. Allen and Gordon Mackinney), Vol. 27, *review* by Prof. F. G. Young, 961
  Colorimetry in, *review* by Dr. N. R. Lawrie, 207
  Fourth International Congress of (Proceedings to be published by the Pergamon Press), 510
  General (Prof. Joseph S. Fruton and Prof. Sofia Simmonds), second edition, *review* by D. H. Northcote, 968
  New, *reviewed* by Prof. F. G. Young, 961
  Radioactive Isotopes in, *review* by Dr. H. R. V. Arnstein, 1149
  Textbook of (Prof. Benjamin Harrow and Prof. Abraham Mazur), seventh edition, *review* by Prof. F. G. Young, 967
Biochemistry, International Union of : Symposium on Haematin Enzymes, 1571
Biochemistry of Lombricine—Occurrence of D-Serine in Lombricine (Iva M. Beatty, Dr. D. I. Magrath and Prof. A. H. Ennor), 591 ; Synthesis of DL- and L-Lombricine (Iva M. Beatty and Dr. D. I. Magrath), 591
Biochemistry in Medicine, *review* by Prof. J. N. Davidson, 5
Biochemistry (Physical), at Canberra, 151
Biodynamics : Basic (E. J. Kempf), 933
Biographical Approach to John Dalton (Frank Greenaway), *review* by Prof. J. R. Partington, 1765
Biological Activity of L-Tryptophan Esters (Dr. Giulio C. Perri, Louis Kaplan and C. Chester Stock), 116
Biological Aspects of the Transmission of Disease—Report of the Institute of Biology Symposium (edited by C. Horton-Smith), *review* by Dr. C. W. Dixon, 1221
Biological Effects of Space Flight, 651
Biological Examination (Bacteriological, Chemical and), of the London Waters for the Years 1955-56 : Thirty-seventh Report on the Results of the (E. Windle Taylor), 798
Biological Fibres : Clay Minerals and (X-Ray Analysis Group of the Institute of Physics Conference on), 1024
Biological Fluids : Direct Determination of Drug Concentrations in, by Polarography (Dr. P. O. Kane), 1674
Biological Information—Theory and Practice, *review* by Dr. Roy Markham, 1292
Biological Origin of Manganese-rich Deposits of the Sea Floor (John W. Graham and Susan C. Cooper), 1050
Biological Properties of the S-(Methylcarbamyl) Methyl 0,0-Dimethyl-Dithiophosphate : Mode of Action and (R. Santi and P. de Pietri-Tonelli), 398
Biological Replication of Macromolecules (edited by F. K. Sanders), *review* by Dr. Roy Markham, 1292
Biological Research : A Century of (Illinois Natural History Survey, Bulletin, Vol. 27), 1233
Biological Sciences in the United States : Nuclear Training in the, 1091
Biological Term 'Pheromone' : The Proposed (H. S. Micklem), 1835 ; (Dr. P. Karlson and Prof. M. Lüscher), 1835
Biological Ultrastructure (Prof. Arne Engström and Dr. J. B. Finean), *review* by Dr. H. E. Huxley, 956
Biologically Active Substances : 'Pheromones', a New Term for a Class of (Dr. P. Karlson and Prof. M. Lüscher), 55
Biologische und Serologische Eigenschaften der Bartonellen : Morphologische, (Dr. Reinhard Wigand), *review* by Dr. A. Lwoff, 207
Biology : Electrical Techniques in Medicine and (American Institute of Electrical Engineers, the Institute of Radio Engineers and the Instrument Society of America twelfth Annual Conference on), 1434
  The Physical Foundation of (Prof. Walter M. Elsasser), *review* by Dr. W. Grey Walter, 955
  Polysaccharides in—Transactions of the Second Josiah Macy, Jr. Foundation Conference, Princeton, 1956 (edited by Dr. George F. Springer), *review* by Prof. M. Stacey, 1219
  Twelfth Brookhaven Symposium in (Structure and Function of Genetic Elements), 1094
Biology (Experimental), Society for : Symposia No. 12, The Biological Replication of Macromolecules (edited by F. K. Sanders), *review* by Dr. Roy Markham, 1292
Biology (Field) : A. Guide to (John Sankey), *review* by W. H. Dowdeswell, 1081
Biology (Marine), especially Fisheries : Shorewards Upslope of the Layer of Minimum Oxygen off Bombay—its influence on (Dr. J. N. Carruthers, S. S. Gogate, J. R. Naidu and T. Laevastu), 1084
Biology (Marine), or Oceanography : Grants for research in (Challenger Society), 1368
Biology (Molecular), Journal of, Vol. 1, No. 1, 1641
Biology (Quantitative) : Twenty-fourth Cold Spring Harbor Symposium on (Genetics and 20th Century Mendelism), 934
  Cold Spring Harbor Symposia on, Vol. 22, Population Studies—Animal Ecology and Demography, *review* by Dr. A. Milne, 1220

Biology of Hair Growth (edited by William Montagna and Richard A. Ellis), *review* by Dr. F. W. Dry, 851
Biology, Institute of : Symposium on the Biological Aspects of the Transmission of Disease (edited by C. Horton-Smith), *review* by Dr. C. W. Dixon, 1221
Biology, Institute of (Parasitology Group) : Spring Meeting at the University of Edinburgh (Discussion on Parasitology), 438, 1506
  Discussion on the Chemotherapy of Parasitic Diseases, 1029
Biology (Experimental) : International Symposium on, in commemoration of Lazzaro Spallanzani, 582
Biology (Human), Society for the Study of : Symposium on Natural Selection in Man, 159
Biology (*Radiation*), *International Journal of*, Vol. I, No. 1, 1020
Biology Courses (College), on Television, 649
Biondi, F. J. (edited by) : Transistor Technology, Vol. 2, *review* by Dr. J. R. Tillman, 72 ; Vol. 3, *review* by Dr. J. R. Tillman, 1557
Biosynthesis of Cell Constituents from C_2-Compounds—Formation of Malate from Glycollate by *Pseudomonas ovalis* Chester (Dr. H. L. Kornberg and A. M. Gotto), 1791 ; Metabolism of Glycine by a Pseudomonad (A. G. Callely and Dr. S. Dagley), 1793 ; Formation of Glycerate from Oxalate by *Pseudomonas oxalaticus* (OXI) grown in Oxalate (J. R. Quayle and Dr. D. B. Keech), 1794
Biosynthesis in Chick Liver : Vitamin B_{12} and (Vitamin B_{12} and Protein Biosynthesis), (Dr. M. J. Fraser and Dr. E. S. Holdsworth), 519
Biosynthesis of Ovalbumin (Prof. D. V. Siva Sankar and Henry W. Theis), 1057
Biosynthesis in Rat Liver : Vitamin B_{12} and (Vitamin B_{12} and Protein Biosynthesis), (Dr. H. R. V. Arnstein and Dr. J. L. Simkin), 523
Biosynthesis of Rubber (Dr. J. A. Gascoigne and Patricia Jones), 819
Biosynthesis and Constitution of Lignin (Prof. Karl Freudenberg), 1152
Biosynthesis (Protein) : Vitamin B_{12} and—Vitamin B_{12} and Biosynthesis in Chick Liver (Dr. M. J. Fraser and Dr. E. S. Holdsworth), 519 ; Vitamin B_{12} and Biosynthesis in Rat Liver (Dr. H. R. V. Arnstein and Dr. J. L. Simkin), 523
Biosynthesis (Purine) : Feedback Control of, by Purine Ribonucleotides (Dr. James B. Wyngaarden and Doris M. Ashton), 747
Biosynthesis (Trehalose), in the Locust : Site and Mode of (D. J. Candy and Dr. B. A. Kilby), 1594
Biotypes (Resistance-breaking) : Testing Populations of Beet Eelworm, *Heterodera schachtii* Schmidt, for, using the Wild Beet (*Beta patellaris* Moq.) as Indicator (Audrey M. Shepherd), 1141
Birch, H. F. : Simultaneous Decomposition Processes in Soils, 1415
Bird, Junius, and others : Radiocarbon Measurements on Samples of Known Age, 1582
Bird (Oliver) Prize for 1958 awarded to Prof. M. C. Shelesnyak, 1643
Bird Migration, Vol. 1, No. 1 (British Trust for Ornithology), 436
Birds : The Folklore of (Edward A. Armstrong), *review* by M. C. Burkitt, 1422
  Fossil (Dr. W. E. Swinton), *review*, 73
  The Work Output of Animals—Flight by, and by Man-power (Dr. D. R. Wilkie), 1515
Birds of Cyprus (Dr. David A. Bannerman and W. Mary Bannerman), *review* by Sir Landsborough Thomson, 967
Birds of Poland (Ptaki Ziem Polskich), (Jan Sokolowski), Tom 2, *review* by B. Nowosielski-Slepowron, 73
Birds of Stowe : An Account of the (Stowe School), 1718
Birds (Egyptian) : Systematic and Experimental Studies on Protozoal Blood Parasites of (Dr. A. H. Helmy Mohammed), *review* by Dr. Elizabeth U. Canning, 1081
Birds (Marine) : Salt Excretion in (Dr. L. Harrison Matthews), 202
Birds and Mammals of Canada, 154
Bireska, Mme. : Phosphates and Organic Substances in Nitrogen Deficiency, 513
Birkbeck College, London : Title of reader in crystallography in the University of London conferred on Dr. C. H. Carlisle, 794
Birmingham College of Technology : Conference on Electronic Digital Computers and their Industrial Applications, 154
Birth of Nigeria's University (Dr. Kenneth Mellanby), *review* by Sir Eric Ashby, 137
Birth of the Steamboat (H. Philip Spratt), *review* by A. W. Jones, 1626
Bishop, Dr. Ann : Elected a Fellow of the Royal Society, 860
  Chemotherapy of Parasitic Diseases (Resistance to Drugs in Parasitic Protozoa), 1029
Bishop, Dr. Alan W., and Henkel, D. J. : The Measurement of Soil Properties in the Triaxial Test, *review* by Thomas Whitaker, 1151
Bishop, J. S., and others : Mechanism of Action of Insulin, 1123
Bishop, Dr. M. W. H. (Lovelock, Dr. J. E., and) : Prevention of Freezing Damage to Living Cells by Dimethyl Sulphoxide, 1394
Bishop, Dr. P. M. F., and others : A Presumptive Human *XXY*/*XX* Mosaic, 1030
Bishop, Prof. R. E. D. : Development in Photoelasticity—Commemoration at University College, London, 1495
Biswas, B. B., and Sen, S. P. : Relationship between Auxins and Nucleic Acid Synthesis in Coleoptile Tissues, 1824
Bivalent Metal Ions : Reversal of Antibiotic Action of Cycloheximide (Actidione) by (M. Blumauerová and J. Stárka), 261
Bjerknes, Prof. J. : Awarded the International Meteorological Organization Prize of the World Meteorological Organization, 1567 ; work of, 1567
Bjerrum, Prof. J., and co-workers : Co-ordination Chemistry (Kinetics of the Hydrolysis of Chromic Complexes), 1784
Bjerrum, Prof. Niels : *Obituary* by Prof. J. R. Partington, 290
Björnerstedt, Rolf, and others : Bone and Radiostrontium, *review* by J. Vennart, 965
Black, G., and others : Polynomial Representation of Steam Tables, 598
Black, Maurice : Awarded a research grant by the Leverhulme Trust, 1499
Black Beans (*Phaseolus vulgaris*) : Purification of a Toxic Phytohaemagglutinin from (Dr. Werner G. Jaffé and Karl Gaede), 1329
Black Fens : The (A. K. Astbury), *review* by Dr. M. A. Morgan, 965
Black Sea : Microbiology and Water Circulation in the (A. E. Kriss), 437
Blackall, Dr. William E., and Grieve, Dr. Brian J. : How to Know Western Australian Wildflowers, Part 2, A Key to the Flora of the Temperate Regions of Western Australia, *review* by V. S. Summerhayes, 1628
Blackband, W. T.: Space Research (System for the Recovery of Information from vehicles as far away as the nearer Planets), 363
Blackband, W. T., and others : Deduction of Ionospheric Electron Content from the Faraday Fading of Signals from Artificial Earth Satellites, 1172
Blackbirds : A Study of (Dr. D. W. Snow), *review* by Dr. R. A. Hinde, 1767
Blackcliff and Wyndcliff Forest Nature Reserve (Nature Conservancy), 1650
Blackcoated Worker : The (David Lockwood), *review*, 494
Blackburn, T. H., and others : Assimilation of Ammonia Nitrogen by Rumen Bacteria, 402
Blackett, Prof. P. M. S. : *Obituary* of Prof. Arturo Duperier, 1015
  The British Association Looks Ahead, 1569
Blackie, Dr. M. S., and Gold, Dr. V. : Magnetometric Titration—a New Method of Chemical Analysis, 1804
Blackman, Prof. G. E. : Elected a Fellow of the Royal Society, 860
Blackman, Dr. L. C. F., and others : Metallic Conduction in the Crystal Compounds of Graphite, 454
Blackman, M. : Interfacial Phenomena (Epitaxial Polymorphism of Thallium and Caesium Halides), 1097
Blackwell, B. D. : Awarded the Branch Prize of the Royal Aeronautical Society, 1649
Bladder-Wall in the Rabbit : Absorption of Radioiodine through the (Oskar Andrysek and Ota Schück), 893
Blain, Dr. Isabel : Comments on the Job, 372
Blair, Alberta (Segal, Dr. Stanton, and) : Effect of Salicylate on Muscle Phosphorylase, 1609
Blair, D. T. A., and others : Gas Discharges (Spark, High-frequency and Glow Discharges), 93
Blair, Dr. G. W. Scott : An Equation for the Flow of Blood, Plasma and Serum through Glass Capillaries, 613
Blake, G. M. : Control of Diapause by an 'Internal Clock' in *Anthrenus verbasci* (L.) (Col., Dermestidae), 126
Blakely, J. M., and Mykura, H. : Interfacial Phenomena (Surface Tension of Metallic Interfaces), 1098
Bland, J. A., and Basinski, S. J. : Crystal Symmetry of Struvite (Guanite), 1385
Blanshard, Prof. Brand : Education in the Age of Science, 1437
Blaxter, J. H. S., and others : 'Chloride-Secretory' Cells in the Gills of Teleosts, 1248
Bleakney, Prof. Walker : Elected a member of the United States National Academy of Sciences, 1575
Bleichert, A. (Reichel, Prof. H., and) : Excitation–Contraction Coupling in Heart Muscle, 826
Blindness (Colour-) in Klienfelter's Syndrome (Prof. Curt Stern), 1452
Bloat in Cattle (Dr. M. J. Head), 757
Block, Dr. Richard J. (Werner, Dr. Sidney C., and) : Discrepancy between the Distributions of Iodine in Human Serum when estimated by Iodine-131 and Iodine-127, 406, *erratum*, 722
Block (Ganglionic), and Monoamine Oxidase Inhibitors (Dr. Sheldon B. Gertner), 750
Block and Graft Co-polymers : Stereo-specific Polymers and (Bradford Institute of Technology Course on), 224
Blocking Agents (Neuromuscular), of Short Duration (C. G. Haining, R. G. Johnston and J. M. Smith), 542
Blom, Dr. Erik : A Rare Sperm Abnormality—'Corkscrew-sperms' associated with Sterility in Bulls, 1280
Blood : Carbon Monoxide Content of the, and other Observations on Weddell Seals (Dr. L. G. C. E. Pugh), 74
  5-Hydroxytryptamine in, during Experimental Traumatic Shock in Rats (M. Medaković and I. Spuzić), 1685
  Research on Diseases of the (Lady Tata Memorial Trust Grants, Scholarships and Fellowships for), 581
Blood of Two Full-term New-born Babies with Multiple Malformations : Co-existence of the Embryonic (Third Normal) Haemoglobin Fraction with Erythroblastosis in the (Prof. I. Halbrecht, Ch. Klibanski, and F. Bar Ilan), 327
Blood (Duck), incubated *in vitro* with $NaH^{14}CO_3$: Labelled Keto-Acids in (A. Breccia, A. L. Fantola, G. Giustina and E. Lazzarini), 1328
Blood (Mammalian) : Anticoagulant Action of Fibrin Surfaces on (Dr. A. L. Copley, D. Steichele, M. Spradau and R. S. Thorley), 1683
Blood (Spermatic Vein) : Androgens in the Bovine Testis and (H. R. Lindner), 1605
Blood and Liver Xanthine Dehydrogenase of Rats : Effect of Salicylate on (Emilio Mitidieri and Ottilia R. Affonso), 471
Blood, Plasma and Serum through Glass Capillaries : An Equation for the Flow of (Dr. G. W. Scott Blair), 613
Blood and Serum of Non-immunized and Immunized Animals : Factors Inhibiting and Stimulating Growth of *Mycobacteria* in the (J. Hubáček and I. Málek), 187
Blood and Tissues : Amperometric Determination of Sulphydryl Content of (Dr. S. K. Bhattacharya), 1327
Blood-clotting Activity of the Venom of *Bothrops jararaca* (Dr. Olga B. Henriques, Dr. Fajga R. Mandelbaum and Dr. S. B. Henriques), 114
Blood Cells (Red) : Rate of Exchange of Phosphate in—Effect of Thyroid Hormones (A. M. Ermans and Prof. P. A. Bastenie), 679
Blood-Group Investigation on Central Kalahari Bushmen (Dr. J. S. Weiner and Dr. A. Zoutendyk), 843
Blood Group Phenotype K–, k–, Kp(a–b–) : A Further Example of the Kell (Hiroko Kaita, Marion Lewis, Dr. Bruce Chown and Eileen Gard), 1586
Blood Groups in Man (Dr. R. R. Race and Dr. Ruth Sanger), third edition, *review* by Dr. F. Stratton, 280
Blood Parasites (Protozoal), of Egyptian Birds: Systematic and Experimental Studies on (Dr. A. H. Helmy Mohammed), *review* by Dr. Elizabeth U. Canning, 1081
Blood Platelets (Human) : Taurine in (Julian Frendo, Aleksander Koj and Jan M. Zgliczyński), 685
Blood Sample (Human), belonging to Group AB : A Rare Variant of B in a (Dr. J. Moullec and Dr. P. Le Chevrel), 1733
Blood Smears : Feulgen–Naphthoic Acid Hydrazide Reaction applied to (Dr. R. K. Archer), 820
Blood Supply of Bone : Iodine-131 Clearance-rates as an Indication of the (Dr. P. G. Laing and Dr. Albert B. Ferguson, jun.), 1595
'Blood Thromboplastin' : Arginine Esterase Activity of (Phyllis M. Arscott, J. L. Koppel and John H. Olwin), 753
Blow-hole Theory : Simulation of Lunar Craters—a (Dr. A. G. Gaydon and R. C. M. Learner), 37

Blue Tetrazolium : Photochemical Reduction of, by Isolated Chloroplasts (John J. Taylor and Prof. Meyer Chessin), 626
Blue–Snow Goose Complex : Assortative Mating and Reciprocal Difference in the (Dr. F. G. Cooch and Dr. J. A. Beardmore), 1833
Blumauerová, M., and Stárka, J. : Reversal of Antibiotic Action of Cycloheximide (Actidione) by Bivalent Metal Ions, 261
Blumberg, Dr. B. S., and others : Urinary Excretion of β-Amino-*iso*butyric Acid in Eskimo and Indian Populations of Alaska, 118
Blyth, Dr. F. G. H. : Appointed reader in engineering geology at the Imperial College of Science and Technology, 1571
Boag, Dr. J. W., and Müller, A. : Changes in the Electron Spin Resonance Spectrum of Glycine with Increasing Doses of Radiation, 831
  Electron Spin Resonance in Irradiated Deoxyribonucleic Acid, 831
Boag, Dr. J. W. (Dewey, D. L., and) : Modification of the Oxygen Effect when Bacteria are given Large Pulses of Radiation, 1450
Boas, Prof. Marie : Robert Boyle and Seventeenth-Century Chemistry, *review* by Dr. R. E. W. Maddison, 850
Bodanszky, Dr. Miklos, and du Vigneaud, Prof. Vincent : Synthesis of Oxytocin by the Nitrophenyl Ester Method, 1324
Boddington, Lewis : Appointed to the rank of chief scientific officer, and director-general of Aircraft Research and Development (R.A.F.), 1231 ; work of, 1231
Boden, Brian P., and others : Electrical Response to Illumination of the Euphausiid Crustacean Eye, 1820
Bodenheimer, Prof. F. S. : Animal Ecology To-day, *review* by Dr. A. Milne, 1220
Body, R. A. F., and others : Reaction of some Silicates with Chelating Agents, 99, *erratum*, 1719
Body (Weight of), in Rats : Effect of Reduction of Stimulation on Consumption of Food, Intake of Water and (Dr. Karl Weiss and Harry M. B. Hurwitz), 344
Body Fluids : Rapid Specific Method for Determination of Aldosaccharides in (Dr. Eric Hultman), 108
Body-centred Cubic Chromium–Iron and Chromium–Manganese Alloys : Low-temperature Specific Heats of (C. T. Wei, C. H. Cheng and Prof. P. A. Beck), 315
Boelsma, E., and others : Composition of Lipids isolated from the Aorta, Coronary Arteries and Circulus Willisii of Atherosclerotic Individuals, 47
Bogoch, Elenore S. (Bogoch, Dr. Samuel, and) : Effect of Brain Ganglioside on the Heart of the Clam, 53
Bogoch, Dr. Samuel, and Bogoch, Elenore S. : Effect of Brain Ganglioside on the Heart of the Clam, 53
Bogorov, V. G., and Kreps, E. M. : Water Circulation in Oceans, 437
Bohm, D. : Problems of Collective Motion in Physics (Plasma Problems in the Electron Theory of Metals), 866
Bohr, Dr. Niels : Atomic Physics and Human Knowledge, *review* by Prof. W. H. McCrea, 1218
Bohr Effect : Molecular Adaptation in Haemoglobins—Nature of the (Austen Riggs), 1037
Bok, Prof. Bart J. : The Astronomer's Universe, *review* by Sir H. Spencer Jones, 1221
Bolognari, A. : Ultrastructure of Nucleoli in Oocytes of *Patella coerulea*, 1136
Bolton, Dr. J. G. : Appointed the first director of the newly-established Radio Observatory of the California Institute of Technology, 506 ; work of, 506
Boltz, C. L. : Appointed Science Correspondent in the News Division of the British Broadcasting Corporation, 1231 ; work of, 1231
Bombay : Shorewards Upslope of the Layer of Minimum Oxygen off—its Influences on Marine Biology, especially Fisheries (Dr. J. N. Carruthers, S. S. Gogate, J. R. Naidu and T. Laevastu), 1084
Bombardment (Electron) : Effects of, upon Bromides of Cadmium and Silver (Sho Suzuki), 1755
Bombing (Nuclear), and the Life of Man : The Devil's Repertoire or (Victor Gollancz), *review* by R. Brightman, 952
Bond Energies of some Alkali Fluorides (Dr. F. M. Page and Dr. T. M. Sugden), 1672
Bondi, Prof. H. : Elected a Fellow of the Royal Society, 860
Bonding (Intracellular Hydrogen), in Heterocyclic Systems (E. W. Gill and E. D. Morgan), 248
Bone : Iodine-131 Clearance-rates as an Indication of the Blood Supply of (Dr. P. G. Laing and Dr. Albert B. Ferguson, jun.), 1595
Bone and Radiostrontium (Arne Engström, Rolf Björnerstedt, Carl-Johan Clemedson and Arne Nelson), *review* by J. Vennart, 965
Bone (Animal) : Estimation of Strontium in, using X-Ray Fluorescence Analysis (W. M. B. Roberts), 887
Bone-Marrow in Irradiated Mice : Effect of Pyrimidine Deoxyribonucleotides on the Regeneration of (Dr. Z. Karpfel, J. Soška and V. Drášil), 1600
Bones (Animal) : Radioactivity of Soils, Plant Ashes and (Sir Ernest Marsden), 924
Bonner, Prof. David : Elected a member of the United States National Academy of Sciences, 1575
Bonner, Prof. Tom : Elected a member of the United States National Academy of Sciences, 1575
Bonsall, F. F.: Appointed to the chair of pure mathematics at King's College, Newcastle-upon-Tyne, 1365 ; work of, 1365
Book (The True), about Insects (John Clegg), *review* by B. D. Moreton, 709
Booker, D. V. : Caesium-137 in Dried Milk, 921
Books : Polish Scientific (Exhibitions at Oxford, Cambridge and Glasgow), 582
Books : Recent Scientific and Technical, Supp. v, January 31 ; Supp. vi, February 28 ; Supp. vi, March 28 ; Supp. vi, April 25 ; Supp. vi, May 30 ; dcclxx, June 27
Books required for the 'Oxford English Dictionary', 1434
Books (British), and Information Services Overseas, 1417
Booth, Dr. A. : Experimental Approaches to the Problems of Growth and Form in Plants (Factors affecting the Production of Stolons in the Potato), 585
Booth, Dr. A., and others : Use of Radioactive Tracers in Studies of the Shoot Apex, 1580
Booth, Dr. D. L., and others : Nuclear Fuel Cycles (Perturbations due to Fuel Cycles), 1647
Boothroyd, Dr. A. R. : Appointed to the University of London readership in electronics at the Imperial College of Science and Technology, 794
Borasio, Dr. L. : Phosphates and Organic Substances in Nitrogen Deficiency, 513
Bordetella pertussis : Reduced Activity of Histaminase in Rats sensitized by (Makoto Niwa, Yutaka Yamadeya, Toshitaka Matsui and Prof. Yoshio Kuwajima), 755 ; (Toshitaka Matsui, Masayoshi Kishigami and Prof. Yoshio Kuwajima), 756
Boreal Age : A Marine Transgression of, in the Southernmost Part of Norway (Gunnar Gabrielsen), 1616
Borehole to the Earth's Mantle : Drilling a (Prof. Hans Pettersson), 436
Borides and Silicides of the Platinum Metals (B. Aronsson, J. Åselius and E. Stenberg), 1318
Borlaug, Dr. N. E. : Wheat Genetics, 25
Born, Dr. G. V. R., and Esnouf, Dr. M. P. : Appearance of a Phosphorus Compound in Platelet-rich Plasma on Clotting, 478
Borohydride (Sodium) : Reaction of, with Wool (J. M. Gillespie), 322
Boron : Effect of, on the Rooting of Clematis Cuttings (Dr. C. J. Weiser), 559
  Isotopic Composition of, and its Atomic Weight (W. J. Lehmann and I. Shapiro), 1324
Boron Supply : Effect of, on the Sugars, Soluble in 80 per cent Ethanol, in Flax Seedlings (T. F. Neales), 483
Borradaile's Manual of Elementary Zoology, thirteenth edition, revised by W. B. Yapp, *review* by Dr. V. Fretter, 1290
Borwein, Dr. D. : Elected a Fellow of the Royal Society of Edinburgh, 719
Bosanquet, C. H. : Peak Dimensions in Gas Chromatography, 252
Bose, Dr. M. N., and Dev. Sukh: Occurrence of Two Characteristic Wealden Ferns in the Jabalpur Series, 130
Bose, N. K. : Appointed director of the Department of Anthropology, Government of India, 719 ; work of, 719
Bose—Einstein Statistics and Helium Films (A. D. Singh and R. K. Pathria), 668
Boss, Prof. Willis R. : Appointed Science Officer in the American Embassy in Tokyo, 15
Boström, Dr. Harry, and Vestermark, Anders : Ester Sulphate Pattern of Rabbit Bile, 1593
Botanic Gardens (Royal), Kew : Bicentenary of the (Dr. W. B. Turrill), 1488
  Vistas in Botany—a Volume in honour of the Bicentenary of the (edited by Dr. W. B. Turrill), *review* by Prof. W. H. Pearsall, 1484
Botanical Congress : Ninth International (Canadian Department of Agriculture), 1502
Botanical Studies : Present Trends in, *review* by Prof. W. H. Pearsall, 1484
Botany at Aberdeen, 1640
Botany : Vistas in—a Volume in honour of the Bicentenary of the Royal Botanic Gardens, Kew (edited by Dr. W. B. Turrill), *review* by Prof. W. H. Pearsall, 1484
Bothrops jararaca : Blood-clotting Activity of the Venom of (Dr. Olga B. Henriques, Dr. Fajga R. Mandelbaum and Dr. S. B. Henriques), 114
Bott, Dr. M. H. P. : Awarded the Wollaston Fund for 1959 of the Geological Society, 364
  Automatic Reduction of Geophysical Data (Use of a Digital Computer for determining the extent of Geological Formations from Surface Gravity Anomalies), 1167
Böttcher, Prof. C. J. F. : Relaxation Processes (Phenomenological Study of Dielectric Relaxation), 583
Böttcher, Prof. C. J. F., and others : Composition of Lipids isolated from the Aorta, Coronary Arteries and Circulus Willisii of Atherosclerotic Individuals, 47
Bottini, Dr. E. : Phosphates and Organic Substances in Nitrogen Deficiency, 513
Bottom Fauna (British Marine) : New Members of the (G. M. Spooner), 1695
Botvinik, Prof. M. M. :-Synthesis of Peptides (Synthesis of Optically Active Peptides from Racemic Amino-esters), 152
Boulind, Dr. H. F. : Science and Education, 300
Boundary Lubricant : Material Transfer in Monomolecular Layers of a (George L. Gaines, jun.), 1110
Boundary Problems in Differential Equations (Mathematics Research Center, United States Army, Symposium on, at the University of Wisconsin), 224
Bourne, Prof. Geoffrey H., and Golarz, M. Nelly: Human Muscular Dystrophy as an Aberration of the Connective Tissue, 1741
Bovey, Dr. Frank A. : The Effects of Ionizing Radiation on Natural and Synthetic High Polymers, *review* by Prof. C. E. H. Bawn, 637
Bovine Testis and Spermatic Vein Blood : Androgens in the (H. R. Lindner), 1605
Bowen, Dr. D. H. : Hydrogen Liquefaction, 1504
Bowen, H. J. M., and Smith, S. R. : Effect of γ-Radiation on Weeds, 907
Bowen, J. H., and Masters, E. F. O. : Nuclear Reactor Control and Instrumentation, *review* by R. Vaux, 1149
Bowie (William) Medal awarded to Prof. W. M. Elsasser, 1502
Bowman, J. C., and Archibald, J. D. H. : Effect on Controlled Lighting on Production Characters in the Fowl, 1138
Bownas, Geoffrey : Awarded a research grant by the Leverhulme Trust, 1499
Bowyer, E. C. : Honorary Companionship of the Royal Aeronautical Society conferred on, 1648
Boycott, B. B., and Guillery, Dr. R. W. : Environmental Temperature and the Reptilian Nervous System, 62
Boyd, Dr. R. L. F. : Gas Discharges (Probe Measurements in Striated Positive Columns), 93
  Space Research, 361
  Title of reader in physics in the University of London (at University College) conferred on, 368
Boyle, Robert, and Seventeenth-Century Chemistry (Prof. Marie Boas), *review* by Dr. R. E. W. Maddison, 850
Brabazon of Tara, Lord : Elected president of the Royal Institution, 1571
Brachiosaurus Exhibition at the Smithsonian Institution, 649
Brackman, W. : Co-ordination Chemistry (Copper–Amine Complexes which Catalyse the Oxidation of Alcohols), 1785
Bradbury, A., and others : Removal of Dipolar Broadening of Nuclear Magnetic Resonance Spectra of Solids by Specimen Rotation, 1802
Bradbury, E. M., and others : α-Helices and a New Polypeptide Fold in Poly-β-Benzyl-L-Aspartate, 1736
Bradbury, Dr. F. R., and Standen, H. : Metabolism of Benzene Hexachloride by Resistant Houseflies, *Musca domestica*, 983

- Bradbury, Dr. J. H. : Separation and Analysis of Scale-rich Material from Wool, 305
- Bradbury, S. : Methods of Analytical Histology and Histo-Chemistry, *review*, 211
- Bradford Chemical Society, and others : Symposium on Radiation Chemistry, 18
- Bradford Institute of Technology : Course in Stereospecific Polymers and Block and Graft Co-polymers, 224
- Bradford Institute of Technology (Department of Chemical Technology), and others : Symposium on Radiation Chemistry, 18
- Bradley, D. E. : Electron-Microscopic Study of Finback Whale Myoglobin Crystals, 941
- Bradley, Dr. P. B. : The Excitable Cortex in Conscious Man, *review*, 781
  - Neurophysiology of Behaviour, *review*, 954
- Bradley, Dr. W. F. : Density of Water Sorbed on Montmorillonite, 1614
- Bradshaw, A. D., and Snaydon, R. W. : Population Differentiation within Plant Species in Response to Soil Factors, 129, *erratum*, 368
- Braekkan, Olaf R. : Red Muscle as a Possible Character for the Identification of Sharks, 556
- Braham, Roscoe R. (Byers, Horace R., and) : Grant of 114,300 dollars from the National Science Foundation, for a study of the physical effects of silver iodide seeding over the Great Plains, 1371
- Brahmachari, Dr. H. D., and Kumar, Mahendra : Effect of β-Hydroxybutyrate Injections on the Pancreatic Activity of Guinea Pigs, 51
- Braille Translation by Computer, 1233
- Brain, C. K. : The Transvaal Ape-Man-bearing Cave Deposits, 1433
- Brain, Sir Russell : Science, Philosophy and Religion (Eddington Memorial Lecture for 1959), 154, 1022
- Brain : Thudichum—Chemist of the (Prof. David L. Drabkin), *review* by H. W. Kosterlitz, 568
  - The Computer and the (Dr. John von Neumann), *review* by A. H. Armstrong, 350
- Brain (Rat) : Effect of Toxopyrimidine on Glutamic-decarboxylase and Glutamic-oxalacetic Transaminase of (Dr. G. Rindi, V. Perri and U. Ventura), 1126
- Brain of the Living Rat : Formation of Urea from Arginine in the (Michael B. Sporn, Wesley Dingman, Alfred Defalco and Robert K. Davies), 1520
- Brain-case of the Common Shrew (*Sorex araneus* L.) : Seasonal Changes in the (Peter Crowcroft and Jean M. Ingles), 907
- Brain Damage : Oxygen Exposure and (Lars Gyllenstein), 1068
- Brain Extracts : Fractionation of, for Acid Phosphatase-elevating Activity (Dr. V. Schreiber, Prof. J. Charvát, V. Kmentová and M. Rybák), 473
- Brain Ganglioside : Effect of, on the Heart of the Clam (Dr. Samuel Bogoch and Elenore S. Bogoch), 53
- Brain Stem (Rat): Selective Staining of Visceral Efferents in the, by a Modified Koelle Technique (Dr. P. R. Lewis and Dr. C. C. D. Shute), 1743
- Brain Tissue of Rats : Succinic Dehydrogenase Activity in, after Ovariectomy and Steroid Administration (H. Sobel and B. Eckstein), 54
- Brains of Rats treated with Toxopyrimidine : γ-Aminobutyric Acid and Glutamic Acid Content of (Dr. G. Rindi and G. Ferrari), 608
- Braithwaite, E. R. : Measurement of the Flocculation of Suspensions, 740
- Bramhall, James L. (Ruebner, Dr. Boris, and) : Effect of Dietary Protein on the Severity of Experimental Mouse Hepatitis, 609
- Branch Prize of the Royal Aeronautical Society awarded to B. D. Blackwell, 1649
- Branded Textiles Group (Textile Institute, in collaboration with the) : Conference on Detergents, Textiles and Dyes, 1236
- Brandhorst, Dr. Wilhelm : Relationship between the Hake Fishery and a Southerly Sub-surface Return Flow below the Peru Current off the Chilean Coast, 1832
- Brandly, C. A., and Jungherr, E. L. (edited by) : Advances in Veterinary Science, Vol. 4, *review* by Prof. H. Burrow, 1555
- *Brassica oleracea* var. (Chou Moellier) : A Germination Inhibitor and Root-Growth Retarder in (A. G. Campbell), 1263
- Brassington, Nancy (Haber, Alan H., and) : Non-respiratory Gas released from Seeds during Moistening, 619
- Brattain; Dr. Walter : Elected a member of the United States National Academy of Sciences, 1575
- Brattström, Prof. Hans : Pogonophora in the Hardnagerfjord, Western Norway, 1458
- Braun, Dr. P., and others : Determination of Transaminase Activity in Dogs' Serum and Lymph after Hepatic Damage due to Acute Biliary Obstruction, 48
  - Changes in Serum Transaminase Activity following Myocardial Damage due to Lymphatic Congestion, 1333
- Braun-Falco, Dr. O., and Salfeld, Dr. K. : Leucine Aminopeptidase Activity in Mast Cells, 51
- Bray, R. J. (Loughhead, R. E., and) : 'Turbulence' and the Photospheric Granulation, 240
- Bray, W. J. : Awarded a Premium by the Radio Industry Council, 1023
- Braye, E. H. (Hübel, W., and) : Co-ordination Chemistry (New Compounds from Iron Dodecacarbonyl and Acetylenes), 1785
- Bread (Whole), and Bread Crumb : Moisture Content of (Y. Pomeranz), 1122
- Bread Crumb : Moisture Content of Whole Bread and (Y. Pomeranz), 1122
- Breakdown : Light Emission from Insulating Liquids due to Excitation by d.c. Fields near (M. Darveniza), 743
- Breakdown of Homogeneous Field and Sphere Gaps : Effect of Radiation on the (K. R. Allen and Dr. K. Phillips), 233
- Breakdown of a 1-cm. Homogeneous Field Spark Gap in Air : Effect of Humidity on the (Dr. K. Phillips, K. R. Allen and A. Refsum), 532
- Breakdown Voltage (Spark) : Effect of Humidity on the (K. R. Allen and Dr. K. Phillips), 174
- Breast Cancer (Human) : Variables related to (A. Elving Anderson, Harold O. Goodman and Sheldon C. Reed), *review* by Dr. L. Foulds, 955
- Breast Muscles (Poultry), at Slaughter : Changes in *p*H and Temperature in (F. E. Peters and J. W. Dodge), 687
- Breast Tumours in Mice of the *IF* Strain : Local Inhibition by Lactation of chemically induced (June Marchant), 629
- Breccia, A., and others : Labelled Keto-Acids in Duck Blood incubated *in vitro* with $NaH^{14}CO_3$, 1328
- Breeding of *Anopheles gambiae* : Relationship between Salinity and, in North-Eastern Tanganyika (A. Smith and J. W. Vail), 1203
- Breeding of Small Animals : Measuring Productivity in (Dr. W. Lane-Petter, Annie M. Brown, Margaret J. Cook, G. Porter and A. A. Tuffery), 339
- Breeding 10,000,000 Cattle (Milk Marketing Board), 1641
- Bremner, Dr. J. M., and others : Release of Fixed Ammonium from Soil by Ball Milling, 1414
- Brennan, Dr. D., and Fletcher, P. C. : Heterogeneous Atomization of Hydrogen and Oxygen, 249
- Brenner, Prof. M. : Synthesis of Peptides (Peptides of the Hydroxy-amino-Acids), 152
- Brewbaker, Dr. J. L., and Shapiro, N. : Homozygosity and *S* Gene Mutation, 1209
- Brewer, Prof. Leo : Elected a member of the United States National Academy of Sciences, 1575
- Brewer, Ralph : Awarded the United States National Reliability Award for 1958, 365 ; work of, 365
- Brewer's Yeast : Endogenous Metabolism of Freshly Harvested Cells of a (V. E. Chester), 902
- Brian, Dr. P. W. : Experimental Approaches to the Problems of Growth and Form in Plants (Morphogenetic Situations in which the Gibberellic Acids were involved), 585
- Brian, Dr. P. W., and others : Effect of Gibberellic Acid on Development of Autumn Colour and Leaf-fall of Deciduous Woody Plants, 58
- Brice, J. C. (Wright, H. C., and) : Indium Mono-Telluride, 27
- Bricteux-Grégoire, Dr. S., and others : Utilization of the Carboxyl Group of Glycine for the Synthesis of the Amino-Acids of Silk by *Bombyx-mori*, *erratum*, 294
- Bridgers, H. E., and others (edited by) : Transistor Technology, Vol. I, *review* by Dr. J. R. Tillman, 72
- Briggs, Prof. Asa : Appointed a member of the University Grants Committee, 86
- Briggs, Dr. C. A. E. : Microbes and Milk, *review*, 637
- Briggs, Dr. F. N. : Wheat Genetics, 25
- Briggs, J. H., and others : A Presumptive Human *XXY/XX* Mosaic, 1030
- Brightman, R. : Perkin Centenary—London, *review*, 709
  - Information Service in Libraries, *review*, 781
  - 'Arms and the Man', *review*, 952
  - Science and Society, *review*, 1702
- Brighton Technical College : Residential Working Conference on Automatic Programming of Digital Computers, 438, 1779
- Brill, Prof. R., and Zandy, H. : Absolute Measurement of the Intensity of the (111) Reflexion for Diamond, 1387
- Brillouin, Prof. L. : Information Theory and its Applications to Fundamental Problems in Physics, 501
- Brimble, L. J. F. : The Rockefeller Institute, New York—a New Graduate University, 1629
- Brindley, Prof. G. W., and Nakahira, Dr. M. : Evidence for a Variable Long-range Order in nearly Anhydrous Gamma Alumina, 1620
- Briner, G. P. (Johnstone, B.M., and) : Quantitative Estimation of Purines by the Visual Scanning of Photographs of Paper Chromatograms, 681
- Brines (Fish and Meat Curing) : The Microbiology of—Proceedings of the Second International Symposium on Food Microbiology (Cambridge, 1957), (edited by Dr. B. P. Eddy), *review* by Dr. Magnus Pyke, 351
- Brink, Prof. Frank : Elected a member of the United States National Academy of Sciences, 1575
- Brinkhous, Prof. Kenneth M. (edited by) : Hemophilia and Hemophilioid Diseases—International Symposium, *review* by Prof. J. V. Dacie, 1221
- Brinton, jun., Dr. Charles C. : Non-Flagellar Appendages of Bacteria, 782
- Bristowe, Dr. W. S. : The World of Spiders, *review* by Dr. Eric Duffey, 1079
- Britain : Bulk Production of Silicon in (Imperial Chemical Industries, Ltd.), 932
  - Finance of Scientific Research in, 156
  - Fuel and Power in (House of Lords Debate on), 511
  - Funds for Commonwealth Students in, 793
  - Future of Television in, 222
  - Government Aid to Science in (House of Commons Debate on), 156
  - Grants to Students in (National Union of Students Memorandum on), 864
  - Increased Grants for Universities in, 507
  - Industrial Health in, 867
  - Inland Waterways in (House of Lords Debate on), 1305
  - Library Services in, 1287
  - Manufacture of Polypropylene in, 1162
  - New Nature Reserves in, 1649
  - Power Stations in, 794
  - Preservation of the Countryside in, 917
  - Production and Marketing of Radioactive Isotopes in, 720
  - Reorganization of Industrial Microbiological Research in, 1
  - Reorganization of Microbiological Research in (D. J. B. Copp), 416
  - Research on Fuel and Power in, 507
  - Scientific Man-power and Development in, 67
  - Scientific and Technological Research in, 847
  - Secondary Education in, 511
  - Space Research in, 1231, 1302, 1568
  - Trees of (Dr. Robert Gurney), *review* by Dr. F. N. Howes, 1627
  - See *also under* Great Britain
- British Agricultural History Society and the Economic History Society : Joint Conference on Agriculture and Rural Life, 582
- British Army in the Second World War : Psychiatry in the (Dr. Robert H. Ahrenfeldt), *review* by Dr. D. Russell Davis, 208
- British Association for the Advancement of Science : Science in Schools—Proceedings of a Conference under the auspices of the (London, 1958), (edited by W. H. Perkins), *review*, 211
  - Granada Lectures (Communication in the Modern World), 293
  - Formation by Section H of a special Committee to investigate the Denudation and Burial of Archaeological Structures, 1233
  - Directory of Natural History and other Field Studies, 1723
- British Association Looks Ahead (Prof. P. M. S. Blackett), 1569
- British Association of Allergists (British Society for Immunology and the) : Symposium on the Immunological Aspects of Allergic Disorders, 296
- British Association of Corrosion Engineers : Formation of, 1779
- British Books and Information Services Overseas, 1417
- British Broadcasting Corporation : Appointment of C. L. Boltz as Science Correspondent in the News Division, 1231
  - Annual Grant of £5,000 for three years to the Council for Nature, for the establishment of an Intelligence Unit, 1231
  - Reith Lectures (Prof. A. C. B. Lovell), *review* by Dr. R. A. Lyttleton, 1624

British Cast Iron Research Association : Retirement of Dr. J. G. Pearce from the directorship, 84
Appointment of H. Morrogh as director, 84
Open Days, 1434
British Cattle : The Nematodes *Ostertagia lyrata* Sjöberg, 1926, and *Trichostrongylus longispicularis* Gordon, 1933, in (Dr. J. H. Rose), 1745
British Coal Utilization Research Association : Open Days, 1024, 1786
British Commonwealth : Scientific Co-operation within the (H.R.H. the Duke of Edinburgh,) 425
British Commonwealth, Association of Universities of the : Report of the Executive Council for 1957-58, 1717
Report of the Proceedings of the 1958 Home Universities Conference, 1764
British Compounding Ingredients for Rubber (compiled by Brian J. Wilson), *review* by Dr. W. J. S. Naunton, 779
British Computer Society, and others : Joint Symposium on Instrumentation and Computation in Process Development and Plant Design, 652
British Congress of Cosmetic Science (Society of Cosmetic Chemists), 934
British Council : Scholarships Abroad (1959-60), 650
Annual Report for 1957-58, 659
British Council (Soviet Relations Committee), and the Soviet State Committee for Cultural Relations with Foreign Countries : Discussions on Anglo-Soviet educational and other exchanges, 582
British East African Waters : Marlins in (F. Williams), 762
British Embassies Overseas : Scientific Attachés on the staffs of, 16
British Embassy in Moscow : Appointment of D. A. Senior as scientific attaché, 1018
British Empire Cancer Campaign : Grant of £8,341 to the University of Bristol, for cancer research to be carried out in the Departments of Pathology, Physiology and Surgery, 581
British Fauna : A Monogenetic Trematode New to the (Z. Kabata), 481
British Fermentation Industries (J. M. Whitmarsh), *review*, 967
British Flora during 1958 (J. E. Lousley), 869
British Forestry : Progress in (Sir Harry Champion), 1100
British Gelatine and Glue Research Association : Sixteenth meeting of the Research Panel, 440
British Glaciological Society (Royal Astronomical Society and the) : Geophysical Discussion on Characteristics of the Antarctic Ice-Sheet, 1575
British Gold Medal for Aeronautics of the Royal Aeronautical Society awarded to R. S. Stafford, 1648
British Industry : Fuel and Power in (A. M. Wandless), 154
Graduates in (Department of Scientific and Industrial Research), 864
British Institute of Management : Conference on Changing Industry, 655
British Institution of Radio Engineers : Election of Erik K. Cole as an honorary member, 582
Convention on Television Engineering in Science, Industry and Broadcasting, 1234
British Iron and Steel Research Association (Iron and Steel Institute and the) : Translation Service of the, 224
British Journal of Psychology : Monograph Supplement 31, Figural After-Effects (Dr. Peter McEwen), 1027
British Manufacturing Industry, 1955 : Estimates of Resources devoted to Scientific and Engineering Research and Development in (Department of Scientific and Industrial Research), 847
British Marine Bottom Fauna : New Members of the (G. M. Spooner), 1695
British Marine Fishes, *review* by Dr. D. P. Wilson, 140
British Medical Bulletin, Vol. 15, No. 1, Recent Advances in Haematology, 1372
British Mineral Deposits : Isotopic Composition of Lead from (S. Moorbath), 595
British Museum : Retirement of Dr. H. J. Plenderleith from the keepership of the Research Laboratory, 791
Appointment of Dr. A. E. A. Werner as keeper of the Research Laboratory, 792
British Museum (Natural History) : Appointment of W. A. Ferguson as secretary, 18, 154
Nuffield Collection of Meteorites at the, 221
Appointment of Dr. A. A. Moss as deputy keeper of the Department of Mineralogy, 1304
British National Committee on Antarctic Research : To co-ordinate British Antarctic Activities, 292
Appointment of Sir Raymond Priestley as chairman, 292
British Nuclear Energy Conference (Institute of Physics, in collaboration with the) : Symposium on Nuclear Fuel Cycles, 1646
British Occupational Hygiene Society : Conference on the Control of Dust and Fumes in Industry, 865
British Plastics Federation : Conference on Reinforced Plastics, 24
British Polarographic Research Society : Course in Polarography, 18
British Rubber Manufacturers, Research Association of : British Compounding Ingredients for Rubber (compiled by Brian J. Wilson), *review* by Dr. W. J. S. Naunton, 779
British Scientific Attaché in Moscow, 1018
British Scientific Attachés Overseas, 16
British Scientific Film Association : Thirteenth Congress of the International Scientific Film Association, 1783
British Scientific Instrument Research Association : Establishment of an Electrical Instrument Test Service, 436
British Silver Medal for Aeronautics of the Royal Aeronautical Society awarded to D. J. Farrar, 1648
British Society for Immunology and the British Association of Allergists : Symposium on Immunological Aspects of Allergic Disorders, 296
British Society for the Philosophy of Science : Fourth Annual Conference, 1783
British Sociological Association (Scottish Branch) : Conference to mark the Centenary of 'The Origin of Species', 1562
British Spiders : Natural History of, *review* by Dr. Eric Duffey, 1079
British Standards Institution : B.S.3044, Anatomical, Physiological and Anthropometric Principles in the Design of Office Chairs and Tables (Dr. W. F. Floyd and Dr. D. F. Roberts), 1022
British Steel Industry, 222
British Trust for Ornithology : *Bird Migration*, Vol. 1, No. 1, 436
British Water Beetles (Prof. Frank Balfour-Browne), Vol. 3, *review* by Dorothy J. Jackson, 1420
Brittain, F. H. : Stereophonic Sound Recording, Reproduction and Broadcasting (Directional Hearing), 1720
Brittain, R. T., and others : Resolution of Chlorpheniramine and the Pharmacological Properties of its Isomers, 734
Broad Bean Seeds : Effect of Light on Maturing (Dr. G. R. Lane and R. D. Butler), 1063
Broadbent, Prof. T. A. A. : Legendre Functions, *review*, 1421
Modern Tauberian Analysis, *review*, 1626
Mathematics for the Physical Sciences, *review*, 1703
Applied Analysis in the U.S.S.R., *review*, 1766
Broadcasting : Stereophonic Sound Recording, Reproduction and (Institution of Electrical Engineers Convention on), 1720
Television Engineering in Science, Industry and (British Institution of Radio Engineers Convention on), 1234
Broadening of the X-Ray Diffraction Lines in Teeth affected by Fluorine (E. A. Scott and Dr. F. H. Scott), 479
Broadening (Dipolar), of Nuclear Magnetic Resonance Spectra of Solids : Removal of, by Specimen Rotation (Prof. E. R. Andrew, A. Bradbury and R. G. Eades), 1802
Broda, Prof. Engelbert : Radioaktive Isotope in der Biochemie, *review* by Dr. H. R. V. Arnstein, 1149
Brodie, Bernard B., and others : Cotinine, an Oxidation Product of Nicotine formed by Rabbit Liver, 47
Broecker, W. S., and others : Radiocarbon Measurements on Samples of Known Age, 1582
Bromides of Cadmium and Silver : Effects of Electron Bombardment upon (Sho Suzuki), 1755
Bromination of Dimethylaniline : Kinetic Isotope Effect in the (P. G. Farrell and Dr. S. F. Mason), 250
Bromination of Nucleic Acids and their Derivatives (A. S. Jones and D. L. Woodhouse), 1603
1,6-Di-(2-Bromoethylamino)-1,6-Dideoxy-D-Mannitol Dihydrobromide, a New Cytostatic Agent (L. Vargha and T. Horváth), 394
1,6-Di-(2-Bromoethylamino)-1,6-Dideoxy-D-Mannitol Dihydrobromide : Effect of, on Tumours of Laboratory Animals (Prof. J. Baló, G. Kendrey, J. Juhász and I. Besznyák), 395
Bronchial Cancer : Chemical Changes in Human Bronchial Epithelium and their relation to (J. Chayen, Prof. G. J. Cunningham and D. P. Winstanley), 1743
Bronchial Epithelium (Human) : Chemical Changes in, and their relation to Bronchial Cancer (J. Chayen, Prof. G. J. Cunningham and D. P. Winstanley), 1743
Bronchial Mucus Gel : Mucoprotein of (J. C. White, P. C. Elmes and W. Whitley), 1810
Bronk, Dr. Detlev W. (Waterman, Dr. Alan T., and) : The Argus High-Altitude Geophysical Experiments, 1019
Bronowski, Dr. J. : Darwinism and the Study of Society, 1563
Bronze Age : Life and Death in the (Sir Cyril Fox), *review* by M. C. Burkitt, 1486
Bronze Medal of the Royal Aeronautical Society awarded to D. G. King-Hele, 1648
Brook Trout : X-Ray Diffraction Patterns from the Egg Membrane of the Egg of the (Dr. Mamoru Kusa and Tsuguyasu Wada), 410
Brookhaven Medical Research Center : The Medical Research Reactor at the (Dr. E. E. Stickley), 1013
Brookhaven Symposium in Biology : Twelfth (Structure and Function of Genetic Elements), 1094
Brooks, J. D. : The Nature of Coal (Principal Chemical Methods of Investigating the Constitution of Coals), 1438
Brooks, Dr. John Langdon : The Systematics of North American *Daphnia*, 93
Brot, Dr. C. : Relaxation Processes (Dielectric Studies on Liquid Monoalcohols of Medium Chain-length), 584
Brown, A., and Norreys, J. J. : Beta-Polymorphs of Uranium and Thorium Disilicides, 673
Brown, Dr. A. E. : Of What Use is Acoustics to the Musician ?, 1294
Brown, Dr. A. F. : Elected a Fellow of the Royal Society of Edinburgh, 719
Brown, Annie M., and others : Measuring Productivity in Breeding of Small Animals, 339
Brown, Dr. A. W. A. : Insecticide Resistance in Arthropods, 1508
Brown, Dr. B. R. : Chemistry of Condensed Tannins (Acid-catalysed Polymerization of Phenolic Compounds), 1168
Brown, D. A. : Co-ordination Chemistry (Effect of Phenyl-substitution on the Stability of Sandwich Compounds), 1785
Brown, Dr. Donald D., and others : Enzymatic N-Methylation of Histamine, 680
Brown, Dr. E. H. : Appointed reader in structural analysis at the Imperial College of Science and Technology, 1571
Brown, F., and Graves, J. H. : Changes in Specificity and Electrophoretic Mobility of the Precipitating Antibodies present in the Serum of Cattle recovering from Foot-and-Mouth Disease, 1688
Brown, G. I. : An Introduction to Electronic Theories of Organic Chemistry, *review* by Dr. R. I. Reed, 279
Brown, I. D., and Dunitz, J. D. : Co-ordination Chemistry (The Cuprous-Diazoamino-benzene Complex), 1784
Brown, Dr. Juliet C. (Sewell, Dr. Geoffrey W. F., and) : Ecology of *Mucor ramannianus* Moller, 1344
Brown, Sir Lindor : Opening Address to the International Conference on Scientific Information (Desirability of Discipline and Restraint on the part of Authors of Scientific Papers), 147
Brown, L., and others : α-Helices and a New Polypeptide Fold in Poly-β-Benzyl-L-Aspartate, 1736
Brown, Paul K., and others : Action of Light on Visual Pigments—Vertebrate Lumi- and Meta-Rhodopsins, 442 ; Lumi- and Meta-Rhodopsins of Squid and Octopus, 446
Brown, Prof. R. : Elected a Fellow of the Royal Society of Edinburgh, 719
Brown, Dr. T. W. F. : *Obituary* of Sir Claude Gibb, 504
Brown Streak Virus (Cassava) : Mechanical Transmission of (R. M. Lister), 1588
Browning, B. H., and others : Inactivation of Organo-Mercurial Fungicides in Groundwood Pulp made from Logs stored in Salt Water, and the Possible Role of Sulphur Compounds, 1346
Bruce, Prof. F. M., and others : Gas Discharges (Spark, High-frequency and Glow Discharges), 93
Bruce (Dr. W. S.) Memorial Prize for 1958 awarded to Dr. Hal Lister, 1719
Brucella : Immunizing Properties of Insoluble Cell Material derived from (J. Markenson, D. Sulitzeanu and Prof. A. L. Olitzki), 1693
Brucker, W. M. : Replica of *Explorer I*, together with its *Jupiter-C* Carrier Rocket, presented to the Smithsonian Institution by, 510

Brumbaugh (Martin, G.) Lectures in Education—The Emergence of the Modern Mind (edited by Prof. Frederick C. Gruber), *review* by T. H. B. Hollins, 953
Brunel, Isambard Kingdom : Exhibition to commemorate the centenary of the death of (Engineering Laboratory, Cambridge), 1164
Brunner, Prof. William : *Obituary* by Prof. M. Waldmeier, 290
Bruno, M., and Croatto, Prof. U. : Structural Chemistry of Promethium, 601
Brunt, A. A.: Leaf-Enations in *Dahlia variabilis* Desf. induced by Tomato Spotted Wilt Virus, 627
Bubar, J. S. : Differences between Self-Incompatibility and Self-Sterility, 411
Buckell, Dr. Monamy, and Truscott, Margaret : Salt Concentration and Fibrinolytic Activity, 1268
Buckingham, Sue, and others : Bilirubin Metabolism in the Foetus, 1823
Buckland, F. E. : Impairment of Viral Haemagglutination of Red Cells after Treatment with Formalin, 1276
Bud Reactivation in *Splachnum ampullaceum* (L.) Hedw. : Interaction between Kinetin and Indoleacetic Acid in the Control of (Prof. K. E. von Maltzahn), 60
Buddington, A. F., and others : Magneto-striction and Palaeomagnetism of Igneous Rocks, 1318
Buds (Shoot), on the Protonema of *Pohlia mutans* : Effects of Kinetin, Gibberellic Acid and certain Auxins on the Development of (Dr. G. C. Mitra and Dr. A. Allsopp), 974
Bug (Mealy), *Planococcus citri* (Risso) : Triple Coitus in the (Walter A. Nelson-Rees), 479
Bugher, Dr. John C. : Appointed consultant on nuclear energy, Rockefeller Foundation, 1018
Building Research (Department of Scientific and Industrial Research to be the only Government Department with responsibility for), 94, 1367
Building Research, Studies and Documentation, International Council for : International Congress in Rotterdam, 1783
Bukovac, Prof. Martin J., and Davidson, Harold : Gibberellin Effects on Photoperiod-controlled Growth of *Weigela*, 59
Bulbil Formation in *Sedum telephium* (Dr. E. C. Humphries and J. M. Thurston), 1343
Bulbrook, R. D., and others : Changes in Œstrogen Titre in Stored Urine, 189
Bulge : The—its Industrial Impact (John Wellens), 1500
Bullard, Sir Edward : Automatic Reduction of Geophysical Data, 1167
Buller, Dr. A. J., and others : Fast and Slow Muscles in Mammals, 1516
Bulloch, R. S., and others : Nuclear Fuel Cycles (Perturbations due to Fuel Cycles), 1647
Bullough, Dr. R. : Interfacial Phenomena (Low-Energy Interfaces associated with Deformation Twins), 1098
Bullough, Dr. R., and others : Precipitation on a Dislocation, 34
Bulls : A Rare Sperm Abnormality—'Corkscrew-sperms' associated with Sterility in (Dr. Erik Blom), 1280
Bunn, Dr. C. W. : Relaxation Processes, 583
Bunt, Dr. J. S. : Marine Studies in the Inshore Waters of Antarctica near Mawson (1956), 1541
Bunton, Dr. C. A., and others: Oxidation of Ascorbic Acid and similar Reductones by Nitrous Acid, 163
Bur, Grato E., and others : Distribution of Alkaline Phosphatase in the Arteries of several Species, 1262
Burch, Dr. P. R. J. : Measurements at Leeds following the Windscale Reactor Accident—Iodine-131 in Human Thyroids and Iodine-131 and Caesium-137 in Milk, 515
Burchardt, Dr. F. A. : *Obituary* by K. G. J. C. Knowles, 577
Burden Neurological Institute, Bristol : Retirement of Prof. F. L. Golla from the directorship, 220
  Appointment of Dr. W. Ross Ashby as director, 220, 510
Burdin, M. L., and Prydie, J. : Lumpy Skin Disease of Cattle in Kenya, 949
Burges, Prof. Alan : Micro-organisms in the Soil, *review* by D. M. Webley, 1010
Burgess, B., and others : Deduction of Ionospheric Electron Content from the Fading of Signals from Artificial Earth Stellites, 1172
Burial of Archaeological Structures : Denudation and (Formation by Section H of the British Association for the Advancement of Science of a special Committee to investigate the), 1233
Burkard, Prof. O. : Radio Reflexions from the Moon and Solar Corona, 1180
Burkholder, Lillian M., and others : Chlorophyll *a* in some Corals and Marine Plants, 1338
Burkholder, Dr. Paul R., and others : Chlorophyll *a* in some Corals and Marine Plants, 1338
Burkitt, M. C. : Avian Folklore, *review*, 1422
  Reconstructing the Past, *review*, 1486
Burks, Arthur W. (edited by) : Collected Papers of Charles Sanders Pierce, Vol. 7, Science and Philosophy ; Vol. 8, Reviews, Correspondence and Bibliography, *review* by F. I. G. Rawlins, 276
Burn, Prof. J. H. : Retirement from the chair of pharmacology in the University of Oxford, 790 ; work of, 790
Burns, Dr. B. Delisle: Self-regulation in Living Systems (Knowledge of the Nervous System), 370
Burns, Tom : Darwinism and the Study of Society, 1562
Burnstock, Dr. G. : Elected to a Junior Fellowship by the Beit Memorial Trust, 1569
Burrow, Prof. H. : Advances in Veterinary Science, *review*, 1555
Burrows, Dr. E. M. : Experimental Approaches to the Problems of Growth and Form in Plants (Growth and Form of Algae), 585
Bursaries Scheme (Commonwealth) : Fifth Annual Report on the (Royal Society and Nuffield Foundation), 1304
Bursts (Metre-Wave and 3-cm. Wave) : Time Relationship of (M. R. Kundu), 1047
Burt, A. D., and Andrews, D. R. : Stereophonic Sound Recording, Reproduction and Broadcasting (Magnetic Tape Recording), 1720
Burton, Dr. A. : Self-regulation in Living Systems (Handling of Visual Information), 370
Busch, Suzanne, and others : Are Nucleoside Triphosphates Precursors of Mammalian Ribonucleic Acid *in vivo?*, 1114
Bush, Prof. Douglas : Education in the Age of Science, 1436
Bushmen (Central Kalahari) : Blood-Group Investigation on (Dr. J. S. Weiner and Dr. A. Zoutendyk), 843
Bushmen (Kalahari) : The Nuffield—Witwatersrand University Expeditions to, 1958-59 (Prof. P. V. Tobias), 1011
Business : Electronic Computers in the Service of (W. L. C. Garrett), 11
Business Computer Symposium : Electronic Computer Exhibition and, 11
Business Machines Corporation (International), Cortlandt, New York : Appointment of Dr. Herman H. Goldstine as resident manager of the Lamb Estate Research Center, 1502
  Appointment of Dr. H. J. Greenberg as manager of the Mathematics Theory Department of the Lamb Estate Research Center, 1502
Busk (Edward) Memorial Prize of the Royal Aeronautical Society awarded to T. R. F. Nonweiler, 1648
Butler, Dr. H. E. : Elected a Fellow of the Royal Society of Edinburgh, 719
Butler, R. D. (Lane, Dr. G. R., and) : Experimental Approaches to the Problems of Growth and Form in Plants (Apical Development in relation to Etiolation), 585
  Effect of Light on Maturing Broad Bean Seeds, 1063
Butler, Warren L., and Siegelman, H. W. : Conversion of Caffeic Acid to Esculetin during Paper Chromatography, 1813
Buttery, S. : Detection of Antigens as Specific Precipitates on Paper Electrophoresis Strips, 686
γ-Butyrobetaine : Pharmacological Actions of (Dr. E. A. Hosein and Prof. H. McLennan), 328
Butzko, Robert L. : Plastic Sheet Forming, *review* by Dr. S. H. Pinner, 851
Byers, Horace R. : Grant of 383,700 dollars from the National Science Foundation, for research in cloud physics, covering the factors believed to be important in precipitation mechanisms, 1371
Byers, Horace R., and Braham, Roscoe, R. : Grant of 114,300 dollars from the National Science Foundation, for a study of the physical effects of silver iodide seeding over the Great Plains, 1371

CABLE, M. : Appointed lecturer in glass technology at the University of Sheffield, 1024
Cables (Electric) : Development of (S. E. Goodall), 226 ; (Prof. James Greig), 226
Cacao (Witch Broom Disease of) : Absence of Gibberellin-like Substances in Filtrates of *Marasmius perniciosus* Stahel (W. F. Dudman and R. Nichols), 899
Cade, C. M. : Awarded the Navigation Prize of the Royal Aeronautical Society, 1649
Cadmium Sulphide (Polycrystalline), and Polyethylene : Conductivity induced by Radiation in (C. G. Clayton, B. C. Haywood and Dr. F. J. Fowler), 1112
Cadmium and Silver : Effects of Electron Bombardment upon Bromides of (Sho Suzuki), 1755
Caeca (Genal), of Agnostids (A. A. Öpik), 1750
Caeruloplasmin from the *G*2 Fraction of Human Plasma : Preparation of (Dr. G. Curzon and L. Vallet), 751
Caesium-137 in Milk : Iodine-131 in Human Thyroids and Iodine-131 and (Measurements at Leeds following the Windscale Reactor Accident), (Dr. P. R. J. Burch), 515
Caesium-137 in Dried Milk (D. V. Booker), 921
Caesium-137 in Swedish Milk and Soil (K. Löw and K. Edvarson), 1104
Caesium-Beam Standard of Frequency : Canadian (S. N. Kalra, R. Bailey and H. Daams), 575
Caffeic Acid to Esculetin : Conversion of, during Paper Chromatography (Warren L. Butler and H. W. Siegelman), 1813
Cagliotti, V., and co-workers : Co-ordination Chemistry (Preparation and Reduction of the Oxygen Adducts of Cobalt (II)–Histidine Complexes), 1785
Calcification (Aortic Medial), and Lowered Metabolism in Ground Squirrels (Dr. George R. Zimmerman and Prof. G. Edgar Folk, jun.), 754
Calcite Cleavage Faces : Etch Pits on (Dr. H. Watts), 314 ; (R. C. Stanley), 1548
Calcium : Micro Determination of (A. B. Gilbert), 888, 1754
  Separation of Strontium-90 from (P. S. Davis), 674
Calcium in Milk : Separation of Strontium-90 from (Dr. N. A. Myers), 1807
Calcium (Serum) : A Rapid Micro-quantitative Method for estimating (T. A. Harper), 232
Calcium Thymidylate : Crystal Structure of (P. Horn, Dr. V. Luzzati and Dr. K. N. Trueblood), 880
Calcium and Chloride Ion Contents and Protein Fractions in the Fluids of Chick Embryos : Sodium, Potassium, (Dr. Aleksandra Smoczkiewiczowa), 1260
Calculation of Erosion in Space from the Cosmic-Ray Exposure Ages of Meteorites (Dr. F. L. Whipple and Dr. E. L. Fireman), 1315
Calcutt, G. (Harper, K. H., and) : Glucuronide and Sulphate Conjugation *in vivo* and *in vitro*, 463
Caldecott, Dr. R. S. : Wheat Genetics, 27
Caldera (Kuttyaro) : Gravity Survey on the, by means of a Worden Gravimeter (Prof. Izumi Yokoyama and Hirokazu Tajima), 739
Caldin, Dr. E. F. : Observation and Interpretation, *review*, 1010
Caldwell, Prof. John : Persistence of Tomato Aucuba Mosaic Virus in Dried Leaf Tissue, 1142
Calendar : History of the (Y. G. Perel), 509
Calf : Lens Cells of the, in Continuous Culture (Dr. J. van der Veen and C. F. A. Heyen), 1137
Calf Serum (Precolostral) : Immunological Activity of (J. L. Turk), 838
Calicotyle : Relationship between *Dictyocotyle* and (Dr. J. Llewellyn), 835 ; (Dr. Ben Dawes and Dr. Ivor Griffiths), 835
California Institute of Technology : Grant of 73,594 dollars from the U.S. National Foundation to Dr. Renato Dulbecco, for investigations on virus inheritance in experiments involving polio virus mutations, 224
  Grant of 33,943 dollars from the U.S. National Foundation to Prof. Linus Pauling, for investigations on the structure of nucleic acids, 224
  Appointment of Dr. J. G. Bolton as first director of the newly established Radio Observatory, 506
Calkins, Dr. Evan (Cohen, Dr. Alan S., and) : Electron Microscopic Observations on a Fibrous Component in Amyloid of Diverse Origins, 1202
Callaghan, F. R. (edited by) : Science in New Zealand, *review*, 1010
Callely, A. G., and Dagley, Dr. S. : Biosynthesis of Cell Constituents from C_2-Compounds—Metabolism of Glycine by a Pseudomonad, 1793
Callerio, Dr. Carlo, and others : Antiviral Activity of Lysozyme, 548

Calliphora erythrocephala Meig.: Neurosecretion and Intestinal Proteinase Activity in an Insect (Ellen Thomsen and Ib Møller), 1401

Calverley, A., and Rhys, D. W.: Ductility of Rhodium, 599

Calves (Early Weaned): A Relationship between some Bacteria, Protozoa and Diet in (J. Margaret Eadie, Dr. P. N. Hobson and S. O. Mann), 624

Calves (Monozygotic Twin): Threshold Values for Taste in (Dr. F. R. Bell and H. L. Williams), 345

Calves (Young): Changes in the Secretion of 20α-Hydroxypregn-4-en-3-one by the Adrenal Gland of (Dr. W. E. Balfour, Dr. R. S. Comline and R. V. Short), 467

Calvin, G., and others: Co-ordination Chemistry (Alkyl and Aryl Palladium Compounds), 1785

Calvin, Prof. Melvin: Elected a Foreign Member of the Royal Society, 1230, 1498; work of, 1498

Cambrian System?: How Old is the (Prof. C. F. Davidson), 768; (Dr. K. I. Mayne, Dr. R. St. J. Lambert and D. York), 769

Cambridge Anthropology, *review* by Dr. Rodney Needham, 1625

Cambridge Instrument Co., Ltd.: New Research Laboratory, 293

Cambridgeshire: Crowned Cranes in (Simon B. Jones and Philip E. H. Jones), 560

Cameron, Christina, and Fletcher, K.: An Iodine Compound associated with Albumin in the Plasma of Thyrotoxic Patients, 116

Cameron, Sir Roy: Appointed secretary of the Beit Memorial Trust, 1569

Camp, M. (Shuttleworth, T. H., and): Electron Microscopy of Sodium Laurate, 535

Campbell, A. G.: A Germination Inhibitor and Root-Growth Retarder in Chou Moellier (*Brassica oleracea* var.), 1263

Campbell, Dr. Dan H., and others: Passive Antibody Decay in Thyroidectomized Rabbits, 982

Campbell, Dr. J. Menzies: Apple-Scoops, 1542

Campbell, J. T., and Shalgosky, H. I.: X-Ray Spectrographic Determination of Strontium, 1481

Campolini, M., and co-workers: Co-ordination Chemistry (Stability of Metal Complexes—Heats of Formation of Ethylenediamine Complexes), 1784

Canada: Birds and Mammals of, 154

Canada (North-western): Late Tertiary Geomagnetic Field in (P. M. Du Bois), 1617

Canada (United States and), East of the 100th Meridian: A Field Guide to Reptiles and Amphibians of the (Roger Conant), *review* by A. G. C. Grandison, 958

Canadian Caesium-Beam Standard of Frequency (S. N. Kalra, R. Bailey and H. Daams), 575

Canadian Department of Agriculture: Ninth International Botanical Congress, 1502

Canadian Fire Research Laboratory: New (R. F. Legget), 653

Canadian High Polymer Forum: Ninth (National Research Council of Canada, in co-operation with the Chemical Institute of Canada), 1643

Canadian Patents and Development, Limited: Forty-first Annual Report of the National Research Council of Canada (1957-58), including the Annual Report of, 441

Canadian Society of Plant Physiologists: Election of Officers, 933

Canalization of Development and Genetic Assimilation of Acquired Characters (Prof. C. H. Waddington), 1654

Cancer: Contribution of Electron Microscopy of Viruses and Cells to the Problem of (Electron Microscope Society of America Symposium on), 1719

  Papers presented at the Conference on the Genetic Concept for the Origin of (Annals of the New York Academy of Sciences, Vol. 71), 1234

  Surmise and Fact on the Nature of (Dr. Peyton Rous), 1357

Cancer (Bronchial): Chemical Changes in Human Bronchial Epithelium and their relation to (J. Chayen, Prof. G. J. Cunningham and D. P. Winstanley), 1743

Cancer (Human Breast): Variables related to (A. Elving Anderson, Harold O. Goodman and Sheldon C. Reed), *review* by Dr. L. Foulds, 955

Cancer (Mammary): Proceedings of the Second International Symposium on, held at Perugia, 1957 (edited by Lucio Severi), *review* by Dr. L. Foulds, 955

Cancer Campaign, British Empire: Grant of £8,341 to the University of Bristol, for cancer research to be carried out in the Departments of Pathology, Physiology and Surgery, 581

Cancer Cells: Aminopeptidase Activity in (R. G. J. Willighagen and H. T. Planteydt), 263

Cancer Research: Clinical and Experimental, *review* by Dr. L. Foulds, 955

Candy, D. J., and Kilby, Dr. B. A.: Site and Mode of Trehalose Biosynthesis in the Locust, 1594

Canning, Dr. Elizabeth U.: Systematic and Experimental Studies on Protozoal Blood Parasites of Egyptian Birds, *review*, 1081

Cannon, Dr. Peter: Melting Point and Sublimation of Molybdenum Disulphide, 1612

Canny, M. J., and others: Metal-Chelating Porperties of Plant-Growth Substances, 1176

Cano Ruiz, J., and others: β-Type Interlamellar Sorption Complexes, 740

Capillaries (Glass): An Equation for the Flow of Blood, Plasma and Serum through (Dr. G. W. Scott Blair), 613

Capillary Columns (Nylon), for use in Gas–Liquid Chromatography (R. P. W. Scott), 1753

Capital Investment in the Coal, Electricity and Gas Industries: White Paper on, 1651

Cappell, Prof. D. F.: *Obituary* of Sir Robert Muir, 1363

Caputo, A., and others: Oxygen Equilibrium of Human Haemoglobin in Strong Salt Solutions, 827

Carbide: Silicon (United States Air Force Cambridge Research Center Conference on), 722

Carbohydrate Chemistry: Topics in, *review* by Prof. M. Stacey, 1219

Carbohydrate Complexes: Methanol-soluble (Ernest H. Freund and Kelvin Domovs), 1526

Carbohydrate Constituents of the Mycelium of *Penicillium chrysogenum* grown in Media with Different Sources of Carbon (Roshan J. Irani and Dr. K. Ganapathi), 758

Carbohydrates—Chemistry, Biochemistry, Physiology (edited by Ward Pigman), *review* by Prof. M. Stacey, 1079

Carbohydrates Complete, *review* by Prof. M. Stacey, 1079

Carbohydrates, Hydroxyacids and Amino-acids in Aqueous Solutions: Effects of Gamma-Radiation on some (Dr. S. A. Barker, Dr. P. M. Grant, Prof. M. Stacey and Dr. R. B. Ward), 376

Carbon: Carbohydrate Constituents of the Mycelium of *Penicillium chrysogenum* grown in Media with Different Sources of (Roshan J. Irani and Dr. K. Ganapathi), 758

C_2-Compounds: Biosynthesis of Cell Constituents from—Formation of Malate from Glycollate by *Pseudomonas ovalis* Chester (Dr. H. L. Kornberg and A. M. Gotto), 1791; Metabolism of Glycine by a Pseudomonad (A. G. Callely and Dr. S. Dagley), 1793; Formation of Glycerate from Oxalate by *Pseudomonas oxalaticus* (OX1) grown in Oxalate (J. R. Quayle and Dr. D. B. Beech), 1794

Carbon-14: Effect of Streptomycin on the Incorporation of Amino-Acids labelled with, into Ribonucleic Acid and Protein in a Cell-free System of a *Mycobacterium* (T. Erdös and Agnes Ullmann), 618

  Synthesis of Dextran Sulphate labelled with, and Tracer Experiments in the Rat (Dr. H. Weigel and Dr. K. Walton), 981

C_{18} and C_{19} *Cyclo*propane Fatty Acids: Structure of Malvalic Acid and some related (Dr. B. Craven and Prof. G. A. Jeffrey), 676

Carbon (Organic): Role of Poly-β-Hydroxybutyric Acid in the Assimilation of, by Bacteria (Prof. M. Doudoroff and Prof. R. Y. Stanier), 1440

Carbon Dioxide: Gas-Chromatographic Observation of the Reduction of, to Methane during Anaerobic Digestion (J. Chmielowski and Peter C. G. Isaac), 1120

Carbon Dioxide in *Kalanchoe blossfediana*: Dark Fixation of, in relation to Photoperiodism (Dr. G. Zabka, Prof. F. G. Gregory and Dr. J. Edelman), 1375

Carbon Monoxide Content of the Blood and other Observations on Weddell Seals (Dr. L. G. C. E. Pugh), 74

Carbon Monoxide Pressure: Behaviour of Dicobalt Octacarbonyl at Elevated Temperature and (Sol Metlin, Irving Wender and Heinz W. Sternberg), 457

Carbon Steels (Plain): Structure of Scale on (Dr. S. Garber), 1387

Carbonatite Magma: Synthetic (Prof. P. J. Wyllie and O. F. Tuttle), 770

Carbone, J. V., and others: Metabolism of Sulphobromophthalein, 469

Carbonic Acid: Selective Permeability of Living Tissues to (Dr. B. N. Halpern and R. Binaghi), 1397

Carboxyl Group of Glycine: Utilization of the, for the Synthesis of the Amino-Acids of Silk by *Bombyx mori* (Dr. S. Bricteux-Grégoire, W. G. Verly and Prof. M. Florkin), *erratum*, 294

Carcinogen (Chemical): Response of Newly Born Mice to a (Giuseppe Pietra, Kathryne Spencer and Prof. Philippe Shubik), 1689

Carcinogenesis (Ultra-violet), in Albino and Pigmented Mice receiving Furocoumarins—Psoralen and 8-Methoxypsoralen (M. A. Pathak, Prof. F. Daniels, jun., C. E. Hopkins and T. B. Fitzpatrick), 728

Carcinogenic Azo Dye: Prevention of Adaptive Formation of Tryptophan Peroxidase by a (Dr. Silvio Fiala and Anna E. Fiala), 1532

Carcinoma of the Lung (edited by J. R. Bignall), *review* by Dr. L. Foulds, 955

Carcinoma of the Uterine Cervix: Virus-like Particles in Chemically induced (Dr. M. Thiery, Dr. M. De Groodt, Prof. F. De Rom, Prof. M. Sebruyns and Dr. A. Lagasse), 694

Carcinoma Agent (Mouse Mammary): Purification of the, by means of a Fluorocarbon (Robert S. Stone and Prof. Dan H. Moore), 1275

Carcinoma Cells (Ehrlich Ascites): Energy Compensation in the Crabtree Effect with (K. H. Ibsen, E. L. Coe and Dr. R. W. McKee), 1471

Carcinus maenas Pennant: Behaviour of Sacculinized Shore Crabs (Erik Rasmussen), 479

Cardiac Activity: Nucleotide Metabolism in (Dr. Philip A. Khairallah), 181

Cardiac Muscle Fibres: Relation of Extracellular to Intracellular Potential Records from Single (Dr. E. M. Vaughan Williams), 1341

Cardiac Output in Cattle (Edward W. Fisher and Rodger G. Dalton), 829

Cardiolipin: Position of the Fatty Acids in (Dr. Marjorie G. Macfarlane and L. W. Wheeldon), 1808

Care, A. D., and others: Equilibration of Labelled Magnesium between Sheep Plasma and Red Cells, 1265

Careers Exhibition: National Education and (National Union of Teachers), 794

Careers (Scientific), in the Ministry of Supply, 651

Carey, G. C. R.: Appointed to a lectureship in preventive medicine at the Queen's University, Belfast, 86

Carlisle, Dr. C. H.: Title of reader in crystallography in the University of London (at Birkbeck College) conferred on, 794

Carlisle, Dr. D. B., and Jenkin, Dr. Penelope M.: Terminology of Hormones, 336

Carlsberg–Wellcome Travelling Research Scholarships, 1024

Carmichael, Charles M.: Remanent Magnetism of the Lake Allard Ilmenites, 1239

Carnazzo, Anthony J., and others: Target Organ Activation by Stress, 1522

Carnegie (Andrew) Silver Medal for 1958 of the Iron and Steel Institute awarded to Dr. P. Vasudevan, 930

Carnegie Institution of Washington: Year Book No. 57 (1957-1958), 1025

Carney, G. C.: Differential Response of Male and Female Adults of *Trogoderma granarium* Everts towards Sterilizing Doses of Gamma-Radiation, 338

Carotene Content of *Ulex europaeus* (Common Furze), (Dr. D. G. O'Donovan, U. O'Leary and Prof. J. Reilly), 1680

Carotenoid Pigment in *Spirobacillus cienkowskii* Metchnikoff, a Pathogen of Cladocera (J. Green), 56

Carotenoids in *Phycomyces*: Effects of Starvation and Diphenylamine on (T. N. R. Varma, Prof. C. O. Chichester and G. Mackinney), 188

Carr, Dr. Francis H.: Awarded the Society Medal for 1959 of the Society of Chemical Industry, 722

Carr, T. D., and others: Anomalous Night-Time Reception of a Major Solar Radio Burst, 597

Carrier Gas: Effect of, on Katharometer Response (W. A. Wiseman), 1321

  Effect of the, on the Sensitivity of a Thermal-conductivity Detector in Gas Chromatography (L. J. Schmauch and R. A. Dinerstein), 673; (Dr. N. H. Ray), 674

  Effect of the, on the Sensitivity of Thermal Conductivity Detectors in Gas Chromatography (Dr. B. A. Scott and Dr. A. G. Williamson), 1322

Carriers in Hereditary Galactosaemia: Detection of (Dr. Herman M. Kalckar), 1266

Carriers (Heterozygous): Detection of, in Glycogen Storage Disease of the Liver (von Gierke's Disease), (Dr. David Yi-Yung Hsia and Eva Gawronska Kot), 1331

Carron, W. J. : Industry and the Individual (Role of the Trade Unionist in relation to Productivity and the Rights of the Individual), 88
Carruthers, Dr. J. N., and others : Shorewards Upslope of the Layer of Minimum Oxygen off Bombay—its Influence on Marine Biology, especially Fisheries, 1084
Carson, A. W., and others : Electrode Potentials and Compound Formation in the Palladium–Platinum–Hydrogen System, 39, 510
Carson, John F., and Wong, Francis F. : A Colour Reaction for Thiolsulphinates, 1673
Carter, G. : Dual Pumping Speeds of some Ionization Pumps, 1619
Carter, M. V. : Chemical Destruction of Mature Perithecia of *Mycosphaerella pinodes*, 162, *erratum*, 438
Carthy, Dr. J. D. : An Introduction to the Behaviour of Invertebrates, *review* by Dr. G. A. Horridge, 4
Cartilage : Oxidative Metabolism of (Dr. Philip Person and Dr. Albert Fine), 610
  Trichloracetic Acid-insoluble Phosphate Compounds in (R. G. Whitehead and Dr. S. M. Weidmann), 876
Cartilage (Epiphyseal), during Rickets : Histochemical Changes in the (Prof. J. T. Irving), 1734
Cartilage (Human) : Ageing of (David Kaplan and Dr. Karl Meyer), 1267
Cartilage (Rachitic Rat) : Influence of Vitamin D on Synthesis of Hexosamine by (P. K. Dikshit), 334
Carvalho, Dr. Alcides : Preliminary Information on the Genetics of Ethiopian Coffees, 906
Case, James D., and others : Melatonin in Peripheral Nerve, 1821
Case, Prof. L. C. : Equilibration of *iso*Cyanates and *iso*Thiocyanates, 675
Case, Prof. L. C. (Schmoyer, L. F., and) : A Simple Synthesis of Oxetanes, 389
Casease in *Entamoeba histolytica* (Prof. Mitsuru Nakamura and Philip R. Edwards, jun.), 397
ϰ-Casein : Distribution of, in Skim Milk (Royal A. Sullivan, Margaret M Fitzpatrick and Elizabeth M. Stanton), 616
Casework : Spectral, *review* by Dr. D. J. West, 351
Cassava : A Two-stage Fermentation of (Prof. Patrick Collard and Simon Levi), 620
Cassava Brown Streak Virus : Mechanical Transmission of (R. M. Lister), 1588
Cassels, Prof. J. M. : Elected a Fellow of the Royal Society, 860
Casselton, P. J. : An Effect of Yeast Extract on the Growth of *Chlorella*, 1404
Cassen, R. H. : Awarded a Harkness Fellowship for 1959 by the Commonwealth Fund, 1093
Cassie, Dr. A. B. P. : Report for 1958 of the Wool Industries Research Association, 1781
Casson, Sir Lewis : Elected to Fellowship of the Imperial College of Science and Technology, 1161
Cast Iron Research Association, British : Retirement of Dr. J. G. Pearce from the directorship, 84
  Appointment of H. Morrogh as director, 84
  Open Days, 1434
Cat's Retinal Ganglion Cells : Recording Inhibition and Excitation in the, with Intracellular Electrodes (Dr. Torsten N. Wiesel), 264
Catabolism (Glucose), in the Mammary Gland of the Rat : Effect of Insulin and Phenazine Methosulphate on Pathways of (P. McLean), 182
Catala-Stucki, Dr. R. : Fluorescence Effects from Corals irradiated with Ultra-Violet Rays, 949
Catalysing Ester Hydrolysis : Role of Lysine in (William R. Chesbro and Prof. Leslie R. Hedrick), 994 ; (Alexander Gero), 994
Catalysis (Surface) : A Chromatographic Technique for Studying the Mechanism of (Kenzi Tamaru), 319
Catalysts (Oxide) : Effect of Thermal Neutron Irradiation on, for the Decomposition of Nitrous Oxide (Yasukazu Saito, Yukio Yoneda and Shoji Makishima), 388
Catalytic Action of Copper in the Alkaline Autoxidation of Cellulose at Low Alkali Concentration (R. I. C. Michie and Dr. S. M. Neale), 534
Catches (Trawl), from the Sierra Leone River Estuary : Seasonal and Tidal Fluctuations in the (J. C. D. Watts), 1748
Catechol in Human Urine : Excretion of (Prof. U. S. von Euler and F. Lishajko), 1123
Cater, Dr. D. B., and Weiss, Dr. L. : Measurements of Oxygen Tension in the Tissues of Mice cooled to 1°C., 1521
Cathode Inclusions : Effect of, on Electrical Discharges (P. C. L. Pfeil and L. B. Griffiths), 1481
Cathode-Ray Tube : The Ferranti 5/71 *CM* Micro-Spot, 1642
Cathode Spots (Vacuum Arc) : An Effect of Oxide Layers on the Behaviour of (H. Wroe and R. H. Alderson), 1544
Cathode (Hollow-) Emission of the A10 Spectrum (V. Wilson Goodlett and K. Keith-Innes), 243
Cations (Alkali) : Absorption of, by Plant Tissue Cultures (Dr. J.-F. Sutcliffe and E. R. Counter), 1513
Catskill Delta : *Spirifer disjunctus*, its Evolution and Paleoecology in the (Hugo Greiner), *review* by Dr. H. M. Muirwood, 959
Cattala, L. (Roche, Dr. A., and) : Remanent Magnetism of the Cretaceous Basalts of Madagascar, 1049
Cattell, Prof. Raymond B. : Personality and Motivation Structure and Measurement, *review* by Prof. M. D. Vernon, 140
Cattle : Bloat in (Dr. M. J. Head), 757
  Breeding 10,000,000 (Milk Marketing Board), 1641
  Cardiac Output in (Edward W. Fisher and Rodger G. Dalton), 829
  β-Globulin Polymorphism and Early Foetal Mortality in (Dr. G. C. Ashton), 404
Cattle (British) : The Nematodes *Ostertagia lyrata* Sjöberg, 1926, and *Trichostrongylus longispicularis* Gordon, 1933, in (Dr. J. H. Rose), 1745
Cattle in Kenya : Lumpy Skin Disease of (M. L. Burdin and J. Prydie), 949
Cattle recovering from Foot-and-Mouth Disease : Changes in Specificity and Electrophoretic Mobility of the Precipitating Antibodies present in the Serum of (F. Brown and J. H. Graves), 1688
Caudal Regeneration in some Errant Polychaetes : Role of the Supra-oesophageal Ganglion during the Early Stages of (Dr. R. B. Clark and M. E. Clark), 1834
Causes (Possible), of Geomagnetic Fluctuations having a 6-Sec. Period (H. J. Duffus, J. A. Shand and Sir Charles Wright), 1479, *erratum*, 1783
Cave Deposits : The Transvaal Ape-Man-bearing (C. K. Brain), 1433
Caves (Niah Great) : 'Bat Erosion' at (Tom Harrisson and Lord Medway), 971
Cayless, M. A. : Gas Discharges (Factors governing the Shape and Size of the Glow and the Electron and Ion Currents at the Cathode Surface), 92
Cell : Effect of X-Rays on the (Dr. M. Silha), 1531
  Physical and Chemical Exploration of the, *review* by Dr. R. Barer, 1355
Cell (Gastric Parietal) : Functional Changes in the Vacuole-containing Bodies of the (A. D. Hally), 408
Cell (Human Red) : Haemoglobin and 'Apparent Protein' in the (Dr. Eric Ponder), 1330
Cell Constituents from C_2-Compounds : Biosynthesis of—Formation of Malate from Glycollate by *Pseudomonas ovalis* Chester (Dr. H. L. Kornberg and A. M. Gotto), 1791 ; Metabolism of Glycine by a Pseudomonad (A. G. Callely and Dr. S. Dagley), 1793 ; Formation of Glycerate from Oxalate by *Pseudomonas oxalaticus* (OX1) grown in Oxalate (J. R. Quayle and Dr. D. B. Keech), 1794
Cell Dimensions : Variation in Etch Behaviour of Jacobsite with Different (Dr. Supriya Roy), 1256
Cell Division : Phagocytosis and (Klaus G. Bensch, Stanley Simbonis, Rolla B. Hill, jun., and Prof. Donald W. King), 476
Cell 'Ghosts' (Red) : Preparation and the Haemoglobin Content of (Helen M. Anderson and Dr. Joseph C. Turner), 112
Cell Growth and the Development of Tumours (Anna Kane Laird and A. D. Barton), 1655
Cell Haemolysates (Red) : Demonstration of Small Components in, by Starch-gel Electrophoresis (Dr. Phaedon Fessas and N. Mastrokalos), 1261
Cell Material (Insoluble), derived from *Brucella* : Immunizing Properties of (J. Markenson, D. Sulitzeanu and Prof. A. L. Olitzki), 1693
Cell-Nuclei in the Adrenal Medulla : Deoxyribonucleic Acid Content of the, after Exposure to Low Temperatures (L. Leeman), 1188
Cell-Wall Composition of *Leptotrichia* spp. (Dr. G. H. G. Davis and A. C. Baird-Parker), 1206
Cell Walls (Aberrant), and of Spores : Formation of, by the Growing Yeast Protoplast (A. A. Eddy and D. H. Williamson), 1101
Cell-free System of *Mycobacterium* : Effect of Streptomycin on the Incorporation of Amino-Acids labelled with Carbon-14 into Ribonucleic Acid and Protein in a (T. Erdös and Agnes Ullmann), 618
Cells : Contribution of Electron Microscopy of Viruses and, to the Problem of Cancer (Electron Microscopy Society of America Symposium on), 1719
  A Correlation between Iodine Permeability and the Gram Characteristic of (Prof. J. W. Bartholomew, Thomas Cromwell and Harold Finkelstein), 123
  The Motility of Muscle and (Prof. Hans H. Weber), *review* by J. R. Bendall, 278
Cells (Ascites Tumour) : Micro-Electrode Penetration of (B. M. Johnstone), 411
Cells (Cancer) : Aminopeptidase Activity in (R. G. J. Willighagen and H. T. Planteydt), 263
Cells (Cat's Retinal Ganglion) : Recording Inhibition and Excitation in the, with Intracellular Electrodes (Dr. Torsten N. Wiesel), 264
Cells ('Chloride-Secretory'), in the Gills of Teleosts (Gwyneth Parry, and F. G. T. Holliday and J. H. S. Blaxter), 1248
Cells (Chromaffin) : A New Type of, probably storing Dopamine (Bengt Falck, Prof. Nils-Åke Hillarp and Alf Torp), 267
Cells (Circulating), of Infectious Mononucleosis : Incorporation of Thymidine labelled with Tritium by (Dr. F. Gavosto, A. Pileri and G. Maraini), 1691
Cells (Ehrlich Ascites Carcinoma) : Energy Compensation in the Crabtree Effect with (K. H. Ibsen, E. L. Coe and Dr. R. W. McKee), 1471
Cells (Epidermal), in Petioles of Strawberry : Effect of Gibberellic Acid on Length and Number of (C. G. Guttridge and P. A. Thompson), 197
Cells (Freshly Harvested), of a Brewer's Yeast : Endogenous Metabolism of (V. E. Chester), 902
Cells (Ganglion), in the Retina of Anurans : Number of Fibres in the Optic Nerve and the Number of (Dr. H. R. Maturana), 1406
Cells (Human Red) : Effect of Ouabain on Sodium Flux in (Thomas J. Gill and Prof. A. K. Solomon), 1127
Cells (Isolated Spleen), transferred to Recipients in Absence of Homotransplantation Reaction : Antibody Formation by (Dr. Z. Trnka and I. Říha), 546
Cells (Lens), of the Calf in Continuous Culture (Dr. J. van der Veen and C. F. A. Heyen), 1137
Cells (Living) : Prevention of Freezing Damage to, by Dimethyl Sulphoxide (Dr. J. E. Lovelock and Dr. M. W. H. Bishop), 1394
Cells (Mammalian) : Two Types of Ribonucleoprotein in the Nucleolus of (Dr. Robert Love and Dr. T. P. Bharadwaj), 1453
Cells (Mammalian), irradiated *in vivo* : A Survival Curve for (Dr. H. B. Hewitt and C. W. Wilson), 1060
Cells (Mast) : Analysis of, by means of Polarization Microscopy (Prof. Leslie Horváth), 1067
  Differences in Mechanism in Staining Reactions for (Dr. Harold M. Fullmer), 1274
  Leucine Aminopeptidase Activity in (Dr. O. Braun-Falco and Dr. K. Salfeld), 51
Cells (Normal and Malignant), cultivated in Synthetic Media : Glutamine Metabolism of (Arthur E. Pasieka and Dr. Joseph F. Morgan), 1201
Cells (Pineal Eye Sensory) : Ultrastructure of (Dr. W. Steyn), 764
Cells (Red) : Equilibration of Labelled Magnesium between Sheep Plasma and (A. D. Care, D. C. Macdonald and B. Nolan), 1265
  Impairment of Viral Haemagglutination of, after Treatment with Formalin (F. E. Buckland), 1276
Cells (Red), of the Mouse after Treatment with Formalin : Increase of Viral Haemagglutinability of (B. Fauconnier and D. Barua), 629
Cells (Red Blood) : Rate of Exchange of Phosphate in—Effect of Thyroid Hormones (A. M. Ermans and Prof. P. A. Bastenie), 679
Cells (Reticular) : Re-utilization of Lymphocyte Remnants by (Dr. M. Hill), 1059
Cells (Tissue Culture), stained with Acridine Orange : Fluorescence of (U. N. Joshi and Dr. K. S. Korgaonkar), 400
Cells (Transferred) : Presence of Antigen—a Factor determining the Duration of Antibody Formation by (Dr. J. Sterzl), 547
Cells (Yeast) : Life Span of Individual (Robert K. Mortimer and John R. Johnston), 1751
Cells and Spores (Vegetative), of *Bacillus cereus* and *Bacillus megaterium* : Differences in Cyst(e)ine Content between (Vladimír Vinter), 998

Cellulose : Synthesis of, in Ethanol Extracts of *Acetobacter xylinum* (Dr. J. Ross Colvin), 1135
Cellulose at Low Alkali Concentration : Catalytic Action of Copper in the Alkaline Autoxidation of (R. I. C. Michie and Dr. S. M. Neale), 534
Cellulose containing Methyl Groups : Changes produced in Serum Lipoproteins of Dogs by (Margaret M. Fröhlich, V. Balázs, K. Kovács and A. Benkö), 1119
Cellulose-reactive Dyes : Labelling of Proteins with (Dr. R. Hess and Dr. A. G. E. Pearse), 260
Cellulose Acetate as a Medium for Immuno-Diffusion (R. Consden and J. Kohn), 1512
Cellulose Acetate Membranes suitable for Osmotic Measurements (M. F. Vaughan), 43
Cellulose Acetate Membranes used for Zone Electrophoresis : Regeneration of (Dr. S. Jacobs), 1326
Cellulosics (Walter D. Paist), *review* by Dr. S. H. Pinner, 851
Cement (Hardened Portland), during Testing : Errors caused by Partial Drying of (Dr. K. M. Alexander), 885
Centenaries of 1959 : Scientific (Joan M. Eyles), 12
Centenary of the death of Isambard Kingdom Brunel : Exhibition to commemorate the (Engineering Laboratory, Cambridge), 1164
Centenary of the Formulation of the Theory of Evolution by Charles Darwin and Alfred Russel Wallace and the Bicentenary of the publication of the tenth edition of the 'Systema Naturae' by Linnaeus (Congress in Singapore to celebrate the), 723
Centenary of the Royal Society of Victoria, 86
Central Advisory Water Committee : Fourth Meeting, 152
  Appointment of Prof. J. Proudman as chairman of the Sub-Committee on the Demand for Water, 152
Central Africa : Scientific Research in, 1718
Central Fuel Research Institute, India : Symposium on the Nature of Coal, 86, 1438
Central Nervous System : Persistence of Cholesterol-4-^{14}C in the (Dr. A. N. Davison and Martha Wajda), 1606
Central Organisation for Defence (White Paper on), 1483
Centre d'Etudes Nucléaires de Grenoble, 858
Centre Européen des Federations de l'Industrie Chimique, 1368
Century of Biological Research (Illinois Natural History Survey, Bulletin, Vol. 27), 1233
Cephalopods : Cephalotoxin, the Crab-paralysing Agent of the Posterior Salivary Glands of (Dr. F. Ghiretti), 1192
Cephalotoxin, the Crab-paralysing Agent of the Posterior Salivary Glands of Cephalopods (Dr. F. Ghiretti), 1192
Ceramic Materials (Fired) : Adsorption and Desorption of Moisture in (F. Vaughan and A. Dinsdale), 600
Cercaria : A New Leech-infesting, from Duddingston Loch, Edinburgh (Prof. M. B. Lal), 697
Cereal Research Station (German) : Annual International Starch Convention, 510
Cerebellum : Physiology of the, *review* by Dr. C. G. Phillips, 954
  The Physiology and Pathology of the (Prof. Robert Stone Dow and Prof. Giuseppe Moruzzi), *review* by Dr. C. G. Phillips, 954
Cerebral Circulation and Metabolism in a Pyridoxine-dependent Child : Effects of Pyridoxine Withdrawal on (Dr. Louis Sokoloff, Dr. Niels A. Lassen, Dr. Guy M. McKhann, Dr. Donald B. Tower and Dr. Wayne Albers), 751
Cerebral Cortex : Electron Microscopy of Synaptic Contacts on Dendrite Spines of the (Dr. E. G. Gray), 1592
  Recurrent Inhibition in (Dr. Roger M. Morrell), 979
CERN (European Organization for Nuclear Research) : Annual Report for 1957, 21
  International Conference on High Energy Accelerators and Instrumentation, 1783
Cerrai, E., and Gadda, F. : Separation of Mono-*n*-butyl Phosphate and Di-*n*-butyl Phosphate by means of Ion Exclusion, 1528
Ceruloplasmin : Preparation of (Dr. M. Steinbuch and M. Quentin), 323
Cervix (Uterine) : Virus-like Particles in Chemically induced Carcinoma of the (Dr. M. Thiery, Dr. M. De Groodt, Prof. F. De Rom, Prof. M. Sebruyns and Dr. A. Lagasse), 694
Chabanaud, Dr. Paul : *Obituary* by Dr. E. Trewavas, 1496
Chabbi, Lamine : The Role of the Scholar in Society, 1772
Chaffinch (Common), *Fringilla coelebs* Linn. : Singing Pattern of the (D. R. Barber), 129
Chain, Prof. E. B., and others : Penicillin Derivatives of *p*-Aminobenzylpenicillin, 180, *erratum*, 224
Chain Fracture : Estimation of, during the Cross-linking of Rubber Hydrocarbons by High-Energy Radiation (Dr. L. Mullins and Dr. D. T. Turner), 1547
α-Chains of Adult and Foetal Human Haemoglobins : Identity of the (J. A. Hunt), 1373
Chairs and Tables (Office) : Anatomical, Physiological and Anthropometric Principles in the Design of (Dr. W. F. Floyd and Dr. D. F. Roberts), 1022
Chaklader, A. C. D., and Roberts, Prof. A. L. : Sintering of Quartz Crystal, 1252
Chakrabartty, S. K., and others : The Nature of Coal (Pyrolysis and its relation to the Structural Parameters of Coal), 1439
Challenger Society : Grants for research in Marine Biology or Oceanography, 1368
Chalmers, Dr. J. N. Marshall, and Shinton, N. K. : Effect of D-Sorbitol on the Absorption of Orally Administered Vitamin B_{12}, 120
Chamberlin, Prof. Ralph V., and Gertsch, Willis J. : The Spider Family Dictynidae in America North of Mexico, 1170
Champion, Sir Harry : Retirement as professor of forestry in the University of Oxford, 578 ; work of, 578
  Progress in British Forestry, 1100
  Forestry in the United Kingdom, 1238
Chance and Skill in Gambling : Preferences for Different Combinations of (Prof. John Cohen and C. E. M. Hansel), 841
Chance-Pilkington Optical Works : Radiation-absorbing Glasses, 292
Chandler, Dr. B. V., and Swain, Dr. T. : Separation of Anthocyanins from Plant Extracts, 989
Change of Colour in Frogs : Serotonin and (Dr. K. G. Davey), 1271
Change in Permeability effected by Lipid-soluble Analogues of Acetylcholine : Distinction between Sodium and Potassium in (Dr. Wolf D. Dettbarn), 465
Change (Dietary), in *Harmolita hyalipenne* Walker : Facultative Parasitism and (R. Bailey), 341
Change (Social) : Social Policies and, *review* by M. P. Hall, 1147
Changes in the Electron Spin Resonance Spectrum of Glycine with Increasing Doses of Radiation (Dr. J. W. Boag and A. Müller), 831
Changes in the Group A Antigen in a Case of Leukaemia (Dr. E. R. Gold, Dr. Geoffrey H. Tovey, W. E. Benney and F. J. W. Lewis), 892
Changes in the Inclination of Satellite Orbits to the Equator (R. H. Merson, D. G. King-Hele and R. N. A. Plimmer), 239
Changes in Lymphocytes during Antibody Production (K. W. Keohane and W. K. Metcalf), 195
Changes in Œstrogen Titre in Stored Urine (Y. A. Leon, R. D. Bulbrook and F. C. Greenwood), 189
Changes in the Osteoblastic and Mitochondrial Population of Ageing Periosteum (Dr. E. A. Tonna and Dr. N. Pillsbury), 337
Changes in pH and Temperature in Poultry Breast Muscles at Slaughter (F. E. Peters and J. W. Dodge), 687
Changes in the Secretion of 20α-Hydroxy-pregn-4-en-3-one by the Adrenal Gland of Young Calves (Dr. W. E. Balfour, Dr. R. S. Comline and R. V. Short), 467
Changes produced in Serum Lipoproteins of Dogs by Cellulose containing Methyl Groups (Margaret M. Fröhlich, V. Balázs, K. Kovács and A. Benkö), 1119
Changes in Serum Transaminase Activity following Myocardial Damage due to Lymphatic Congestion (M. Földi, Dr. P. Braun, Dr. M. Papp and Dr. I. Horváth), 1333
Changes in Specificity and Electrophoretic Mobility of the Precipitating Antibodies present in the Serum of Cattle recovering from Foot-and-Mouth Disease (F. Brown and J. H. Graves), 1688
Changes in Transition Probability due to the Interaction of Rotation and Vibration in Diatomic Band Spectra (R. C. M. Learner and Dr. A. G. Gaydon), 242
Changes (Chemical), in Human Bronchial Epithelium and their relation to Bronchial Cancer (J. Chayen, Prof. G. J. Cunningham and D. P. Winstanley), 1743
Changes (Functional), in the Vacuole-containing Bodies of the Gastric Parietal Cell (A. D. Hally), 408
Changes (Histochemical), in the Epiphyseal Cartilage during Rickets (Prof. J. T. Irving), 1734
Changes (Seasonal), in the Brain-case of the Common Shrew (*Sorex araneus* L.), (Peter Crowcroft and Jean M. Ingles), 907
Changes (Structural Chromosome) : Induction of, by Visible Light (Dr. B. A. Kihlman), 976
Changing Industry (British Institute of Management Conference on), 655
Changing Vision (Man's), of the Universe : The Sleepwalkers—a History of (Arthur Koestler), *review* by Dr. A. R. Hall, 1419
Chapelcross Nuclear Power Station, 649 ; (J. C. C. Stewart), 1361
Chapman, D., and others : Liquid/Solid Content of Fats, 44
Chapman, Prof. S. : Space Research (The Aurora), 362
Chapman, Victor, and others : Genetic Control of Chromosome Pairing in Intergeneric Hybrids with Wheat, 1241
Chappell, Dr. J. B., and Greville, Dr. G. D. : Inhibition of Electron Transport and the Swelling of Isolated Mitochondria, 1525
  Effects of 2:4-Dinitrophenol and other Agents on the Swelling of Isolated Mitochondria, 1737
Character (Possible), for the Identification of Sharks : Red Muscle as a (Olaf R. Braekkan), 556
Characteristic Wealden Ferns in the Jabalpur Series : Occurrence of Two (Dr. M. N. Bose and Sukh Dev), 130
Characteristic (Gram), of Cells : A Correlation between Iodine Permeability and the (Prof. J. W. Bartholomew, Thomas Cromwell and Harold Finkelstein), 123
Characteristics of the Antarctic Ice-Sheet (Royal Astronomical Society and the British Glaciological Society Geophysical Discussion on), 1575
Characteristics of the Bartonellas, *review* by Dr. A. Lwoff, 207
Characteristics (Phase), of Radio Signals received via the Ionosphere (D. W. Morris and C. J. Hughes), 310
Characterization of Molecular Weight Distributions by a Viscometric Method (Dr. P. F. Onyon), 1670
Characterization of a Second Yellow Compound from *Drosophila melanogaster* (Dr. H. S. Forrest, Dolph Hatfield and Dr. C. Van Baalen), 1269
Characters (Acquired) : Canalization of Development and Genetic Assimilation of (Prof. C. H. Waddington), 1654
Characters (Production), in the Fowl : Effect of Controlled Lighting on (J. C. Bowman and J. D. H. Archibald), 1138
Charge (Tubular), of Explosive : Advance Detonation in a (Dr. D. W. Woodhead), 1756
Charges (Surface), produced on Insulators by Short- and Long-time Ionization (Dr. Stanley I. Renolds), 671
Charnock, Dr. H. : Turbidity Currents, 657
Chars (Low-Temperature) : Smoke Emission of (W. N. Adams, A. F. Gaines, D. H. Gregory and G. J. Pitt), 33 ; (Prof. Morris W. Travers), 1321
Charvát, Prof. J., and others : Fractionation of Brain Extracts for Acid Phosphatase-elevating Activity, 473
Chaston, I. R. M. : Awarded the William Frecheville Student's Prize of the Institution of Mining and Metallurgy, 1499
Chatterjee, Prof. S. P. : Awarded the Murchison Grant of the Royal Geographical Society, 292
Chayen, J., and others : Chemical Changes in Human Bronchial Epithelium and their relation to Bronchial Cancer, 1743
Chelate Compounds (Metal), of β-Diketones : Metal–Oxygen Stretching Frequencies in the (Kazuo Nakamoto, Paul J. McCarthy and Arthur E. Martell), 459
Chelating Agents : Reaction of some Silicates with (Dr. D. A. Sutton, M. D. Middleton and R. A. F. Body), 99, *erratum*, 1719
Chelometric Titrations (Semi-Micro) : A New Sensitive Indicator for (Prof. Robert H. Maier), 461
Chelsea College of Science and Technology : New Building (N. M. H. Lightfoot), 1722
Chemical Analysis : Magnetometric Titration—a New Method of (Dr. M. S. Blackie and Dr. V. Gold), 1804
Chemical Aspects of the Production and Use of Grass (Dublin and District Section and the Agriculture Group of the Society of Chemical Industry Symposium on), 1783

Chemical Basis for the Classification of Glume Colour in Nigerian Cultivated Sorghums (W. R. Stanton, T. B. Miller and D. L. Curtis), 807
Chemical Carcinogen : Response of Newly Born Mice to a (Giuseppe Pietra, Kathryne Spencer and Prof. Philippe Shubik), 1689
Chemical Changes in Human Bronchial Epithelium and their relation to Bronchial Cancer (J. Chayen, Prof. G. J. Cunningham and D. P. Winstanley), 1743
Chemical Composition of Tektites (Dr. Brian Mason), 254 ; (Prof. Harold C. Urey), 1114
Chemical Destruction of Mature Perithecia of *Mycosphaerella pinodes* (M. V. Carter), 162, *erratum*, 438
Chemical Engineering at Cambridge, 719
Chemical Engineering : Fluid Systems in, *review* by Prof. J. M. Coulson, 492
Chemical Engineering Practice (edited by Herbert W. Cremer and Trefor Davies), Vol. 5, Fluid Systems I, *review* by Prof. J. M. Coulson, 492
Chemical Engineers, Institution of, and others : Joint Symposium on Instrumentation and Computation in Process Development and Plant Design, 652
Chemical Excitation of Spinal Neurones (Dr. D. R. Curtis, J. W. Phillis and Dr. J. C. Watkins), 611
Chemical Exploration of the Cell : Physical and, *review* by Dr. R. Barer, 1355
Chemical Industry, Society of : Society Medal for 1959 awarded to Dr. Francis H. Carr, 722
  Appointment of Dr. E. J. Solvay as president, 1024
Chemical Industry, Society of (Dublin and District Section and the Agriculture Group) : Symposium on Chemical Aspects of the Production and Use of Grass, 1783
Chemical Institute, Royal Australian : H. G. Smith Memorial Medal awarded to Prof. S. J. Angyal, 794
Chemical Institute of Canada (National Research Council of Canada, in co-operation with the) : Ninth Canadian High Polymer Forum, 1643
Chemical Laboratory (National), Teddington : Appointment of Dr. J. S. Anderson as director, 1719
Chemical Notation : A Proposed International (prepared by the Commission on Codification, Ciphering and Punched Card Techniques of the International Union of Pure and Applied Chemistry), tentative version subject to revision, *review* by Dr. E. H. Rodd, 960
Chemical Radiation Damage : Thermal Annealing of (Dr. A. G. Maddock and S. R. Mohanty), 86
Chemical Reactions : Electronic Theory and (R. W. Stott), fourth edition, *review* by Dr. R. I. Reed, 968
Chemical Research Laboratories of the Commonwealth Scientific and Industrial Research Organization, Australia, 228
Chemical Society : Corday—Morgan Medal and Prize for 1957 awarded to Prof. G. W. Kenner, 792
  To publish a cover-to-cover translation of the Russian *Zhurnal neorganicheskoi Khimii*, 1092
  Symposium on Fluorine Chemistry, 1304
  Presidential Address (Prof. H. J. Emeléus), 1785
Chemical Society (sponsored by the International Union of Pure and Applied Chemistry) : Fourth International Conference on Co-ordination Chemistry, 1784
Chemical Society, American : Monograph Series No. 138, Aliphatic Fluorine Compounds (A. M. Lovelace, Douglas A. Rausch and William Postelnek), *review* by Prof. R. N. Haszeldine, 139
  1958 Pittsburgh Award of the Pittsburgh Section awarded to Dr. Max A. Lauffer, 224
  1959 Dexter Award awarded to Prof. John Read, 1304
Chemical Synthesis of Hexose and Hexosamine Sulphates (Dr. A. G. Lloyd), 109
Chemical and Biological Examination (Bacteriological,), of the London Waters for the Years 1955-56 : Thirty-seventh Report on the Results of the (E. Windle Taylor), 798
Chemically Induced Breast Tumours in Mice of the *IF* Strain : Local Inhibition by Lactation of (June Marchant), 629
Chemically Induced Carcinoma of the Uterine Cervix : Virus-like Particles in (Dr. M. Thiery, Dr. M. De Groodt, Prof. F. De Rom, Prof. M. Sebruyns and Dr. A. Lagasse), 694
Chemicals on Insects : Methods of Testing (edited by Harold H. Shepard), Vol. I, *review* by Dr. W. A. L. David, 352
Chemicals on Plants : Separation of Specific and Non-Specific Effects of (Prof. T. J. Muzik and J. M. Lawrence), 482
Chemicals (Toxic), released from a Low-flying Aircraft : Drift of (D. Yeo, N. B. Akesson and H. H. Coutts), 131
Chemicals and Insects, *review* by Dr. W. A. L. David, 352
Chemicals, Oil and Gas from Coal (Ministry of Power to set up a Committee on), 1162
Chemist of the Brain : Thudichum—(Prof. David L. Drabkin), *review* by H. W. Kosterlitz, 568
Chemistry at Edinburgh, 151
Chemistry in relation to Medicine at Edinburgh, 1567
Chemistry in Schools, *review* by Prof. M. J. S. Dewar, 566
Chemistry, Royal Institute of : Symposium on Separation Processes in Analytical Chemistry, 934
  Election of Officers, 1234
Chemistry, Royal Institute of (London Section), and others : Debate on the motion 'That the Education of our Future Rulers should be primarily in the Sciences rather than in the Humanities,' 510, 1235
Chemistry : Co-ordination (Chemical Society, sponsored by the International Union of Pure and Applied Chemistry, Fourth International Conference on), 1784
  The Father of, *review* by Dr. R. E. W. Maddison, 850
  Fluorine (Chemical Society Symposium on), 1304
  Low Temperature Physics and—Proceedings of the Fifth International Conference on Low Temperature Physics and Chemistry, Madison, 1957 (edited by Joseph R. Dillinger), *review* by Dr. K. Mendelssohn, 1150
  Organic Fluorine, *review* by Prof. R. N. Haszeldine, 139
  Polymer, *review* by Prof. C. E. H. Bawn, 637
  Radiation (Bradford Chemical Society, the Department of Chemical Technology of the Bradford Institute of Technology and the Yorkshire Council for Further Education Symposium on), 18
  Ramsay Memorial Fellowships for Advanced Students of, 367
  Seventh Latin American Congress of (Mexico), 294
  The Teaching of (N. F. Newbury), second edition, *review* by Prof. M. J. S. Dewar, 566
Chemistry of Condensed Tannins (Plant Phenolics Group Discussion on), 1168
Chemistry of Natural and Synthetic Rubbers (Prof. Harry L. Fisher), *review* by Dr. W. J. S. Naunton, 779
Chemistry of Propellants (Advisory Group for Aeronautical Research and Development of NATO Meeting on), 1094
Chemistry of the Rare Radioelements—Polonium–Actinium (Dr. K. W. Bagnall), *review* by G. R. Hall, 962
Chemistry of the Steroids (Prof. Charles W. Shoppee), *review* by Dr. E. Stedman, 636
Chemistry of Tobacco Smoke : Bibliography on the, 1434
Chemistry (Analytical) : Separation Processes in (Royal Institute of Chemistry Symposium on), 934
Chemistry (Analytical), Society for : Election of Officers, 1024
Chemistry (Carbohydrate) : Topics in, *review* by Prof. M. Stacey, 1219
Chemistry (Clinical) : Advances in (edited by Dr. Harry Sobotka and Dr. C. P. Stewart), Vol. I, *review* by Prof. J. N. Davidson, 5
Chemistry (Detergent) : Some Alkyl-Aryl Sodium Sulphonates as Standard Substances in (E. Q. Laws and W. Hancock), 1473
Chemistry (Industrial), Salters' Institute of : Appointment of Prof. A. R. J. P. Ubbelohde as director, 1094
Chemistry (Medicinal and Pharmaceutical), Journal of, Vol. I, No. 1, 1304
Chemistry (Organic), at Birmingham, 791
Chemistry (Organic), at Perth, Australia, 578
Chemistry (Organic) : Electronic Theories of (John William Baker), *review* by Dr. R. I. Reed, 777
  An Introduction to Electronic Theories of (G. I. Brown), *review* by Dr. R. I. Reed, 279
  Names and Ciphers in, *review* by Dr. E. H. Rodd, 960
  Nomenclature of, 1957 (International Union of Pure and Applied Chemistry), *review* by Dr. E. H. Rodd, 960
  Recent Progress in (International Symposium on, Mexico), 294
  Theoretical Principles of (Prof. Walter Hückel), Vol. 2, translated from the corrected seventh German edition by Prof. F. H. Rathmann, *review* by Dr. P. B. D. de la Mare, 852
Chemistry (Physical), of High Polymers (Dr. Maurice L. Huggins), *review* by Prof. C. E. H. Bawn, 637
Chemistry (Protein) : Advances in (edited by C. B. Anfinsen, Jr., M. L. Anson, Kenneth Bailey and John T. Edsall), Vol. 12, *review* by Dr. M. F. Perutz, 1290
  More, *review* by Dr. M. F. Perutz, 1290
  Recent Advances in (Department of Chemistry, Biology and Geology of the Kingston Technical College Postgraduate Lecture Course on), 86
Chemistry (Pure and Applied) : Seventeenth International Congress of, 1368
Chemistry (Pure and Applied), International Union of : Formation of a Special Group under the auspices of the Analytical Chemistry Section, to make recommendations for a standard terminology in Gas Chromatography, 722
  Nomenclature of Organic Chemistry, 1957, *review* by Dr. E. H. Rodd, 960
  A Proposed International Chemical Notation (prepared by the Commission on Codification, Ciphering and Punched Card Techniques), tentative version subject to revision, *review* by Dr. E. H. Rodd, 960
Chemistry (Pure and Applied), International Union of (Commission on Geochemistry) : Symposium on Geochemistry, 1719
Chemistry (Pure and Applied), International Union of (organized by the Chemical Society and sponsored by the) : Fourth International Conference on Co-ordination Chemistry, 1784
Chemistry (Quantum) : Chemistry and (Quantum Chemistry Group, Uppsala, Discussion on), 158
Chemistry (Seventeenth-Century) : Robert Boyle and (Prof. Marie Boas), *review* by Dr. R. E. W. Maddison, 850
Chemistry (Structural), of Promethium (M. Bruno and Prof. U. Croatto), 601
Chemistry and Quantum Chemistry (Quantum Chemistry Group, Uppsala, Discussion on), 158
Chemists (Cosmetic), Society of : British Congress of Cosmetic Science, 934
Chemists (Cosmetic) : International Federation of Societies of (Formation of an), 1366
Chemists (European), American Society of : Neuberg Medal awarded to Dr. H. Albert Barker, 1304
Chemostat : Bacterial Population Studies in the, *review* by Dr. A. C. R. Dean, 424
  The Dynamics of Bacterial Populations maintained in the (Hermann Moser), *review* by Dr. A. C. R. Dean, 424
Chemotherapy of Parasitic Diseases (Parasitology Group of the Institute of Biology Discussion on), 1029
Chemotherapy (The New), in Mental Illness (edited by Dr. Hirsch L. Gordon), *review* by Dr. Marthe Vogt, 1007
Cheng, C. H., and others : Low-temperature Specific Heats of Body-centred Cubic Chromium–Iron and Chromium–Manganese Alloys, 315
Cheong, L., and others : Incorporation of 5-Iodouracil labelled with Iodine-131 into the Deoxyribonucleic Acid of Human Leukaemic Leucocytes following *in vivo* Administration of 5-Iododeoxyuridine labelled with Iodine-131, 1686
Cherry, Prof. Colin : Economics of Telecommunication, *review*, 778
  Stereophonic Sound Recording, Reproduction and Broadcasting, 1720
Chesbro, William R., and Hedrick, Prof. Leslie R. : Role of Lysine in catalysing Ester Hydrolysis, 994
Chessin, Prof. Meyer (Taylor, John J., and) : Photochemical Reduction of Blue Tetrazolium by Isolated Chloroplasts, 626
Chester, G. V.: Problems of Collective Motion in Physics (Liquid Helium and Superconductivity), 866
Chester, V. E. : Endogenous Metabolism of Freshly Harvested Cells of a Brewer's Yeast, 902
Chesters, Dr. Kathleen: Palaeoecology (Tertiary Floras of the Coastal Parts of Kent, Sussex, Hampshire, Dorset and Devon), 1370
Chichester, Prof. C. O., and others: Effects of Starvation and Diphenylamine on Carotenoids in *Phycomyces*, 188
Chick (Growing) : Relative Rates of Liver Storage of Pure α-, β-, γ- and δ-Tocopherols in the (T. W. Griffiths), 1061
Chick Embryo : Oxidative Phosphorylation in the (Prof. Wiktor W. Nowinski and William C. Mahaffey), 45

Chick Embryos : Sodium, Potassium, Calcium and Chloride Ion Contents and Protein Fractions in the Fluids of (Dr. Aleksandra Smoczkiewiczowa), 1260
Chick Liver : Vitamin B_{12} and Biosynthesis in (Vitamin B_{12} and Protein Biosynthesis), (Dr. M. J. Fraser and Dr. E. S. Holdsworth), 519
Chicken Embryos : Effect of Amniotic Fluid on Inhibition of Growth by Cortisone in (Dr. P. de Franciscis and Prof. W. Landauer), 617
Chicken Lumi- and Meta-Iodopsin (Action of Light on Visual Pigments), (Dr. Ruth Hubbard and Dr. Allen Kropf), 448
Child, H. C. : Awarded the Williams Prize for 1958 of the Iron and Steel Institute, 930
Child : Television and the (Dr. Hilde T. Himmelweit, A. N. Oppenheim and Pamela Vince), *review*, 780
Child (Pyridoxine-dependent) : Effects of Pyridoxine Withdrawal on Cerebral Circulation and Metabolism in a (Dr. Louis Sokoloff, Dr. Niels A. Lassen, Dr. Guy M. KcKhann, Dr. Donald B. Tower and Dr. Wayne Albers), 751
Children (Sixth-form) : Lectures for (Royal Institution), 294
Childs, Prof. John L. : Education in the Age of Science, 1436
Chilean Coast : Relationship between the Hake Fishery and a Southerly Sub-surface Return Flow below the Peru Current off the (Dr. Wilhelm Brandhorst), 1832
Chilton, D. : Inertial Navigation, 64
Chimera (Rat–Mouse) : Life-Span of Rat and Mouse Erythrocytes in the (Dr. Joan W. Goodman and Dr. L. H. Smith), 1833
Chimie : Fifth International Salon de la, 1434
Chimneys (Power Station) : Pollution from, 85
Chinese Rocks : Some Palaeomagnetic Investigations on (Dr. Chang Wen-you and Dr. A. E. M. Nairn), 254, 652
Chinese Scientific Literature (Lending Library Unit of the Department of Scientific and Industrial Research collection of), 932
Chirnside, R. N. : Elected president of the Society of Analytical Chemistry, 1024
Chisholm, A. W. J. : Appointed to the Board of the College of Technologists, 1500
Chitinase from *Streptomyces* sp. : Effect of Lytic Enzyme from *Bacillus circulans* and, on *Aspergillus oryzea* (Koki Horikoshi and Dr. Shigeji Iida), 186
Chittum, J. F. : Feedback Theory of Hydrogen Overvoltage, 589
Chivers, H. J. A., and Wells, H. W. : A New Ionospheric Phenomenon, 1178
Chloral Hydrate : Effect of, on Growth of Hair (Prof. J. Randolph Murray), 984
Chloramphenicol : Reduction in the Lethal Effects of Radiations on *Escherichia coli B* by Treatment with (Dr. N. E. Gillies and Tikvah Alper), 237
Chloramphenicol and the Survival of Airborne Bacteria (S. J. Webb), 1072
Chlorella : An Effect of Yeast Extract on the Growth of (P. J. Casselton), 1404
Chlorella vulgaris : Effect of Heavy Water on the Growth of (Janet R. Walker and P. J. Syrett), 1193
Chloride (Cobalt)–Water–Acetone : Existence of Two Liquid Phases in the System (Dr. J. N. Murrell, Dr. L. I. Katzin and B. L. Davies), 459
Chloride (Isosmotic Potassium) : Excitation of the Squid Axon Membrane in (Dr. John W. Moore), 265
Chloride (Neotetrazolium) : Reduction of, by Vitamin K_3 (T. F. Slater), 50
Chloride (Polyvinyl) : Enhancement of Radiation-induced Cross-linking of (Dr. S. H. Pinner), 1108
Chloride (Radioactive Ferric) : Effect of Dietary Phytate on Faecal Absorption of (Dr. Henry Foy, Athena Kondi and W. H. Austin), 691
Chloride (Sodium) : Adaptation of Marine Bacteria to Growth in Media lacking (Prof. D. B. Pratt and G. Waddell), 1208
Chloride (Sodium) Surfaces : Slip Sources on (Z. Morlin), 1319
Chloride Ion Contents and Protein Fractions in the Fluids of Chick Embryos : Sodium, Potassium, Calcium and (Dr. Aleksandra Smoczkiewiczowa), 1260
'Chloride-Secretory' Cells in the Gills of Teleosts (Gwyneth Parry, and F. G. T. Holliday and J. H. S. Blaxter), 1248
Chlorination of Proteins as a Method of Increasing their Opacity in the Electron Microscope (Dr. M. M. Coombs and Prof. J. F. Danielli), 1257
Chlorine : A Spectrophotometric Method for the Determination of (Zd. Spurny), 1390
Chlorins : Detection of Hydroxyl Groups in Porphyrins and (J. Barrett), 1185
Chlorophyll *in vivo* and *in vitro* : Isomerization of Poly-*cis*-carotenes by (Dr. H. Claes and T. O. M. Nakayama), 1053
Chlorophyll Formation in Albino Citrus Seedlings : Inducing (Dr. Faisal A. Minessy), 553
Chlorophyll *a* in some Corals and Marine Plants (Dr. Paul R. Burkholder, Lillian M. Burkholder and Juan A. Rivero), 1338
Chlorophyll *a* under Ultra-Violet Irradiation : Reduction of Menadione in Hexane by (Rudolph J. Marcus and Lloyd K. Moss), 990
Chlorophyll *b* : Absoprtion Spectrum and Decay Kinetics of the Metastable State of (Prof. Stig Claesson, Lars Lindqvist and Bertil Holmström), 661
Chloroplasts (Isolated) : Photochemical Reduction of Blue Tetrazolium by (John J. Taylor and Prof. Meyer Chessin), 626
Chlorothiazid in Diabetes Insipidus (Dr. J. D. Crawford and Dr. G. C. Kennedy), 891, 1368
Chlorpheniramine : Resolution of, and the Pharmacological Properties of its Isomers (R. T. Brittain, Dr. P. F. D'Arcy and Dr. J. H. Hunt), 734
Chlorpromazine : Free Radicals from (Dr. I. Gordon Fels and Marty Kaufman), 1392
  Role of Liver in Metabolism of (Dr. R. L. Young, J. J. Ross, jun., and Dr. A. R. Maass), 1396
Chmielowski, J., and Isaac, Peter C. G. : Gas–Chromatographic Observation of the Reduction of Carbon Dioxide to Methane during Anaerobic Digestion, 1120
Cholesterol-4-^{14}C : Persistence of, in the Central Nervous System (Dr. A. N. Davison and Martha Wajda), 1606
Cholesterol-level (Serum), of Rats : Influence of Dietary Cod-liver Oil and some Fractions of Cod-liver Oil on (A. P. de Groot and S. A. Reed), 1191
Choline and Inositol : Antagonism of (Dr. B. W. Agranoff and M. R. Spivey Fox), 1259
Cholinesterase of the Electric Eel : Stability of (J. F. Scaife), 541
Cholinesterase Types (Human Serum) : Differential Response of, to an Inhibitor in Potato (Dr. H. Harris and Mary Whittaker), 1808
Chondritic Meteorites : Natural Magnetic Moments of Two (Dr. F. D. Stacey and Dr. J. F. Lovering), 529
Chou Moellier (*Brassica oleracea* var.) : A Germination Inhibitor and Root-Growth Retarder in (A. G. Campbell), 1263
Choudhury, S. S., and others : Alicyclicity and Smoke Emission of Coal, 1613
Chown, Dr. Bruce, and others : A Further Example of the Kell Blood Group Phenotype K–, k–, Kp(a–b–), 1586
Christensen, Dr. L. Korsgaard : Thyroxine-releasing Effect of Salicylate and of 2,4-Dinitrophenol, 1189
Christian Ireland : Early (Máire and Liam de Paor), *review* by Joseph Raftery, 1704
Christie, M. : Parasitology (Parasitic Diseases of Domestic Animals), 1507
Christopherson, Prof. D. G. : On Being a Technologist, 1780
Chromaffin Cells : A New Type of, probably storing Dopamine (Bengt Falck, Prof. Nils-Åke Hillarp and Alf Torp), 267
Chromatograms (Column) : Adaptation of a Photometer for the Direct Recording of (Prof. M. Verzele), 604
Chromatograms (Paper) : Detection of Meprobamate on (H. S. Bedson and T. H. Farmer), 43
  Quantitative Estimation of Purines by the Visual Scanning of Photographs of (B. M. Johnstone and G. P. Briner), 681
Chromatograms (Salting-out Paper), of Antibiotics : New Types of (Dr. Joseph Úri), 1188
Chromatograph : Circular Gas (Dr. Roger S. Porter and Dr. Julian F. Johnson), 391
Chromatographic Analysis for Ricinine (Trevor Robinson and Elvin Fowell), 833
Chromatographic Behaviour of Human Albumin labelled with Iodine-131 (Dr. S. Cohen), 393
Chromatographic Method (A Two-Dimensional Paper), combining Ion-Exchange and Partition Techniques (C. S. Knight), 165
Chromatographic Patterns of Deoxyribonucleic Acid from various Tissues : Differences in (Nokubo Kondo and Syozo Osawa), 1602
Chromatographic Technique for Studying the Mechanism of Surface Catalysis (Kenzi Tamaru), 319
Chromatography : Detection and Estimation of Benzenoid Compounds by (P. Moss and A. J. Thomas), 1611
  Gas (Formation of a Special Group under the auspices of the Analytical Chemistry Section of the International Union of Pure and Applied Chemistry, to make recommendations for a standard terminology in), 722
Chromatography (Gas) : Analysis by, of a 'Pure' Sample with an 'Impure' Carrier (V. Willis), 1754
  Direct Examination of the Degradation of High Polymers by (Dr. R. S. Lehrle and Prof. J. C. Robb), 1671
  Effect of the Carrier Gas on the Sensitivity of a Thermal-conductivity Detector in (L. J. Schmauch and R. A. Dinerstein), 673 ; (Dr. N. H. Ray), 674
  Effect of the Carrier Gas on the Sensitivity of Thermal Conductivity Detectors in (Dr. B. A. Scott and Dr. A. G. Williamson), 1322
  Peak Dimensions in (C. H. Bosanquet), 252
  Separation of *m*-Xylene and *p*-Xylene by (D. H. Desty, A. Goldup and W. T. Swanton), 107
  Use of Katharometers in (Murray Eden, Arthur Karmen and John L. Stephenson), 1322
Chromatography (Gas–Liquid) : Nylon Capillary Columns for use in (R. P. W. Scott), 1753
Chromatography (Paper) : Conversion of Caffeic Acid to Esculetin during (Warren L. Butler and H. W. Siegelman), 1813
Chromatography (Rapid Quantitative Horizontal Paper), at an Elevated Temperature—Determination of Aspartic and Glutamic Acids (Henry R. Roberts and Michael G. Kolor), 460
Chromium–Iron and Chromium–Manganese Alloys : Low-temperature Specific Heats of Body-centred Cubic (C. T. Wei, C. H. Cheng and Prof. P. A. Beck), 315
Chromium–Manganese Alloys (Chromium–Iron and) : Low-temperature Specific Heats of Body-centred Cubic (C. T. Wei, C. H. Cheng and Prof. P. A. Beck), 315
Chromium Steel (12 per cent) : A New Silicide in a (H. Hughes), 1543
Chromosomal Aberrations : A New Physical Method of creating (Dr. John H. Heller and Dr. A. A. Teixeira-Pinto), 905
Chromosomal Reproduction : Effect of Colchicine on the Utilization of Thymidine labelled with Tritium during (L. F. La Cour and Dr. S. R. Pelc), 1455
Chromosome Changes (Structural) : Induction of, by Visible Light (Dr. B. A. Kihlman), 976
Chromosome Maps of *Saccharomyces* (Prof. Carl C. Lindegren, Gertrude Lindegren, Ernest E. Shult and Sharon Desborough), 800
Chromosome Number of the Potato Root Eelworm, *Heterodera rostochiensis* Wollenweber (J. Cotten), 128
Chromosome Numbers (Two New Basic), in the Musaceae (K. Shepherd), 1539
Chromosome Pairing in Intergeneric Hybrids with Wheat : Genetic Control of (Dr. Ralph Riley, Victor Chapman and Gordon Kimber), 1244
Chromosomes (Dividing) : Distribution of Newly Synthesized Deoxyribonucleic Acid in (Philip S. Woods and Marie U. Schairer), 303
Chromosomes (Lampbrush) : Some Effects of Colchicine on (A. P. Amarose), 975
Church, Brooks D., and Halvorson, Harlyn : Dependence of the Heat Resistance of Bacterial Endospores on their Dipicolinic Acid Content, 124
Churchill College, Cambridge : Sir John Cockcroft to become the first Master, 294
  Recognition as an approved foundation of the University of Cambridge, 349
Chymotrypsin : Asymmetric Hydrolysis of Diethyl Acetamidomalonate by (Prof. Saul G. Cohen and Lucille Altschul), 1678
Ciampi, Elgin (Ray, Carleton, and) : The Underwater Guide to Marine Life, *review* by Dr. D. P. Wilson, 852
Ciba Fellowship Trust : Award of Fellowships for 1959-1960, 1161

Ciba Foundation : Symposium on the Scope of Physical Anthropology and its Place in Academic Studies (edited by D. F. Roberts and J. S. Weiner), *review* by Dr. Kenneth Little, 70
  Colloquia on Ageing, Vol. 4, Water and Electrolyte Metabolism in relation to Age and Sex (edited by G. E. W. Wolstenholme and Maeve O'Connor), *review* by Prof. P. L. Krohn, 777
  Symposium on the Neurological Basis of Behaviour (edited by G. E. W. Wolstenholme and Cecilia M. O'Connor), (in commemoration of Sir Charles Sherrington, 1857-1952), *review* by Dr. P. B. Bradley, 954
  Report for 1958, 1717
Ciliary Activity by Negative Air Ions : An Enzymatic Basis for the Acceleration of (Prof. A. P. Krueger and Richard F. Smith), 1332
Ciphers in Organic Chemistry : Names and, *review* by Dr. E. H. Rodd, 960
Circuits (Printed) : The Technology of (Dr. Paul Eisler), *review* by J. C. Cluley, 1487
Circular Gas Chromatograph (Dr. Roger S. Porter and Dr. Julian F. Johnson), 391
Circulating Cells of Infectious Mononucleosis : Incorporation of Thymidine labelled with Tritium by (Dr. F. Gavosto, A. Pileri and G. Maraini), 1691
Circulation (Cerebral), and Metabolism in a Pyridoxine-dependent Child : Effects of Pyridoxine Withdrawal on (Dr. Louis Sokoloff, Dr. Niels A. Lassen, Dr. Guy M. McKhann, Dr. Donald B. Tower and Dr. Wayne Albers), 751
Circulation (Water), in the Black Sea : Microbiology and (A. E. Kriss), 437
Circulation (Water), in Oceans (V. G. Bogorov and E. M. Kreps), 437
Circulus Willisii of Atherosclerotic Individuals : Composition of Lipids isolated from the Aorta, Coronary Arteries and (Prof. C. J. F. Böttcher, F. P. Woodford, C. Ch. Ter Haar Romeny, E. Boelsma and C. M. Van Gent), 47
Cis-trans Isomerism of Thioindigo Dyes in the Solid State (Dr. G. S. Egerton), 389
Citron, K. M., and others : Immunological Aspects of Allergic Disorders (Allergic Hypersensitivity in Man to *Aspergillus fumigatus*), 297
Citrus Fruit : Isolation of *l*-Quinic Acid in (Dr. S. V. Ting and Dr. E. J. Deszyck), 1404
Citrus Ovules : Morphogenetic Response of, to Growth Adjuvants in Culture (N. S. Ranga Swamy), 735
Citrus Seedlings (Albino) : Inducing Chlorophyll Formation in (Dr. Faisal A. Minessy), 553
Citterio, C. (Mascitelli-Coriandoli, E., and) : Effects of Vanadium upon Liver Coenzyme *A* in Rats, 1527
City Literary Institute, London : Science Lectures (Tools of Scientific Discovery—a Review for the Layman and Non-Specialist), 18
City and Guilds of London Institute and the Institute of Science Technology : Rationalization of examinations and qualifications for science laboratory technicians, 863
Civic Trust : Work of the, 1092
Cladocera : Carotenoid Pigment in *Spirobacillus cienkowskii* Metchnikoff, a Pathogen of (J. Green), 56
Claes, Dr. H., and Nakayama, T. O. M. : Isomerization of Poly-*cis*-carotenes by Chlorophyll *in vivo* and *in vitro*, 1053
Claesson, Prof. Stig, and others : Absorption Spectrum and Decay Kinetics of the Metastable State of Chlorophyll *b*, 661
  Action of Ultra-violet Light on Skin—Effect of the Histamine Liberator 48/80 and Methotrimeprazine, 1451
Clam : Effect of Brain Ganglioside on the Heart of the (Dr. Samuel Bogoch and Elenore S. Bogoch), 53
Clancy, M. J. (Turvey, Dr. J. R., and) : Some Methods for the Purification of Sugar Sulphates, 537
Clapeyron's Equation : Validity of, for Phase Equilibria involving Clathrates (Dr. J. H. van der Waals and Dr. J. C. Platteeuw), 462 ; (Prof. R. M. Barrer), 463
Clapham, Prof. A. R. : Elected a Fellow of the Royal Society, 860
Clark, Dr. A. M. : Mutagenic Activity of the Alkaloid Heliotrine in *Drosophila*, 731
Clark, Comdr. E. Bidder, and Clark, Dr. G. Kitson : The Art of Lecturing, enlarged edition, 1623
Clark, E. R. : Interaction between Organic Hydroxy Acids and Germanic Acid in Aqueous Solution, 536
Clark, Francis E., and others : Responses of Seedlings to Extracts of Soybean Nodules bearing Selected Strains of *Rhizobium japonicum*, 308
Clark, Dr. G. A. : Administrative Medicine, *review*, 639
Clark, Dr. G. Kitson, and Clark, Comdr. E. Bidder : The Art of Lecturing, enlarged edition, 1623
Clark, J. E. (Heath, Prof. O. V. S., and) : Metal-Chelating Properties of Plant-Growth Substances, 1167
Clark, M. E. (Clark, Dr. R. B., and) : Role of the Supra-oesophageal Ganglion during the Early Stages of Caudal Regeneration in some Errant Polychaetes, 1834
Clark, Dr. R. B., and Clark, M. E. : Role of the Supra-oesophageal Ganglion during the Early Stages of Caudal Regeneration in some Errant Polychaetes, 1834
Clark, Sir Wilfrid le Gros: Bronze bust in the new building of the Department of Human Anatomy, Oxford, 1573
Clarke, Dr. C. A. : Natural Selection in Man, 160
Clarke, R. H. : Antarctic Meteorology, 1503
Clarkson, J. K. (Deutsch, Dr. J. A., and) : Nature of the Vibrato and the Control Loop in Singing, 167
Class of Biologically Active Substances : 'Pheromones', a New Term for a (Dr. P. Karlson and Prof. M. Lüscher), 55
Class (Social), and Mental Illness (Prof. August B. Hollingsworth and Prof. Frederick C. Redlich), *review* by Dr. Clifford Allen, 354
Classical Association (London Branch), and others : Debate on the motion 'That the Education of our Future Rulers should be primarily in the Sciences rather than in the Humanities', 510, 1235
Classification of the Digenetic Trematodes, *review* by Dr. Ben Dawes, 957
Classification of Glume Colour in Nigerian Cultivated Sorghums : A Chemical Basis for the (W. R. Stanton, T. B. Miller and D. L. Curtis), 807
Classification of the Tea Plant : Nomenclature and (Dr. W. Wight), 1726
Classified Bibliography of Gerontology and Geriatrics, Supplement 1, 1949-1955 (Dr. Nathan W. Shock), *review* by Prof. P. L. Krohn, 777
Clathrates : Validity of Clapeyron's Equation for Phase Equilibria involving (Dr. J. H. van der Waals and Dr. J. C. Platteeuw), 462 ; (Prof. R. M. Barrer), 463
Clausen, Prof. Jens C. : Elected a member of the United States National Academy of Sciences, 1575
Claxton, G. : Physical and Azeotropic Data—Hydrocarbons and Sulphur Compounds boiling below 200°C., *review* by Dr. B. A. Rose, 709
Clay Minerals and Biological Fibres (X-Ray Analysis Group of the Institute of Physics Conference on), 1024
Clay Minerals and Industry (Clay Minerals Group of the Mineralogical Society Meeting on), 1024
Clay–Water Systems : Swelling of (L. A. G. Aylmore and Dr. J. P. Quirk), 1752
Clays : Latent Interparticle Forces in (R. H. G. Parry), 538
Clayton, C. G., and others : Conductivity induced by Radiation in Polycrystalline Cadmium Sulphide and Polyethylene, 1112
Clayton (James) Prize for 1958 of the Institution of Mechanical Engineers awarded jointly to William Munger Heynes and Sir F. Ewart Smith, 865
Clayton, Y. M., and others : Immunological Aspects of Allergic Disorders (Allergic Hypersensitivity in Man to *Aspergillus fumigatus*), 297
Clearance-rates (Iodine-131), as an Indication of the Blood Supply of Bone (Dr. P. G. Laing and Dr. Albert B. Ferguson, jun.), 1595
Cleavage Faces (Calcite) : Etch Pits on (Dr. H. Watts), 314; (R. C. Stanley), 1548
Cleavage Fracture (Ductile), of Molybdenum (A. A. Johnson and B. J. Shaw), 1542
Cleaver, A. V. : Hydrogen Liquefaction and Associated Techniques (Liquid Hydrogen as a Rocket Fuel), 1505
Clegg, John : The True Book about Insects, *review* by B. D. Moreton, 709
Clematis Cuttings : Effect of Boron on the Rooting of (Dr. C. J. Weiser), 559
Clemedson, Carl-Johan, and others : Bone and Radiostrontium, *review* by J. Vennart, 965
Clerk in Industry : The, *review*, 494
Clifton, Charles E. (edited by, in association with Raffel, Sidney, and Starr, Prof. Mortimer P.) : Annual Review of Microbiology, Vol. 12, *review*, 1219
Climate of New Zealand (Prof. B. J. Garnier), *review* by Prof. Gordon Manley, 421
Climatological Wind Tunnel (Dr. P. E. Weatherley and H. D. Barrs), 94
Climatology : Geographical, *review* by Prof. Gordon Manley, 421
Clinical Chemistry : Advances in (edited by Dr. Harry Sobotka and Dr. C. P. Stewart), Vol. 1, *review* by Prof. J. N. Davidson, 5
Clinical Enzymology (edited by Dr. Gustav J. Martin), *review* by Prof. F. G. Young, 1151
Clinical Haematology in Medical Practice (Dr. G. C. de Gruchy), *review* by Dr. R. Biggs, 1151
Clinical Research (Basic and), of the New Antibiotic, Kanamycin (Maxwell Finland, and 93 other authors), 1570
Clinical and Experimental Cancer Research, *review* by Dr. L. Foulds, 955
Clipping the Coat : Effect of, on the Thermoregulatory Reactions of Dairy Heifers (H. Berman and H. H. Kibler), 606
Clock' ('Internal), in *Arthrenus verbasci* (L.) (Col., Dermestidae) : Control of Diapause by an (G. M. Blake), 126
Clotting : Appearance of a Phosphorus Compound in Platelet-rich Plasma on (Dr. G. V. R. Born and Dr. M. P. Esnouf), 478
Cloud (Large Magellanic) : Planetary Nebulae in the (E. M. Lindsay), 453
Cloud Droplets : Detachment of Conidia by (Dr. R. R. Davies), 1695
Clough Memorial Research Fund of the Edinburgh Geological Society : Grants for geological research in Scotland and the north of England, 582
Cluley, J. C. : Printed Circuits, *review*, 1487
Coal : Alicyclicity and Smoke Emission of (B. K. Mazumdar, S. S. Choudhury and A. Lahiri), 1613
  The Nature of (Central Fuel Research Institute, India, Symposium on), 86, 1438
  Chemicals, Oil and Gas from (Ministry of Power to set up a Committee on), 1162
  Potentiometric Titration of, in a Non-Aqueous Medium (W. J. S. Pringle), 815
Coal Utilization Research Association, British : Open Days, 1024, 1786
Coal, Electricity and Gas Industries : Investment in the, 1650
Coales, J. F. : Education of Instrument Technologists and Control Engineers (Presidential Address to the Society of Instrument Technology), 1433
Coals : Alicyclic Structures in (S. Ergun and V. H. Tiensuu), 1668
Coast (Atlantic), of France: *Balanus tulipiformis* Ellis on the (B. S. Kisch), 341
Coast (Chilean) : Relationship between the Hake Fishery and a Southerly Sub-surface Return Flow below the Peru Current off the (Dr. Wilhelm Brandhorst), 1832
Coast (Madras) : Metacercaria (Allocreadioidea) in the Planktonic Ctenophore, *Pleurobrachia globosa* Moser 1903, from the (Mrs. Sita Anantaraman), 1407
Coat : Effect of Clipping the, on the Thermoregulatory Reactions of Dairy Heifers (H. Berman and H. H. Kibler), 606
Coat Color in Dogs : The Inheritance of (Dr. Clarence C. Little), *review* by Dr. Alex Comfort, 5
Coates, G. E., and others : Co-ordination Chemistry (Alkyl and Aryl Palladium Compounds), 1785
Coatings (Resin-bonded), of Polytetrafluoroethylene (Acheson Colloid, Ltd.), 1501
Coats, D. A., and others : Lithium Retention in Ascites Tumour Mice, 1128
Coats (Peter) Scholarship (Textile Institute), 933
Cobalt in Dietary Necrotic Liver Degeneration : Ineffectiveness of Molybdenum, Osmium and (Dr. Klaus Schwarz, Edward E. Roginski and Calvin M. Foltz), 472
Cobalt Chloride–Water–Acetone : Existence of Two Liquid Phases in the System (Dr. J. N. Murrell, Dr. L. I. Katzin and B. L. Davies), 459
Cockburn, Dr. Alexander M. : *Obituary* by Prof. F. H. Stewart, 1017
Cockcroft, Sir John : Honorary degree of doctor of technical science conferred on, by the Technical University of Delft, 154
  To become the first Master of Churchill College, Cambridge, 294
Cockrem, F. : Selection for Relationships Opposite to those predicted by the Genetic Correlation between Two Traits in the House Mouse (*Mus musculus*), 342
  Effect of a Sympathomimetic Agent (Methoxamine Hydrochloride) on Growth of Hair in the House Mouse (*Mus musculus*), 614
Cod : The Bear Island—Migrations and Movements (G. C. Trout), 1100

Cod-liver Oil (Dietary), and some Fractions of Cod-liver Oil : Influence of, on Serum Cholesterol-level of Rats (A. P. de Groot and S. A. Reed), 1191
Cod Myosin : Aggregation of, during Frozen Storage (J. J. Connell), 664
Coe, E. L., and others : Energy Compensation in the Crabtree Effect with Ehrlich Ascites Carcinoma Cells, 1471
Coed Dolgarrog Nature Reserve (Nature Conservancy), 1649
Coed Gorswen Nature Reserve (Nature Conservancy), 1650
Coefficient (Townend's First Ionization), in Pure Nitrogen (Dr. A. E. D. Heylen), 1545
Coelacanth : Anatomy of a, *review* by Dr. E. Trewavas, 566
Coelenterata (Precambrian), from Australia, Africa and England (Dr. M. F. Glaessner), 1472
Coenzyme A (Liver), in Rats : Effects of Vanadium upon (E. Mascitelli-Coriandoli and C. Citterio), 1527
Co-existence of the Embryonic (Third Normal) Haemoglobin Fraction with Erythroblastosis in the Blood of Two Full-term New-born Babies with Multiple Malformations (Prof. I. Halbrecht, Ch. Klibanski and F. Bar Ilan), 327
Coffees (Ethiopian) : Preliminary Information on the Genetics of (Dr. Alcides Carvalho), 906
Coffield, T. H., and co-workers : Co-ordination Chemistry (Carbon Monoxide Exchange Studies), 1785
Cohen of Birkenhead, Rt. Hon. Lord : Sherrington—Physiologist, Philosopher and Poet, *review* by Prof. K. J. Franklin, 209
Cohen, Dr. A. (Cohen, Dr. L., and) : Radiosensitivity as a Function of Antigenic Equivocation, 692
Cohen, Dr. Alvin J. : Origin of Libyan Desert Silica-Glass, 1548
Cohen, Dr. Alan S., and Calkins, Dr. Evan : Electron Microscopic Observations on a Fibrous Component in Amyloid of Diverse Origins, 1202
Cohen, Prof. John : Behavior and Psychological Man, *review*, 781
Cohen, Prof. John, and Hansel, C. E. M. : Preferences for Different Combinations of Chance and Skill in Gambling, 841
Cohen, Dr. L., and Cohen, Dr. A. : Radiosensitivity as a Function of Antigenic Equivocation, 692
Cohen, Dr. Melvin : The Ear under Water (Anatomy of the Statocyst of the Lobster, *Homarus americanus*), 1787
Cohen, Dr. S. : Chromatographic Behaviour of Human Albumin labelled with Iodine-131, 393
Cohen, Prof. Saul G., and Altschul, Lucille : Asymmetric Hydrolysis of Diethyl Acetaminomalonate by Chymotrypsin, 1678
Cohesive Energy Density of Polystyrene (Dr. J. H. S. Green), 818
Cohn, Dr. N. S., and Merz, Dr. T. : A Technique for the Sterile Culture of Roots, 412
Coitus (Triple), in the Mealy Bug, *Planococcus citri* (Risso), (Walter A. Nelson-Rees), 479
Coker, Prof. E. G., and Filon, Prof. L. N. G. : A Treatise on Photo-Elasticity, second edition, revised by H. T. Jessop, *review* by E. K. Frankl, 1010
Colchicine : Effect of, on the Utilization of Thymidine labelled with Tritium during Chromosomal Reproduction (L. F. La Cour and Dr. S. R. Pelc), 1455
  Inhibitory Effect of, upon the Transplantable Fibroma of the Skin in the Newt *Triturus taeniatus* (Prof. A. Stolk), 555
  Some Effects of, on Lampbrush Chromosomes (A. P. Amarose), 975
Cold Spring Harbor Symposia on Quantitative Biology : Vol. 24, Genetics and 20th Century Mendelism, 934
  Vol. 22, Population Studies—Animal Ecology and Demography, *review* by Dr. A. Milne, 1220
Cole, Eric K. : Elected an honorary member of the British Institution of Radio Engineers, 582
Cole, Prof. F. J. : *Obituary* by Prof. Chas. H. O'Donoghue, 788
Cole, Dr. H. A. : Appointed director of fisheries research in the Ministry of Agriculture, Fisheries and Food, 1567 ; work of, 1567
Cole, K. D. : Low-Energy Corpuscular Radiation at High Latitudes, 738
Coleoptile Tissues : Relationship between Auxins and Nucleic Acid Synthesis in (B. B. Biswas and S. P. Sen), 1824
Collagen : Occurrence of 'Ester-like' Linkages in (Paul M. Gallop, Prof. Sam Seifter and Edward Meilman), 1659
Collagen in the Perilemma of Insect Nerve (David S. Smith and Prof. V. B. Wigglesworth), 127
Collagen Content of Normal Connective Tissue, of Tissue surrounding a Tumour and of Growing Rat Sarcoma (Maria Grabowska), 1186
Collagen Structure : Possible Role of Water in (R. D. B. Fraser and T. P. Macrae), 179
Collard, Prof. Patrick, and Levi, Simon : A Two-stage Fermentation of Cassava, 620
Collective Motion in Physics : Problems of (Physical Society Conference on), 866
College of Technologists : Creation of the, 1500
  Appointments to the Board, 1500
College Biology Courses on Television, 649
College (The American), and the Educated Life (Dr. Douglas M. Knight), 1769
Colleges and Universities : Scientific Research and Development in—Expenditure and Manpower, 1953-54 (National Science Foundation), 1716
Collier, Prof. H. Bruce (Tsen, Dr. Cho Ching, and) : Selenite as a Relatively Weak Inhibitor of some Sulphydryl Enzymes, 1327
Collier, Dr. H. O. J. : Chemotherapy of Parasitic Diseases, 1030
  Appointed to the Board of the College of Technologists, 1500
Collier, Dr. H. O. J., and others : A New Short-Acting Thiobarbiturate, 1443, *erratum*, 1571
Colloid Goitre (Experimental), produced by Thiouracil (Dr. R. H. Follis, jun.), 1817
Colloid Osmotic Pressure of Rheumatoid Synovial Fluid (Paave Mäkinen and Eino Kulonen), 475
Colloid Science : Electrical Double Layer in (Colloid and Biophysics Committee of the Faraday Society Discussion on), 78
Colombo Plan for Co-operative Economic Development in South and South-East Asia : Seventh Annual Report of the Consultative Committee (Seattle, 1958), 1099
Colon ('Isolated') : Enzyme Activity in the (Dr. B. F. Martin), 1464
Colonial Agricultural, Animal Health and Forestry Research, Committee for : Thirteenth Annual Report (1957-58), 703
Colonial Development and Welfare Bill : Second reading of the, 793
Colonial Economic Research Committee : Eleventh Annual Report (1957-58), 703
Colonial Fisheries Advisory Committee : Annual Report (1957-58), 703
Colonial Geology and Mineral Resources renamed *Overseas Geology and Mineral Resources* (Overseas Geological Surveys), 581
Colonial Medical Research Committee : Thirteenth Annual Report (1957-58), 703
Colonial Pesticides Research Committee : Eleventh Annual Report (1957-58), 703
Colonial Products Council : Fifth Annual Report (1957-58), 703
Colonial Research 1957-58—Reports of the Colonial Research Council ; Committee for Colonial Agricultural, Animal Health and Forestry Research ; Colonial Economic Research Committee ; Colonial Fisheries Advisory Committee ; Colonial Medical Research Committee ; Colonial Pesticides Research Committee ; Colonial Social Science Research Council ; Tsetse Fly and Trypanosomiasis Committee, Director of the Anti-Locust Research Centre ; and Research Matters not covered by the above Reports of the Specialist Advisory Bodies, 703
Colonial Research Council : Annual Report of the, 703
Colonial Road Research Committee : Third Annual Report (1957-58), 703
Colonial Social Science Research Council : Fourteenth Annual Report (1957-58), 703
Color (Coat), in Dogs : The Inheritance of (Dr. Clarence C. Little), *review* by Dr. Alex Comfort, 5
Colorimetric Analysis (Noel L. Allport and Dr. J. W. Keyser), Vol. 1, Determinations of Clinical and Biochemical Significance, second edition, *review* by Dr. N. R. Lawrie, 207
Colorimetry in Biochemistry, *review* by Dr. N. R. Lawrie, 207
Colour in Frogs : Serotonin and Change of (Dr. K. G. Davey), 1271
Colour (Autumn), and Leaf-fall of Deciduous Woody Plants : Effect of Gibberellic Acid on Development of (Dr. P. W. Brian, J. H. P. Petty and P. T. Richmond), 58
Colour (Glume), in Nigerian Cultivated Sorghums : A Chemical Basis for the Classification of (W. R. Stanton, T. B. Miller and D. L. Curtis), 807
Colour-blindness in Klinefelter's Syndrome (Prof. Curt Stern), 1452
Colour Centres in Silica : Synthesis of, and their Thermoluminescence (J. R. Hensler), 672, *erratum*, 1434
Colour Reaction for Thiosulphinates (John F. Carson and Francis F. Wong), 1673
Colour Vision : Mixed Pigments in (Dr. R. W. G. Hunt), 1601
Colour Vision Phenomenon of a New Class (Dr. William A. Shurcliff), 202
Colours of Dogs, *review* by Dr. Alex Comfort, 5
Colson, P. (Gillet, Prof. A., and) : The Nature of Coal (Petroleum and Anthracite from Cellulose), 1438
Colston Research Society : Observation and Interpretation—Proceedings of the Ninth Symposium held at the University of Bristol, 1957 (edited by Prof. S. Körner in collaboration with Prof. M. H. L. Pryce), *review* by Dr. E. F. Caldin, 1010
Colton, Dr. Ervin, and St. Cyr, Lewis: Solution of Iodine in Phosphorus (III) *Iso*cyanate, 1042
Colton, R., and others : Lowest Oxidation States of Technetium and Rhenium, 1755
Column Chromatograms : Adaptation of a Photometer for the Direct Recording of (Prof. M. Verzele), 604
Colvin, Dr. J. Ross : Synthesis of Cellulose in Ethanol-Extracts of *Acetobacter xylinum*, 1135
Coma Cluster of Galaxies : A High-Resolution Survey of the, at 408 Mc./s. (Dr. M. I. Large, D. S. Mathewson and C. G. T. Haslam), 1663
Combinations (Antibiotic) : Application of Logarithms to the Base 2 in the Use of Exponential Dilution Series for the Study of (H. J. Oskam and A. Koelman), 840
Combinations (Different), of Chance and Skill in Gambling : Preferences for (Prof. John Cohen and C. E. M. Hansel), 841
Combinatorial Analysis : An Introduction to (John Riordan), *review* by Dr. L. S. Goddard, 970
Combining Sites of an Antibody : Effect of Hydrolysis by Papain on the (Dr. A. Nisonoff and D. L. Woernley), 1325
Combustibles et de l'Energie, Institut Français des : Gold Medals presented to Dr. D. T. A. Townend, Prof. W. H. McAdams, G. Darrieus, Prof. G. Ribaud, Dr. F. Münzinger and F. Squassi, 151
Comfort, Dr. Alex : The Colours of Dogs, *review*, 5
Comforts : Atomic, *review* by Prof. G. O. Jones, 1077
Comité Européen de Zoologie Agricole and the Agricultural University, Wageningen (under the auspices of the) : Proceedings of a Symposium on Insect and Food-plant (Wageningen, 1957), *review* by Dr. C. J. Banks, 1767
Comline, Dr. R. S., and others : Changes in the Secretion of 20α-Hydroxypregn-4-en-3-one by the Adrenal Gland of Young Calves, 467
Comments on the Job (Dr. Isabel Blain), 372
Commercial Basis : Nuclear Reactors on a, 436
Commercial Manufacture of Nuclear Fuel Elements, 1232
Common, Prof. R. H., and Mok, Chi-Ching : Phosvitin in the Serum of the Hen, 1811
Common Frog : An Albino Specimen of the (G. E. Williams), 1408
Common Sense and Nuclear Warfare (Bertrand Russell), 1351
Common Shrew (*Sorex araneus* L.) : Seasonal Changes in the Brain-case of the (Peter Crowcroft and Jean M. Ingles), 907
Commons, House of : Debate on Government Aid to Science in Britain, 156
  Debate on Safety and the Nuclear Power Industry, 292
  Second reading of the Colonial Development and Welfare Bill, 793
  Debate on the National Parks (Amendment) Bill, 917
  Second reading of the Transport (Borrowing Powers) Bill, 938
  Debate on Education, 1145
  Debate on Space Research, 1302
  Debate on Fuel and Power Policy, 1650
Commonwealth : General Trends in Science Teaching in the Universities of the (Science Masters' Association Discussion on), 1571
  Scientific Co-operation in the, 775
Commonwealth (British) : Scientific Co-operation within the (H.R.H. the Duke of Edinburgh), 425
Commonwealth (British), Association of Universities of the : Report of the Executive Council for 1957-58, 1717
  Report of the Proceedings of the 1958 Home Universities Conference, 1764
Commonwealth Advisory Committee on Defence Science—Meeting in Australia (Sir Leslie Martin), 1165

Commonwealth Bursaries Scheme : Fifth Annual Report on the (Royal Society and Nuffield Foundation), 1304
Commonwealth Fund : Award of Harkness Fellowships for 1959, 1093
Commonwealth Scientific and Industrial Research Organization (Australia) : Ninth Annual Report (1956-57), 155
  Chemical Research Laboratories, 228
  Appointment of Dr. I. W. Wark as the first director of the Chemical Research Laboratories, 228
  Appointment of Dr. A. L. G. Rees as chief of the new Division of Chemical Physics, 228
  Appointment of Dr. K. L. Sutherland as chief of the new Division of Physical Chemistry, 228
  Rural Research, 228
  Annual Report for 1957-58 of the Division of Electrotechnology, 1781
Commonwealth Students in Britain : Funds for, 793
Communication in the Modern World (Granada Lectures of the British Association for the Advancement of Science), 293
Communication Principles at the Bell Telephone Laboratories, 648
Communications and Electronics Buyers' Guide, Who's Who and Reference Book, 1958-59 edition (edited by C. C. Gee, with the assistance of D. W. Dwyer), *review* by Prof. D. G. Tucker, 354
Comparative Anatomy (Zoology and), at Dublin, 1716
Comparative Sensitivity to Radiation of Seeds from a Wild Plant grown on Uraniferous and Non-Uraniferous Soils (Dr. D. J. Mewissen, J. Damblon and Prof. Z. M. Bacq), 1449
Comparison of the Formation of the Complex, Sensitized Erythrocyte-Complement ($EAC'_{1, 4, 2}$) in Haemolytic Systems differing in their Haemolysin and Complement-fixing Activities (Dr. Harold S. Goodman), 331
Comparison of Normal Adult Human Haemoglobin with Haemoglobin I by 'Fingerprinting' (Constituents of Human Haemoglobin), (Makio Murayama and Dr. V. M. Ingram), 1798
Compensation (Energy), in the Crabtree Effect with Ehrlich Ascites Carcinoma Cells (K. H. Ibsen, E. L. Coe and Dr. R. W. McKee), 1471
Complement Fixation with Tissue Culture and Liver Antigens of Mouse Hepatitis (Dr. Theodore J. Starr and Dr. Morris Pollard), 1690
Complement-fixing Activities : Comparison of the Formation of the Complex, Sensitized Erythrocyte-Complement ($EAC'_{1, 4, 2}$) in Haemolytic Systems differing in their Haemolysin and (Dr. Harold S. Goodman), 331
Complex in the *α*-Globulin Fraction in Human Serum : Prealbumin as a (Dr. J. R. Tata), 877
Complex, Sensitized Erythrocyte-Complement ($EAC'_{1, 4, 2}$) : Comparison of the Formation of the, in Haemolytic Systems differing in their Haemolysin and Complement-fixing Activities (Dr. Harold S. Goodman), 331
Complex (Blue–Snow Goose) : Assortative Mating and Reciprocal Difference in the (Dr. F. G. Cooch and Dr. J. A. Beardmore), 1833
Complex (Iron-*bis*-Indigo): Model Oxygen-carrying Compounds and the (L. F. Larkworthy and Prof. R. S. Nyholm), 1377
Complexes : Copper–Cellulose (Dr. D. S. Belford, C. D. Cook, E. H. Nevard and Prof. R. D. Preston), 988
  Methanol-soluble Carbohydrate (Ernest H. Freund and Kelvin Domovs), 1526
  β-Type Interlamellar Sorption (F. Aragon, J. Cano Ruiz and Dr. D. M. C. MacEwan), 740
Complexes with *Cyclo*hexylphosphine : Tetra-co-ordination of Nickel (II)—some (Dr. Aldo Turco, Dr. Vladimiro Scatturin and Dr. Giovanni Giacometti), 601
Complexes (Ferrous and Ferric), with Pyridine 2-Aldoxime (Dr. G. I. H. Hanania and Dr. D. H. Irvine), 40
Complexes (Histidine—Cu (II)) : Multiplicity of (R. Leberman and Dr. B. R. Rabin), 746
Complexes (Pentacyanocobaltate (III)) : Polarography of (Nobufumi Maki, Junnosuke Fujita and Ryutaro Tsuchida), 458
Component (Fibrous), in Amyloid of Diverse Origins : Electron Microscopic Observations on a (Dr. Alan S. Cohen and Dr. Evan Calkins), 1202
Components of Bacterial Cytoplasm : Effect of Drugs upon (Dr. S. Dagley and J. Sykes), 1608
Components (Normal), of Guinea Pig Serum which may cause Antigens to show an Apparent Anti-complementary Effect (M. M. H. Sewell), 1062
Components (Small), in Red Cell Haemolysates : Demonstration of, by Starch-gel Electrophoresis (Dr. Phaedon Fessas and N. Mastrokalos), 1261
Composition of the Configurational Stability of Deoxyribonucleic Acids : Dependence on (Heterogeneity in Deoxyribonucleic Acids, I), (Dr. Julius Marmur and Prof. Paul Doty), 1427
Composition of Lipids isolated from the Aorta, Coronary Arteries and Circulus Willisii of Atherosclerotic Individuals (Prof. C. J. F. Böttcher, F. P. Woodford, C. Ch. Ter Haar Romeny, E. Boelsma and C. M. Van Gent), 47
Composition (Amino-Acid), of the Proteins of Barley Leaves in relation to the Mineral Nutrition and Age of Plants (Dr. B. P. Pleshkov and Dr. L. Fowden), 1445
Composition (Cell-Wall), of *Leptotrichia* spp. (Dr. G. H. G. Davis and A. C. Baird-Parker), 1206
Composition (Chemical), of Tektites (Dr. Brian Mason), 254 ; (Prof. Harold C. Urey), 1114
Composition (Isotopic), of Boron and its Atomic Weight (W. J. Lehmann and I. Shapiro), 1324
Composition (Isotopic), of Lead from British Mineral Deposits (S. Moorbath), 595
Compound, I_2OH^- : A New Iodine (Dr. J. Sigalla), 178
Compound (An Iodine), associated with Albumin in the Plasma of Thyrotoxic Patients (Christina Cameron and K. Fletcher), 116
Compound (Phosphorus), in Platelet-rich Plasma on Clotting : Appearance of a (Dr. G. V. R. Born and Dr. M. P. Esnouf), 478
Compound (Second Yellow), from *Drosophila melanogaster* : Characterization of a (Dr. H. S. Forrest, Dolph Hatfield and Dr. C. Van Baalen), 1269
Compound Formation : Electrode Potentials and, in the Palladium–Platinum–Hydrogen System (A. W. Carson, Dr. T. B. Flanagan and Dr. F. A. Lewis), 39, 510
Compounding Ingredients for Rubber : British (compiled by Brian J. Wilson), *review* by Dr. W. J. S. Naunton, 779
Compounds : Aliphatic Fluorine (A. M. Lovelace, Douglas A. Rausch and William Postelnek), *review* by Prof. R. N. Haszeldine, 139
  Effect of Norleucine and related, on Growth of the White Rat (M. Rechcigl, jun., H. H. Williams and J. K. Loosli), 1519
  Inhibition of Sensitiveness to Nicotine of Rabbit Aorta by Reserpine, Hexamethonium, Ethyl Flavone-7-Oxyacetate and other (Dr. I. Setnikar and M. Ravasi), 898
Compounds (Benzenoid) : Detection and Estimation of, by Chromatography (P. Moss and A. J. Thomas), 1611
Compounds (C_2-) : Biosynthesis of Cell Constituents from—Formation of Malate from Glycollate by *Pseudomonas ovalis* Chester (Dr. H. L. Kornberg and A. M. Gotto), 1791 ; Metabolism of Glycine by a Pseudomonad (A. G. Callely and Dr. S. Dagley), 1793 ; Formation of Glycerate from Oxalate by *Pseudomonas oxalaticus* (OX1) grown in Oxalate (J. R. Quayle and Dr. D. B. Keech), 1794
Compounds (Crystal), of Graphite : Metallic Conduction in the (Prof. A. R. Ubbelohde, Dr. L. C. F. Blackman and J. F. Mathews), 454
Compounds (Enclathrated) : Molecular Motion of, as studied by Nuclear Magnetic Resonance (Dr. D. F. R. Gilson and Prof. C. A. McDowell), 1183
Compounds (Guanidinium), with Ninhydrin : Green Fluorescence of (Dr. Rex B. Conn, jun., and Dr. Richard B. Davis), 1053
Compounds (Metal Chelate), of *β*-Diketones : Metal–Oxygen Stretching Frequencies in the (Kazuo Nakamoto, Paul J. McCarthy and Arthur E. Martell), 459
Compounds (Model Oxygen-carrying), and the Iron-*bis*-Indigo Complex (L. F. Larkworthy and Prof. R. S. Nyholm), 1377
Compounds (Sulphur) : Inactivation of Organo-Mercurial Fungicides in Groundwood Pulp made from Logs stored in Salt Water and the Possible Role of (B. H. Browning, P, Russell, Dr. S. Kingsnorth and R. J. Peerless), 1346
Compounds (Sulphur), boiling below 200°C. : Physical and Azeotropic Data—Hydrocarbons and (G. Claxton), *review* by Dr. B. A. Rose, 709
Compounds (Transition Metal Co-ordination) : Explosion of (Seward E. Beacom), 38
Compounds (Trichloracetic Acid-insoluble Phosphate), in Cartilage (R. G. Whitehead and Dr. S. M. Weidmann), 876
Computation in Process Development and Plant Design : Instrumentation and (Institution of Chemical Engineers, the Society of Instrument Technology and the British Computer Society Joint Symposium on), 652
Computation and Control : Handbook of Automation, (edited by Eugene M. Grabbe, Simon Ramo and Dean E. Wooldridge), Vol. I, Control Fundamentals, *review* by P. H. Hammond, 1556
Computational Methods : Scholarships in Mathematics for Courses in Statistics and (London School of Economics and Political Science), 85
Computer : Braille Translation by, 1233
Computer and the Brain (Dr. John von Neumann), *review* by A. M. Armstrong, 350
Computer Society, British, and others : Joint Symposium on Instrumentation and Computation in Process Development and Plant Design, 652
Computer (Business) Synposium : Electronic Computer Exhibition and, 11
Computer (Electronic) Exhibition and Business Computer Symposium, 11
Computer (Electronic Digital) : The Preparation of Programs for an (Dr. Maurice V. Wilkes, Dr. David J. Wheeler and Dr. Stanley Gill), second edition, *review* by E. L. Albasiny, 969
Computers (Digital) : Automatic Programming of (Brighton Technical College Residential Working Conference on), 438, 1779
Computers (Electronic), in the Service of Business (W. L. C. Garrett), 11
Computers (Electronic Digital), and their Industrial Applications (Conference at the Birmingham College of Technology), 154
Computing Engine (The Automatic), at the National Physical Laboratory (J. H. Wilkinson and D. W. Davies), 22
Conant, Roger : A Field Guide to Reptiles and Amphibians of the United States and Canada East of the 100th Meridian, *review* by A. G. C. Grandison, 958
Concentration of Ammonium Sulphate Solutions : A Rapid Method for determining the (Dr. John A. Whitaker and Dr. Robert Hughes), 603
Concentration of Fluids containing Protein : A Simple Method for the (Dr. J. Kohn), 1055
Concentration (Salt), and Fibrinolytic Activity (Dr. Monamy Buckell and Margaret Truscott), 1268
Concentrations (Drug), in Biological Fluids : Direct Determination of, by Polarography (Dr. P. O. Kane), 1674
Concentrations (Low), of Alcohols : Effect of, on the Interfacial Tension between Water and Hydrocarbons (F. Franks and Dr. D. J. G. Ives), 316
Concept of Motivation (Dr. R. S. Peters), *review* by Prof. L. S. Hearnshaw, 567
Concept (Genetic), for the Origin of Cancer : Papers presented at the Conference on (Annals of the New York Academy of Sciences, Vol. 71), 1234
Conception of Nature : The Physicist's (Prof. Werner Heisenberg), *review* by Prof. W. H. McCrea, 1281
Concepts of Nuclear Physics, *review* by Prof. B. H. Flowers, 492
Conchie, F., and others : Glycosidases in some Farm Animals, 615
Condensation Products of Ethylenediamine with Adrenaline (Dr. Kunio Yagi and Dr. Toshiharu Nagatsu), 822
Condensed Tannins : Chemistry of (Plant Phenolics Group Discussion on), 1168
Conditioning (Recurrent), of Spinal Reflexes : Pattern of (Dr. V. J. Wilson, W. H. Talbot and F. P. J. Diecke), 824
Conductance (Electrical), and Dielectric Constant of the Interior of Erythrocytes (H. Pauly), 333
Conduction (Electric), in Semiconductors and Metals (Dr. W. Ehrenberg), *review* by Dr. P. T. Landsberg, 138
Conduction (Metallic), in the Crystal Compounds of Graphite (Prof. A. R. Ubbelohde, Dr. L. C. F. Blackman and J. F. Mathews), 454
Conduction Current (High-Field), in *n*-Hexane : Electric Strength and (A. M. Sletten), 311
Conductivity induced by Radiation in Polycrystalline Cadmium Sulphide and Polyethylene (C. G. Clayton, B. C. Haywood and Dr. J. F. Fowler), 1112
Conductivity Detectors (Thermal), in Gas Chromatography : Effect of the Carrier Gas on the Sensitivity of (Dr. B. A. Scott and Dr. A. G. Williamson), 1322

Conductors to Transistors : From, *review* by Dr. P. T. Landsberg, 138
Configuration of Poly-L-tyrosine : Optical Rotation and (A. R. Downie, Dr. A. Elliott and W. E. Hanby), 110
Configuration (Stable), of Methyl Groups in Dimethyl Ether (Katsumi Kimura and Masaji Kubo), 533
Configurational Stability of Deoxyribonucleic Acids : Dependence on Composition of the (Heterogeneity in Deoxyribonucleic Acids, I), (Dr. Julius Marmur and Prof. Paul Doty), 1427
Congenital Transmission of Toxoplasmosis through Successive Generations of Mice (Dr. J. K. A. Beverley), 1348
Congestion (Lymphatic) : Changes in Serum Transaminase Activity following Myocardial Damage due to (M. Foldi, Dr. P. Braun, Dr. M. Papp and Dr. I. Horváth), 1333
Congrès International de Prophylaxie Criminelle : First, 1783
Conidia : Detachment of, by Cloud Droplets (Dr. R. R. Davies), 1695
Conjugate (Electron-dense Antibody) : Preparation of an (Prof. S. J. Singer), 1523
Conjugate Point : 'Whistler Mode' Echoes remote from the (R. L. Dowden and G. T. Goldstone), 385
Conjugated Forms of Urobilinoid Pigments (I. L. Kahán and A. Kahán), 463
Conjugation : Glucuronide and Sulphate, *in vivo* and *in vitro* (K. H. Harper and G. Calcutt), 463
Conjugation *in vitro* (Biliyubin) : Factors affecting the Rate of (Dr. E. Talafant and J. Továrek), 111
Conn, jun., Dr. Rex B., and Davis, Dr. Richard B. : Green Fluorescence of Guanidinium Compounds with Ninhydrin, 1053
Connecticut Academy of Arts and Sciences : Memoirs, Vol. 13, The Systematics of North American *Daphnia* (Dr. John Langdon Brooks), 93
Connective Tissue : Human Muscular Dystrophy as an Aberration of the (Prof. Geoffrey H. Bourne and M. Nelly Golarz), 1741
Connective Tissue (Mammalian) : Polysaccharide Fibres in (A. J. Cruise and J. W. Jeffery), 677
Connective Tissue (Normal), of Tissue surrounding a Tumour and of Growing Rat Sarcoma : Collagen Content of (Maria Grabowska), 1186
Connell, J. J. : Aggregation of Cod Myosin during Frozen Storage, 664
Connell, Dr. P. H. : Amphetamine Psychosis, *review* by Dr. W. R. Bett, 639
Conscious Man : The Excitable Cortex in (Dr. Wilder Penfield), *review* by Dr. P. B. Bradley, 781
Consden, R., and Kohn, Dr. J. : Cellulose Acetate as a Medium for Immuno-Diffusion, 1512
Consequences of the Use of Nuclear Energy for the European Mode of Life (Council for Europe Competition for a thesis on), 509
Conservation Corps for Young Volunteers (Council for Nature), 508
Conservation (Nature), and Ecological Research, 205
Consolidated Gold Fields of South Africa, Ltd. Gold Medal for 1957-58 of the Institution of Mining and Metallurgy awarded to F. A. Williams, 1499
Consolidated Gold Fields of South Africa, Ltd. Premium for 1957-58 of the Institution of Mining and Metallurgy awarded jointly to H. H. Fraser and O. E. A. Somerset, 1499
Constant (Dielectric), of the Interior of Erythrocytes : Electrical Conductance and (H. Pauly), 333
Constituents of Human Haemoglobin—Separation of the Peptide Chains of Human Globin (Dr. V. M. Ingram), 1795 ; Comparison of Normal Adult Human Haemoglobin with Haemoglobin I by 'Fingerprinting' (Makio Murayama and Dr. V. M. Ingram), 1798 ; Formation of Normal and Doubly Abnormal Haemoglobins by Recombination of Haemoglobin I with S and C (Dr. Harvey A. Itano and Elizabeth Robinson), 1799
Constituents of Tobacco Smoke—an Annotated Bibliography (edited by H. R. Bentley and E. G. N. Berry), 1434
Constituents (Carbohydrate), of the Mycelium of *Penicillium chrysogenum* grown in Media with Different Sources of Carbon (Roshan J. Irani and Dr. K. Ganapathi), 758
Constituents (Cell), from C_2-Compounds : Biosynthesis of—Formation of Malate from Glycollate by *Pseudomonas ovalis* Chester (Dr. H. L. Kornberg and A. M. Gotto), 1791 ; Metabolism of Glycine by a Pseudomonad (A. G. Callely and Dr. S. Dagley), 1793 ; Formation of Glycerate from Oxalate by *Pseudomonas oxalaticus* OXI) grown in Oxalate (J. R. Quayle and Dr. D. B. Keech), 1794
Constitution of Lignin : Biosynthesis and (Prof. Karl Freudenberg), 1152
Consulting Scientists, Association of : Formation of, 651
  Election of Dr. J. G. Davis as chairman, 651
Consumption of Food, Intake of Water and Weight of Body in Rats : Effect of Reduction of Stimulation on (Dr. Karl Weiss and Harry M. B. Hurwitz), 344
Consumption (Oxygen), of Different Forms of Stable L *Proteus* P18 growing in Hypertonic Liquid Medium (Prof. P. Mandel, T. Terranova, M. Sensenbrenner and F. Feo), 194
Contact γ-Aluminium Oxide/Platinum : Structure and Mode of Action of the (Prof. Alfons Krause), 1615
Contamination by Extra-Terrestrial Exploration, 925
Continuous Culture : Lens Cells of the Calf in (Dr. J. van der Veen and C. F. A. Heyen), 1137
Contraction–Relaxation of Rat Tail Tendon : Effect of Cross-linking by Formaldehyde on the (Dr. H. R. Elden), 332
Contraction (Excitation–) Coupling in Heart Muscle (Prof. H. Reichel and A. Bleichert), 826
Contraction (Slow), of Smooth Muscle produced by Human Plasma (Dr. Yousry Gabr and Raga H. Aly), 897
Contraction and Relaxation in Smooth Muscles of Lamellibranch Molluscs (Dr. J. Lowy and B. M. Millman), 1730
Contrast Media (Radiographic) : Labelling of, with Iodine-131 (J. Liebster, J. Kácl and A. Babicky), 1474
Contributions to *Nature*, 15
Control : Handbook of Automation, Computation and (edited by Eugene M. Grabbe, Simon Ramo and Dean E. Wooldridge), Vol. 1, Control Fundamentals, *review* by P. H. Hammond, 1556
  Smoke, 1163
Control of Bud Reactivation in *Splachnum ampullaceum* (L.) Hedw. : Interaction between Kinetin and Indoleacetic Acid in the (Prof K. E. von Maltzahn), 60
Control of Diapause by an 'Internal Clock' in *Anthrenus verbasci* (L.) (Col., Dermestidae), (G. M. Blake), 126
Control of Dust and Fumes in Industry (British Occupational Hygiene Society Conference on), 865
Control in Electrical Engineering : Measurement and (Dr. A. H. M. Arnold), 89
Control of Exhaust Fumes, 1092
Control of Leaf Senescence by Auxins (Daphne J. Osborne), 1459
Control of Superficial Scald in Stored Apples (W. Hugh Smith), 760
Control (Feedback), of Purine Biosynthesis by Purine Ribonucleotides (Dr. James B. Wyngaarden and Doris M. Ashton), 747
Control (Genetic), of Chromosome Pairing in Intergeneric Hybrids with Wheat (Dr. Ralph Riley, Victor Chapman and Gordon Kimber), 1244
Control (Genetic), of Human Haptoglobin Synthesis (Dr. A. C. Allison), 1312
Control (Genetic), of Industrial Melanism in the Lepidoptera : New Aspects of the (Dr. H. B. D. Kettlewell), 918
Control (Structural), of Polymorphism in Micas (E. W. Radoslovich), 253
Control (Temperature), of Physiological Dwarfing in Peach Seedlings (Prof. Bruce M. Pollock), 1687
Control Engineers : Education of Instrument Technologists and (J. F. Coales), 1433
Control Fundamentals, *review* by P. H. Hammond, 1556
Control and Instrumentation : Nuclear Reactor (J. H. Bowen and E. F. O. Masters), *review* by R. Vaux, 1149
Control and Instrumentation of Reactors (Harwell Reactor School Second Course on), 153
Control Loop in Singing : Nature of the Vibrato and the (Dr. J. A. Deutsch and J. K. Clarkson), 167
Control Systems : Feedback (Prof. Otto J. M. Smith), *review* by M. J. Somerville, 73
Control Theory : Basic Automatic (Prof. Gordon J. Murphy), *review* by M. J. Somerville, 211
Controlled Lighting : Effect of, on Production Characters in the Fowl (J. C. Bowman and J. D. H. Archibald), 1138
Conversion of Caffeic Acid to Esculetin during Paper Chromatography (Warren L. Butler and H. W. Siegelman), 1813
Conversion of Quinic Acid to Shikimic Acid in Roses : Evidence for the (L. H. Weinstein, C. A. Porter and H. J. Laurencot, jun.), 326
Conversion (Gene) : A Position-Effect Explanation of (Prof. J. A. Serra), 700
Conversion (Polymorphic), of Mercuric Iodide on Alumina (Prof. Harry Zeitlin and Harry Goya), 1041
Conway (River) : Feeding of the Oystercatcher (*Haematopus ostralegus*) on the Edible Mussel (*Mytilus edulis*) in the Estuary of the (R. E. Drinnan), 153
Cooch, Dr. F. G., and Beardmore, Dr. J. A. : Assortative Mating and Reciprocal Difference in the Blue–Snow Goose Complex, 1833
Cook, Dr. A. M. : The Killing of Micro-organisms, *review*, 277
Cook, C. D., and others : Copper–Cellulose Complexes, 988
Cook, Dr. J. W. : Appointed to the Board of the College of Technologists, 1500
  The Role of the Scholar in Society, 1772
Cook, Margaret J., and others : Measuring Productivity in Breeding of Small Animals, 339
Cooke, Dr. G. W. : Phosphates and Organic Substances in Nitrogen Deficiency, 513
Coombs, Dr. M. M., and Danielli, Prof. J. F. : Chlorination of Proteins as a Method of Increasing their Opacity in the Electron Microscope, 1257
Cooper, Edmund J. : Appointed general secretary of the Scientific Film Association, 18
Cooper, Susan C. (Graham, Dr. John W., and) : Biological Origin of Manganese-rich Deposits of the Sea Floor, 1050
Co-operation Administration, International : Technical Assistance Programmes of the, 1163
Co-operation (Scientific), within the British Commonwealth (H.R.H. the Duke of Edinburgh), 425
Co-operation (Scientific), in the Commonwealth, 775
Co-operation (Technical) in Africa South of the Sahara, Commission for (Food and Agriculture Organization of the United Nations and the) : Technical Meeting on Legumes in Agriculture and Human Nutrition, 439
Co-operative Economic Development in South and South-East Asia, Colombo Plan for : Seventh Annual Report of the Consultative Committee (Seattle, 1958), 1000
Co-operative Phenomena and Phase Transitions (Physical Society Conference on), 1234, 1643
5-Co-ordination of Divalent Copper (Dr. D. P. Graddon), 1610
Co-ordination (Tetra-) of Nickel (II)—some Complexes with *Cyclo*hexylphosphine (Dr. Aldo Turco, Dr. Vladimiro Scatturin and Dr. Giovanni Giacometti), 601
Co-ordination (Tetrhedral), in Ni(II), (Dr. L. I. Katzin), 1672 ; (Prof. E. C. Lingafelter), 1673
Co-ordination Chemistry (Chemical Society, sponsored by the International Union of Pure and Applied Chemistry, Fourth International Conference on), 1784
Co-ordination Compounds (Transition Metal) : Explosion of (Seward E. Beacom), 38
Cope, F. W. (Bennett, M. C., and) : Nuclear Fusion and Non-Fusion in *Theobroma cacao* L., 1540
Copepod *Elaphoidella gracilis* (Sars) : Haemoglobin and the Habitat of the Harpacticoid (J. Green), 1834
Copley, Dr. A. L., and others : Anticoagulant Action of Fibrin Surfaces on Mammalian Blood, 1683
Co-polymers (Block and Graft) : Stereo-specific Polymers and (Bradford Institute of Technology Course on,), 224
Copp, D. J. B. : Reorganization of Microbiological Research in Britain, 416
Copper : Catalytic Action of, in the Alkaline Autoxidation of Cellulose at Low Alkali Concentration (R. I. C. Michie and Dr. S. M. Neale), 534
  The De Haas-Van Alphen Effect in (Dr. D. Shoenberg), 171
  Destruction of Cortisone and related Steroids by Traces of, during Purification Procedures (Marvin L. Lewbart and Vernon R. Mattox), 820
Copper in Fungal Laccase : An Electron Spin Resonance Study of the State of (Dr. Bo G. Malmström, Dr. Rolf Mosbach and Dr. Tore Vänngård), 321

Copper (Divalent) : 5-Co-ordination of (Dr. D. P. Graddon), 1610
Copper Sheet (Rolled) : Nuclear Magnetic Resonance in (E. A. Faulkner), 1043
Copper Uptake (Iodine and), by Soil Organic Matter (J. M. Northmore), 1309
Copper–Cellulose Complexes (Dr. D. S. Belford, C. D. Cook, E. H. Nevard and Prof. R. D. Preston), 988
Copper–Chrome–Arsenate Wood Preservatives : Abnormal Resistance of *Poria vaillantii* (D. C. ex Fr.) Cke. Strains to (E. W. B. Da Costa), 910
Corals irradiated with Ultra-Violet Rays : Fluorescence Effects from (Dr. R. Catala-Stucki), 949
Corals and Marine Plants : Chlorophyll *a* in some (Dr. Paul R. Burkholder, Lillian M. Burkholder and Juan A. Rivero), 1338
Corby, G. A. : Automatic Reduction of Geophysical Data (Preliminary Tests on the Preparation of Numerical Forecasts with the aid of a Computer), 1167
Corday—Morgan Medal and Prize for 1957 awarded by the Chemical Society to Prof. G. W. Kenner, 792
Core (Earth's) : Fusion Curve of Iron to 96,000 Atmospheres—Temperature of the (Dr. H. M. Strong), 1381
Coregonids : Gas Secretion in (Dr. S. Sundnes), 986
Coriaria : Records of Nodulation in (R. E. R. Grimmett), 223
Corixidae (Hemiptera-Heteroptera) : Respiration of (Dr. Edward J. Popham), 914
'Corkscrew-sperms' associated with Sterility in Bulls : A Rare Sperm Abnormality—(Dr. Erik Blom), 1280
Corlett, W. J. : Title of reader in political economy in the University of London (at University College) conferred on, 368
Corn Plant: An Antifungal Substance in the, and its Effect on Growth of Two Stalk-rotting Fungi (N. J. Whitney and C. G. Mortimore), 341
Cornell University : Annual Summer Laboratory Course in Techniques and Applications of the Electron Microscope, 1094
Corner, Dr. E. J. H. : Vegetation of the Humid Tropics, 795
Cornish, E. H., and Cutting, D. M. : A Dose Test for Irradiated Polyethylene, 1804
Cornish, Dr. F. H. J. : Appointed lecturer in applied mathematics at the University of Leeds, 1024
Cornwall, Dr. I. W. : Soils for the Archaeologist, *review* by Dr. Alex Muir, 1355
Corona (Solar) : A New Theory of the (Prof. Paul J. Kellogg and Prof. Edward P. Ney), 1297
  Radio Reflexions from the Moon and (Prof. O. Burkard), 1180
Coronary Arteries and Circulus Willisii of Atherosclerotic Individuals : Composition of Lipids isolated from the Aorta, (Prof. C. J. F. Böttcher, F. P. Woodford, C. Ch. Ter Haar Romeny, E. Boelsma and C. M. Van Gent), 47
Coroniti, S. C., and others : Geophysical Effects of High-Altitude Nuclear Explosions, 1476
Corpuscular Radiation and the Acceleration of Artificial Satellites (Dr. Luigi G. Jacchia), 1662
Corpuscular Radiation (Low-Energy), at High Latitudes (K. D. Cole), 738
Correlation with Iodine-131 in Milk : Increase in Background Gamma-Radiation and its (Measurements at Leeds following the Windscale Reactor Accident), (Prof. F. W. Spiers), 517
Correlation between Iodine Permeability and the Gram Characteristic of Cells (Prof. J. W. Bartholomew, Thomas Cromwell and Harold Finkelstein), 123
Correlation of Sedimentation-Rates by Dimensionless Groups (Colin Harris), 530
Correlation (Genetic), between Two Traits in the House Mouse (*Mus musculus*) : Selection for Relationships Opposite to those predicted by the (F. Cockrem), 342
Correlations (Growth) : Gibberellic Acid and (Prof. R. Dostál), 1338
Correspondence of Sir Joseph Banks, *review* by Dr. W. B. Turrill, 1353
Corrosion, International Congress on : Proposal that it be held in London in 1961, 1094
Corrosion Engineers, British Association of : Formation of, 1779
Cortex (Cerebral) : Electron Microscopy of Synaptic Contacts on Dendrite Spines of the (Dr. E. G. Gray), 1592
  Recurrent Inhibition in (Dr. Roger M. Morrell), 979
Cortex (The Excitable), in Conscious Man (Dr. Wilder Penfield), *review* by Dr. P. B. Bradley, 781
Cortical (Adrenal) Function in the Pregnant Sheep (Kathleen W. Robinson), 690
Corticotropins : Patterns in the Amino-Acid Sequences of the (Drew Schwartz), 464
Cortisone : Effect of Amniotic Fluid on Inhibition of Growth by, in Chicken Embryos (Dr. P. de Franciscis and Prof. W. Landauer), 617
Cortisone and related Steroids : Destruction of, by Traces of Copper during Purification Procedures (Marvin L. Lewbart and Vernon R. Mattox), 820
Cosmetic Chemists : International Federation of Societies of (Formation of an), 1366
Cosmetic Chemists, Society of : British Congress of Cosmetic Science, 934
Cosmetic Science : British Congress of (Society of Cosmetic Chemists), 934
Cosmic Dust in the Atmosphere (Dr. D. W. Parkin and W. Hunter), 732
Cosmic Radiation and the Weather (Prof. Edward P. Ney), 451
Cosmic-Ray Equator and the Geomagnetic Dip Equator : Difference between (Takashi Oguchi and Masahiro Kodama), 103
Cosmic-Ray Exposure Ages of Meteorites : Calculation of Erosion in Space from the (Dr. F. L. Whipple and Dr. E. L. Fireman), 1315
Cosmic-Ray Intensity : Storm-Time Increase of (Prof. Sekiko Yoshida and Masami Wada), 381
Cosmic-Ray Showers, *review* by Dr. R. M. Tennent, 1555
Cosmogenic Noble Gases in the Washington County Meteorite (Oliver A. Schaeffer and David E. Fisher), 660
Cosmology (Dirac's), and the Dating of Meteorites (Prof. R. H. Dicke), 170
Cossins, E. A., and Turner, Dr. E. R. : Utilization of Alcohol in Germinating Pea Seedlings, 1599
Cosslett, Dr. V. E. : Microscopy with X-Rays, 1423
Cotinine, an Oxidation Product of Nicotine formed by Rabbit Liver (Howard B. Hucker, James R. Gillette and Bernard B. Brodie), 47
Cotten, J. : Chromosome Number of the Potato Root Eelworm, *Heterodera rostochiensis* Wollenweber, 128
Cotton, F. A., and Holm, R. H. : Co-ordination Chemistry (Physical Properties and Relative Stabilities of the various types of Cobalt (II) Complex in Solution), 1784
Cotton, Jack : Gift of £100,000 to the Royal College of Surgeons, to establish a chair of biochemistry, 579
Cotton Industry War Memorial Trust Scholarship (Textile Institute), 933
Cottrell, Prof. A. H. : Nuclear Reactor Metallurgy, *review*, 1628
Cottrell, Prof. A. H. (Barnes, R. S., and) : Interfacial Phenomena (Annealing of Radiation Damage in Copper produced by Bombardment with α-particles), 1099
Cottrell, Dr. T. L. : Appointed to the chair of chemistry in the University of Edinburgh, 151 ; work of, 151
  Relaxation Processes (Measurements of Ultrasonics in Gases), 584
Cotzias, Dr. George C., and Greenough, Dr. James J. : Quantitative Estimation of Amineoxidase, 1732
Coulometric Titration Method (An Automatically Operating), for continually Measuring Small Amounts of Water in Fluids (E. Barendrecht), 1181
Coulson, Prof. J. M. : Fluid Systems in Chemical Engineering, *review*, 492
Coumarin : Effect of, on the Germination and Growth of Rice Seedlings (Dr. G. Misra and S. N. Patnaik), 989
Council for Europe : Competition for a thesis on Consequences of the Use of Nuclear Energy for the European Mode of Life, 509
Council for Science and Technology of Western Germany (Dr. J. Horne), 512
Counsell, J. F. : Awarded a Ciba Fellowship for 1959-1960, 1161
Counter, E. R. (Sutcliffe, Dr. J. F., and) : Absorption of Alkali Cations by Plant Tissue Cultures, 1513
Countercurrent (Pacific Equatorial) : Measurements of the (John A. Knauss and Robert Pepin), 380
Countries (Under-developed) : Educational Advancement and the, 633
  National Food Reserve Policies in (United Nations Food and Agriculture Organization, FAO Commodity Policy Studies No. 11), 635
Countryside in Britain : Preservation of the, 917
Coupling (Energetic), in the Respiratory Chain (Dr. Poul E. Glahn and Dr. Sigurd O. Nielsen), 1578
Course on the Control and Instrumentation of Reactors (Harwell Reactor School), 153
Course in Polarography (British Polarographic Research Society), 18
Course for Senior Technical Executives in Industry at the Harwell Reactor School (Atomic Energy Research Establishment), 224
Course on Stereospecific Polymers and Block and Graft Co-polymers (Bradford Institute of Technology), 224
Course (Annual Summer Laboratory), in Techniques and Applications of the Electron Microscope (Cornell University), 1094
Course (Postgraduate), in Biochemical Engineering (University College, London), 933
Course (Postgraduate Lecture), on Recent Advances in Protein Chemistry (Department of Chemistry, Biology and Geology of the Kingston Technical College), 86
Courses at the Harwell Reactor School, 153, 224, 1643
Courses in Statistics and Computational Methods : Scholarships in Mathematics for (London School of Economics and Political Science), 85
Courses (College Biology), on Television, 649
Courses (International), on Nuclear Energy (European Nuclear Energy Agency of the Organization for European Economic Co-operation), 1163
Courses (Summer), of the International School of Physics of the Societá Italiana di Fisica, 1368
Courses (Training) : Grants for (United States Atomic Energy Commission), 437
Courses (Training), at the Shippingport Atomic Power Station (United States Atomic Energy Commission), 153
Courtauld, Augustine : *Obituary* by Prof. L. R. Wager, 930
Courts, Dr. A., and Stainsby, Dr. G. : At the sixteenth meeting of the Research Panel of the British Gelatine and Glue Research Association (Solubilized Collagen), 440
Coussmaker, C. R. C., and collaborators : Co-ordination Chemistry (Properties of the Versatile Complexes of Nickel (II) with Substituted Phosphines), 1784
Coutts, H. H., and others : Drift of Toxic Chemicals released from a Low-flying Aircraft, 131
Cover on River Bottoms (Dr. D. Scott and Dr. J. M. Rushforth), 836
Cowling, Prof. T. G. : Magnetic Field of the Earth, 937
Cows with Hypocupraemia : Iron Content in the Serum of (Dr. Rajmund Rys), 1596
Cox, A. P., and others : Molecular Symmetry in *Cyclo*pentadienyl Thallium and some related Substances from their Microwave Spectra, 1182
Cox, C. B. : Awarded a Harkness Fellowship for 1959 of the Commonwealth Fund, 1093
Cox, Dr. D. R. : Planning of Experiments, *review* by Dr. D. J. Finney, 1766
Cox, Dr. Edward H. : Appointed deputy Science Officer in the American Embassy in Paris, 15
Cox, H. L. : Awarded the George Taylor (of Australia) Gold Medal of the Royal Aeronautical Society, 1648
Cox, Dr. R. N. : Hypersonic Flow (General Characteristics of Hypersonic Flow Fields), 1095
Cox, S. F., and others : Metal-Chelating Properties of Plant-Growth Substances, 1176
Crab-paralysing Agent of the Posterior Salivary Glands of Cephalopods : Cephalotoxin, the (Dr. F. Ghiretti), 1192
Crabs (Shore), *Carcinus maenas* Pennant (Sacculinized) : Behaviour of (Erik Rasmussen), 479
Crabtree, Dr. L. F. : Hypersonic Flow (Hypersonic Boundary Layers with special reference to Aerodynamic Heating), 1095
Crabtree Effect with Ehrlich Ascites Carcinoma Cells : Energy Compensation in the (K. H. Ibsen, E. L. Coe and Dr. R. W. McKee), 1471
Crafts, A. S. (edited by, in association with Machlis, Leonard, and Torrey, John G.) : Annual Review of Plant Physiology, Vol. 9, *review* by Prof. W. Stiles, 1703
Craggs, Prof. J. D. : Gas Discharges (Effect of Electrons on the Broadening of the Balmer Lines), 92
Craik (Kenneth) Research Award : Election to the (St. John's College, Cambridge), 18
Cramer, Robert : Zone Electrophoresis of Rous Sarcoma Virus, 195
Crampton, C. B. : Heavy Minerals in certain Old Red Sandstone and Silurian Limestones of Monmouth, 485

Crane, Dr. E. J. : At the International Conference on Scientific Information (The Importance of Indexing), 148
Cranes (Crowned), in Cambridgeshire (Simon B. Jones and Philip E. H. Jones), 560
Cranston, Dr. Hoy A., and Eggert, Frederick O. : Homologous Species Neoplastic Antibodies, 1471
Crary, Albert P. : Appointed chief scientist of the United States Antarctic Research Programme, 1090 ; work of, 1090
Craters on the Moon, 864
Craters (Lunar) : Simulation of—a Blow-hole Theory (Dr. A. G. Gaydon and R. C. M. Learner), 37
Craters (Lunar), and Maria : Origin of the (Prof. Zdenek Kopal), 169, 737 ; (Dr. William G. van Dorn), 737
Craven, Dr. B., and Jeffrey, Prof. G. A. : Structure of Malvalic Acid and some related C_{18} and C_{19} *Cyclo*propane Fatty Acids, 676
Crawford, Dr. J. D., and Kennedy, Dr. G. C. : Chlorothiazid in Diabetes Insipidus, 891, 1368
Crawley, W. E., and Dodd, D. C. : A Bacterium with Fungicidal Activity, 63
Creating Chromosomal Aberrations : A New Physical Method of (Dr. John H. Heller and Dr. A. A. Teixeira-Pinto), 905
Creation of the College of Technologists, 1500
Cremer, Herbert W., and Davies, Trefor (edited by) : Chemical Engineering Practice, Vol. 5, Fluid Systems I, *review* by Prof. J. M. Coulson, 492
Creole Foundation : Prize for a work on any aspect of Venezuela in the fields of Natural, Physical or Social Sciences, 368
Cretaceous Basalts of Madagascar : Remanent Magnetism of the (Dr. A. Roche and L. Cattala), 1049
Creyssel, Dr. R. (Fine, Dr. J. M., and) : Starch Gel Electrophoresis Studies on Abnormal Proteins in Myeloma and Macroglobulinaemia, 392
Crick, Dr. F. H. C. : Elected a Fellow of the Royal Society, 860
Criterion derived from the Distortion Spectrum : Unpleasantness of Distorted Sounds—a (E. R. Wigan), 1320
Critical Test of Antigenic Relationships (Dr. J. G. Feinberg and Hazel Grayson), 987
Critique of Wittgenstein's Philosophy, *review* by F. I. G. Rawlins, 494
Croatto, Prof. U. (Bruno, M., and) : Structural Chemistry of Promethium, 601
Croft, Dr. A. J. : Hydrogen Liquefaction and Associated Techniques (The Question of Safety), 1505
Crofton, H. D., and Yonge, P. G. : Parasitology (Control of *Diphyllobothrium* Infections in Trout), 1507
Cromartie, Dr. R. I. T. : Naturally Occurring Quinones, *review*, 1291
Crombie, Dr. W. Mary, and Ballance, P. E. : Synthesis of Long-Chain Fatty Acids from 2-^{14}C-Acetate and ^{14}C-Glucose in *Trichoderma viride*, 1195
Cromwell, Thomas, and others : A Correlation between Iodine Permeability and the Gram Characteristic of Cells, 123
Crook, E. M. (organized and edited by) : Biochemical Society Symposium on Metals and Enzyme Activity (Leeds, 1956), *review* by Dr. O. T. G. Jones, 968
Crosfill, M. L., and others : Variation of Sensitivity to Ionizing Radiation with Age, 1729
Crossland, Dr. B. : Appointed to the chair of mechanical engineering at the Queen's University, Belfast, 1779 ; work of, 1779
Cross-linked Polystyrene : Immunochemically Active (L. H. Kent and J. H. R. Slade), 325
Cross-linking by Formaldehyde : Effect of, on the Contraction–Relaxation of Rat Tail Tendon (Dr. H. R. Elden), 332
Cross-linking of Rubber Hydrocarbons by High-Energy Radiation : Estimation of Chain Fracture during the (Dr. L. Mullins and Dr. D. T. Turner), 1547
Cross-linking (Radiation-induced), of Polyvinyl Chloride : Enhancement of (Dr. S. H. Pinner), 1108
Crowcroft, Peter, and Ingles, Jean M. : Seasonal Changes in the Brain-case of the Common Shrew (*Sorex araneus* L.), 907
Crown-Gall Tumour-inducing Principle : *In vitro* Synthesis of the (Alan J. Thomas and Richard M. Klein), 113
Crowned Cranes in Cambridgeshire (Simon B. Jones and Philip E. H. Jones), 560
Cruickshank, Helen Gere (edited by) : John and William Bartram's America, *review* by Dr. L. Harrison Matthews, 1006
Cruickshank, Prof. R. : Elected a Fellow of the Royal Society of Edinburgh, 719
Cruise, A. J., and Jeffery, J. W. : Polysaccharide Fibres in Mammalian Connective Tissue, 677
Crumb (Bread) : Moisture Content of Whole Bread and (Y. Pomeranz), 1222
Crumbs (Soil) : Stability of (Dr. W. W. Emerson), 538
Crust (Earth's), in Antarctica : Thickness of the (F. F. Evison, C. E. Ingham and R. H. Orr), 306
Crustacean Eye (Euphausiid) : Electrical Response to Illumination of the (Elizabeth M. Kampa, Brian P. Boden and Bernard C. Abbott), 1820
Crystal (Quartz) : Sintering of (A. C. D. Chaklader and Prof. A. L. Roberts), 1252
Crystal Compounds of Graphite : Metallic Conduction in the (Prof. A. R. Ubbelohde, Dr. L. C. F. Blackman and J. F. Mathews), 454
Crystal Lattices : Spacing Anomaly in Electron Microscope Images of (Dr. H. Hashimoto and Dr. H. Yotsumoto), 1001
Crystal Structure of Calcium Thymidylate (P. Horn, Dr. V. Luzzati and Dr. K. N. Trueblood), 880
Crystal Structure of Foshagite ($Ca_4Si_3O_9(OH)_2$), (Dr. J. A. Gard and Dr. H. F. W. Taylor), 171
Crystal Structure of β-Glycine (Dr. Yoichi Iitaka), 390
Crystal Symmetry of Struvite (Guanite), (J. A. Bland and S. J. Basinski), 1385
Crystalline Fluors (Solid) : Radioassay of Aqueous Solutions mixed with (Dr. Daniel Steinberg), 1253
Crystallization of Gramicidin (P. E. Olesen and L. Szabo), 749
Crystallographic Orientation of Nodules formed by the Grain Boundary Reaction of Aluminium–Zinc Alloys (Dr. Ryoji Watanabe and Dr. Shigeyasu Koda), 1667
Crystals : Synthetic Quartz (Western Electric Company and the Bell Telephone Laboratories), 294
Crystals of Riboflavin making up the Tapetum Lucidum in the Eye of a Lemur (Antoinette Pirie), 985
Crystals (Ammonium Dihydrogen Phosphate) : Effect of Tartar Emetic on the Growth of (Yutaka Kunisaki), 105
Crystals (Finback Whale Myoglobin) : Electron-Microscopic Study of (D. E. Bradley), 941
Crystals (Liquid), of Lipid in Normal and Atheromatous Tissue (G. T. Stewart), 873
Crystals (Pure and Decomposed), of Thallous Azide : Absorption Spectra and Associated Photoconductivity of (B. L. Evans and A. D. Yoffe), 1241
Crystals (Synthetic Quartz) : Use of, as a Support for Specimens in Powder Photographs (Hitosi Hagihara, Shuji Yamashita and Akitsu Takeda), 1666
Csillik, Dr. B. : Submicroscopic Organization of Post-synaptic Membranes, 1684
Ctenophore (Planktonic), *Pleurobrachia globosa* Moser 1903, from the Madras Coast : Metacercaria (Allocreadioidea) in the (Sita Anantaraman), 1407
Cubic Chromium–Iron and Chromium–Manganese Alloys : Low-Temperature Specific Heats of Body-centred (C. T. Wei, C. H. Cheng and Prof. P. A. Beck), 315
Cubic Equation Machine (Soddy's), handed over to the Science Museum, London, 863
Cultivated Sorghums (Nigerian) : A Chemical Basis for the Classification of Glume Colour in (W. R. Stanton, T. B. Miller and D. L. Curtis), 807
Cultivation (*In vitro*), of the Histotrophic Stages of *Haemonchus contortus* and *Ostertagia* spp. (Dr. Paul H. Silverman), 197
Cultivation of Science, Indian Association for the : Annual Report for 1957-58, 1789
Cultural Affairs : International, 1569
Culture : Morphogenetic Response of *Citrus* Ovules to Growth Adjuvants in (N. S. Ranga Swamy), 735
Culture (Continuous) : Lens Cells of the Calf in (Dr. J. van der Veen and C. F. A. Heyen), 1137
Culture (Sterile), of Roots : A Technique for the (Dr. N. S. Cohn and Dr. T. Merz), 412
Culture (Tissue) : Antibody Formation in (Marvin Fishman), 1200
Culture (Tissue), and Liver Antigens of Mouse Hepatitis : Complement Fixation with (Dr. Theodore J. Starr and Dr. Morris Pollard), 1690
Culture Cells (Tissue) stained with Acridine Orange : Fluorescence of (U. N. Joshi and Dr. K. S. Korgaonkar), 400
Culture-filtrate of *Vibrio cholerae* : Enterotoxicity of Bacteria-free (Prof. S. N. De), 1533
Cultures : Some South African Stone Age (Dr. R. J. Mason), 377
Cultures of certain Micro-organisms growing in Defined Glucose-containing Media : Detection of Gentiobiose and Sophorose in (A. W. Khan, D. N. Pellegrino and Prof. T: K. Walker), 682
Cultures (Plant Tissue) : Absorption of Alkali Cations by (Dr. J. F. Sutcliffe and E. R. Counter), 1513
Cultures (*Spirogyra pratensis*) : Formation of Purple Pigment in (Dr. Ann Allen and Dr. R. E. Alston), 1064
Cunningham, Sir Graham : Elected to Fellowship of the Imperial College of Science and Technology, 1161
Cunningham, Prof. G. J., and others : Chemical Changes in Human Bronchial Epithelium and their relation to Bronchial Cancer, 1743
Curator, Vol. I, No. I (American Museum of Natural History), 223
Curing Brines (Fish and Meat) : The Microbiology of—Proceedings of the Second International Symposium on Food Microbiology (Cambridge, 1957), (edited by Dr. B. P. Eddy), *review* by Dr. Magnus Pyke, 351
Curious Naturalists (Dr. Niko Tinbergen), *review*, 211
Curnow, R. N. : Awarded a Harkness Fellowship for 1959 of the Commonwealth Fund, 1093
Current (High-Field Conduction), in *n*-Hexane : Electric Strength and (A. M. Sletten), 311
Current (Peru), off the Chilean Coast : Relationship between the Hake Fishery and a Southerly Sub-surface Return Flow below the (Dr. Wilhelm Brandhorst), 1832
Current Developments in the Production of High Vacua (Institute of Physics Symposium on), 368
Currents : Turbidity (Royal Astronomical Society Discussion on), 657
Curry, Dr. A. S. : Identification of Barbiturates, 1052
Curtis, D. L., and others : A Chemical Basis for the Classification of Glume Colour in Nigerian Cultivated Sorghums, 807
Curtis, Dr. D. R., and others : Chemical Excitation of Spinal Neurones, 611
Curtis, H. : *Obituary*, 1778
Curve (A Survival), for Mammalian Cells irradiated *in vivo* (Dr. H. B. Hewitt and C. W. Wilson), 1060
Curzon, Dr. G., and Vallet, L. : Preparation of Caeruloplasmin from the *G2* Fraction of Human Plasma, 751
Cusick, Dr. F. : Experimental Approaches to the Problems of Growth and Form in Plants (Floral Morphogenesis in *Primula bulleyana*), 585
Cuthbertson, Dr. D. P. : Function of the Rumen, 1644
Cutter, Dr. E. G. : Experimental Approaches to the Problems of Growth and Form in Plants (Changes in Leaf Arrangement in Individual Fern Apices), 585
Cutter, Dr. E. G., and others : Use of Radioactive Tracers in Studies of the Shoot Apex, 1580
Cutting, D. M. (Cornish, E. H., and) : A Dose Test for Irradiated Polyethylene, 1804
Cuttings (Clematis): Effect of Boron on the Rooting of (Dr. C. J. Weiser), 559
Cuzin, Dr. J. : Phosphates and Organic Substances in Nitrogen Deficiency, 513
Cyanamid European Research Institute, Inc., Geneva, 720
Cyanamid International Information Service : Technical Papers, 1433
Cyanea capillata (Jelly-fish) : The Amphipod, *Hyperia galba*, an Ectoparasite of the (Prof. Erik Dahl), 1749
Cycles : Nuclear Fuel (Institute of Physics, in collaboration with the British Nuclear Energy Conference Symposium on), 1646
Cyclic Allylic Alcohol : Effect of Alkali Salts on the Steric Course of Hydrogenation of a (M. C. Dart and Prof. H. B. Henbest), 817
Cyclic Alternating-Current Voltammetry with a Platinum Electrode (André L. Juliard), 1040
*Cyclo*Hexadienes (Highly Fluorinated) : Thermal Reactions of (B. Gething, Dr. C. R. Patrick and Prof. J. C. Tatlow, and Dr. R. E. Banks, Dr. A. K. Barbour and A. E. Tipping), 586
*Cyclo*heximide (Actidione) : Reversal of Antibiotic Action of, by Bivalent Metal Ions (M. Blumauerová and J. Stárka), 261

*Cyclo*hexylphosphine : Tetra-co-ordination of Nickel (II)—some Complexes with (Dr. Aldo Turco, Dr. Vladimiro Scatturin and Dr. Giovanni Giacometti), 601
*Cyclo*pentadienyl Thallium : Molecular Symmetry in, and some related Substances from their Microwave Spectra (J. K. Tyler, A. P. Cox and Dr. J. Sheridan), 1182
*Cyclo*propane Fatty Acids (C_{18} and C_{19}) : Structure of Malvalic Acid and some related (Dr. B. Craven and Prof. G. A. Jeffrey), 676
Cyprus : Birds of (Dr. David A. Bannerman and W. Mary Bannerman), *review* by Sir Landsborough Thomson, 967
Cystamine and 5-Hydroxytryptamine in Irradiated Rats : Effect of High Oxygen Pressure on the Protective Action of (H. A. S. van den Brenk and Ruth Moore), 1530
Cyst(e)ine Content : Differences in, between Vegetative Cells and Spores of *Bacillus cereus* and *Bacillus megaterium* (Vladimír Vinter), 998
Cystine : Inhibition of Growth and Respiration of *Ophiobolus graminis* var. *avenae* and *Aspergillus niger* by (Elizabeth M. C. Turner), 1130
'Cystine Disulphoxide' : Structure of (B. J. Sweetman), 744
Cytochemical Methods : General (edited by Prof. J. F. Danielli), Vol. I, *review* by Dr. R. Barer, 1355
Cytology at Dublin, 1716
Cytopathogenic Agent from a Mammary Tumour in a *C3H* Mouse that produces Tumours in Swiss Mice and Hamsters (Dr. E. A. McCulloch, A. F. Howatson, L. Siminovitch, A. A. Axelrad and A. W. Ham), 1535
Cytoplasm (Bacterial) : Effect of Drugs upon Components of (Dr. S. Dagley and J. Sykes), 1608
Cytostatic Agent : 1,6-Di-(2-Bromoethylamino)-1,6-Dideoxy-D-Mannitol Dihydrobromide—a New (L. Vargha and T. Horváth), 394
Czanik, Pál (Tárnok, Iván, and) : Malachite Green-reducing Enzyme in *Mycobacteria*, 549
Czechoslovak Academy of Sciences, and the Purkyne Medical Society : Symposium on Antibiotics, 154
Czechoslovakia : Plant Physiology in (Prof. Walter Stiles), 369

DA COSTA, E. W. B. : Abnormal Resistance of *Poria vaillantii* (D. C. ex. Fr.) Cke. Strains to Copper–Chrome–Arsenate Wood Preservatives, 910
Daams, H., and others : Canadian Caesium-Beam Standard of Frequency, 575
Dachille, Frank, and Roy, Prof. Rustum : The Spinel–Olivine Inversion in Mg_2GeO_4, 1257
Dacie, Prof. J. V. : Hemophilia and Hemophilioid Diseases, *review*, 1221
Dagley, Dr. S., and Sykes, J. : Effect of Drugs upon Components of Bacterial Cytoplasm, 1608
Dagley, Dr. S. (Callely, A. G., and) : Biosynthesis of Cell Constituents from C_2-Compounds—Metabolism of Glycine by a Pseudomonad, 1793
Dahl, Prof. Erik : The Amphipod, *Hyperia galba*, an Ectoparasite of the Jelly-fish, *Cyanea capillata*, 1749
Dahlia variabilis Desf. : Leaf-Enations in, induced by Tomato Spotted Wilt Virus (A. A. Brunt), 627
Dahn, Prof. H., and others : Oxidation of Ascorbic Acid and similar Reductones by Nitrous Acid, 163
Dairy Heifers : Effect of Clipping the Coat on the Thermoregulatory Reactions of (H. Berman and H. H. Kibler), 606
Dairy Microbiology (Prof. Edwin M. Foster, Prof. F. Eugene Nelson, Prof. Marvin L. Speck, Prof. Raymond N. Doetsch and Prof. Joseph C. Olson, Jr.), *review* by Dr. C. A. E. Briggs, 637
Dairying, National Institute for Research in : Appointment of Prof. R. G. Baskett as director, 294, 365
Dale, C. H. A. : *A Priori* Probabilities in Gambling, 842
Dale, Sir Henry : Elected an honorary member of the Biochemical Society, 18
Dalhousie University, Halifax : Awarded an annual grant of 90,000 dollars by the National Research Council of Canada, for the establishment of an Institute of Oceanography, 1161
  Appointment of Prof. F. R. Hayes as director of the Institute of Oceanography, 1161
Dallam, R. Duncan, and others : Partition of Selenium-75 in the Intracellular Particulate Matter of Rat Liver, 183
Dalton, John : The Biographical Approach to (Frank Greenaway), *review* by Prof. J. R. Partington, 1765
Dalton, Rodger G. (Fisher, Edward W., and) : Cardiac Output in Cattle, 829
Dalziel, J., and others : Lowest Oxidation States of Technetium and Rhenium, 1755
Dalziel, Dr. J. M. (Hutchinson, Dr. J., and) : Flora of West Tropical Africa, second edition revised by R. W. J. Keay, *review* by A. W. Exell, 6
Damage (Brain) : Oxygen Exposure and (Lars Gyllenstein), 1068
Damage (Chemical Radiation) : Thermal Annealing of (Dr. A. G. Maddock and S. R. Mohanty), 86
Damage (Freezing), to Living Cells : Prevention of, by Dimethyl Sulphoxide (Dr. J. E. Lovelock and Dr. M. W. H. Bishop), 1394
Damage (Hepatic), due to Acute Biliary Obstruction : Determination of Transaminase Activity in Dogs' Serum and Lymph after (Dr. P. Braun, Dr. M. Papp and Dr. I. Horváth), 48
Damage (Myocardial), due to Lymphatic Congestion : Changes in Serum Transaminase Activity following (M. Földi, Dr. P. Braun, Dr. M. Papp and Dr. I. Horváth), 1333
Damage (Radiation), in the Insect *Rhodnius* : Oxygen Deficiency and (W. F. Baldwin and T. N. Salthouse), 974
Damage (Radiation), in Stretched Rubber : X-Ray Diffraction Measurement of (Wesley E. Shelberg and Lewis H. Gevantman), 456
Damage (Spray), in Barley : Varietal Resistance to (J. Desmond Hayes), 551
Damblon, J., and others : Comparative Sensitivity to Radiation of Seeds from a Wild Plant grown on Uraniferous and Non-Uraniferous Soils, 1449
Dameshek, Dr. William (Schwartz, Dr. Robert, and) : Drug-induced Immunological Tolerance, 1682
Dan to Beersheba : From—Excavations in North and South Palestine, *review* by Peter J. Parr, 951
